TUESDAY, May 8th.—4.15 P.M., Dr. F. Craven Moore: Constipation.
FRIDAY.—4.15 P.M., Mr. J. P. Buckley: Demonstration of Surgical Cases.

VERSITY OF BIRMINGHAM.
MONDAY, May 7th.—4 P.M., Prof. F. H. G. Van Loon: A Study of Insanity Among Primitive Peoples in its Bearing on the Problem of Heredity.
THURSDAY.—4 P.M., Dr. L. G. Parsons: Recent Advances in Our Knowledge of Rickets and Allied Diseases. (First Ingleby Lecture.)

Appointments.

LER, W. M., M.B., Ch.B. Aberd., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Lochaber District (Sheriffdom of Inverness, Elgin, and Nairn).

lington Green Children's Hospital: MCMICHAEL, J., M.B., Ch.B. Edin., House Physician; and ALEXANDER, G. L., M.B., Ch.B. Edin., House Surgeon.

fying Surgeons under the Factory and Workshop Acts: MACIVER, I. H., M.B., Ch.B. Edin. (Fort William, Inverness); WHYTE, J. A., M.B., Ch.B. Aberd. (Aberchirder, Banff); MULLIGAN, J. A., M.B., Ch.B. Aberd. (Bervie, Kincardine); and MCKENZIE, J., M.B., Ch.B. Aberd. (Rhynie District, Aberdeen).

Vacancies.

Willesden, Park Royal Hospital, Acton-lane.—Res. 1st Asst. M.O. £430.
Woolwich War Memorial Hospital, Shooter's Hill, S.E.—H.S. £120.
Worcester General Infirmary.—Sen. and Jun. Res. M.O.'s. £180 and £120 respectively.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Bradford-on-Avon (Wiltshire), St. Margaret's Hope (Orkney), Slough (Buckinghamshire) and Buckhaven (Fifeshire).

Births, Marriages, and Deaths.

BIRTHS.

BRADE-BIRKS.—On April 22nd, at a nursing home, Manchester, Hilda Kathleen Brade-Birks, M.Sc., M.B., Ch.B., L.R.C.P., M.R.C.S., D.P.H., wife of the Rev. S. Graham Brade-Birks, of a daughter.
HUNTER.—On April 29th at 117, Greencroft-gardens, N.W., to Mathilde, wife of Donald Hunter, M.D., M.R.C.P.—a daughter.
MACLEOD.—On April 25th, at Wargrave, Clevedon, Somerset, the wife of Dr. Macleod, of a daughter.
MORTIS.—On April 24th, at Shenley, Herts, the wife of Dr. R. H. Mortis, of a son.
SPROTT.—On April 27th, at a nursing home in Windsor, the wife of Norman A. Sprott, M.D., M.Ch., F.R.C.S., of a daughter.

MARRIAGES.

TUCK—ELMITT.—On April 25th, at St. Peter's, Littleover, Derby, Wilfred Henry to Mary Hermione Elmitt, M.B., B.S., only child of Mr. and Mrs. W. Elmitt, Lindum, Littleover, Derby.

DEATHS.

AGATE.—On April 23rd, at Queen Alexandra Hospital, Marseille, France, Henry St. Arnaud Agate, M.C., M.R.C.S., L.R.C.P.
BRIGGS.—On April 20th, at St. Mungo's Croft, Aspatria, Cumberland, Dr. William Perry Briggs, aged 72 years.
CHURCH.—On April 27th, at Woodside, Hatfield, William Selby Church, Bart., K.C.B., M.D., in his 91st year.
CORKERY.—On April 28th, at Alfreton, Timothy Corkery, M.D., aged 65.
LYNN-THOMAS.—On April 30th, 1928, at Ruthven, King Ussie, Inverness-shire, Ivan, the beloved husband of Dorothy Guthrie, and the only son of Sir John and Lady Lynn-Thomas, Llwynduris, Llechryd, Cardiganshire. Aged 31.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

HAIR IN FORENSIC MEDICINE.

CASES often occur in which the chief issue, or one of the chief issues, hangs literally on a hair. A murder has been committed and the arrested man has hairs on his clothing, or the weapon found in a suspect's possession has hairs adhering to its bloodstains; if the hair can be shown to belong to the victim the connexion is almost irrefutable. Again, a dispute arises over a consignment of furs; any evidence on the nature and quality of the hairs may determine the finding.

A study of hair from this aspect, if it is to be of any evidential value, must be as complete as possible, and the necessary microscopical examination is a formidable task. The technique was described at the Medico-Legal Society's meeting on April 26th by Dr. John Glaister, junior. With co-workers he has collected samples from every order, sub-order, and family of the mammalia and taken photographs of their transverse and longitudinal sections. The collection of photographs and specimens, adequately catalogued, is now at the disposal of those whose duty it may be to identify hair for the purposes of justice. The number of samples examined was about 2500. Human hair was studied in detail and samples were taken from all parts of the body of male and female persons of various ages. The medico-legal examination of a sample is a complicated process. It takes account of colour, length, texture, breadth; and the shape and condition of the tip, which may be clean-cut, rough-cut, or torn, and in which a certain amount of regeneration may have taken place. The condition of the base may constitute material evidence; the bulb will often show whether a hair has been pulled out or has fallen out. The cuticle may be smooth, serrated, or imbricated, according to the species of the animal which grew the hair, and the cortex and medulla, and the contour of the transverse sections, vary considerably with different orders. The duck-billed platypus, the lowest mammal from the evolutionary standpoint, has hairs with an extraordinary shield-shaped tip and a rudimentary medulla with scattered pigment; the cortex has longitudinal fibres with irregular granular spots. The spiny anteater and the elephant's tail are alone in possessing hairs composed of a hard substance like keratin, those of the former having a cigar-shaped tip. The hairs of deer have a peculiar stiff wave and small needle-like projections; the cross-sections show a honeycomb or lizard-skin arrangement of cells with a fine filmy lace-like centre. Giraffes are the only animals which provide hair with almost circular contour; seal hairs have a unique cigar-shaped section and hartebeest hairs a section rather like a kidney.

The hairs which possess the greatest legal importance are nearly all quite distinctive. Bovine hair and horsehair have a very concise and irregular pigment; rabbits have hair with a narrow cortex and a proportionately broad medulla. Rabbit hair is bone-shaped, broad at the ends and narrow in the centre, and the ends are filled with small cells that fit into one another. Sea animals have hair with a jagged, irregular cuticle that produces "felting." Shrew hairs have a medulla that alternately contracts and expands throughout their length, and a tail-like formation at the tip. Naturally curled hair shows an overlapping of the layers of the cuticle, like slates on a roof, which is absent in an artificial curl.

Hair from the primates is like that of man, but presents differences which the expert can appreciate without much difficulty. At the Medico-Legal Society's meeting Dr. Ainsworth Mitchell said that a negro's hair resembled a great ape's much more than it resembled a European's. When human hair goes grey the medulla becomes fragmentary and irregular. Hair re-growing after being cut has a little shoot or process at the tip that is quite distinctive. Dyed hair has the appearance of being varnished and of being covered with a film that obscures the original pigment and the layers. Pubic hair is very wiry and resistant, and all but the fairest has a very dense uniform medulla. It is similar to moustache hair, but the latter has an irregular triangular contour. Wiriness goes with angularity in section. Age can be estimated approximately, but not accurately, and a quantity of hair is necessary. Nits, food, wax, sweat, and other extraneous matter may be of great legal importance, and the presence of arsenic in particular parts of the hair may indicate the period at which the drug was taken. The national value of a collection like Dr. Glaister's, backed by his knowledge, is considerable, and it will be of great assistance in identifying doubtful samples of hair. He is now engaged on the comparative study of the hairs of different races.

COLLECTIONS OF REPRINTS.

THE corporate spirit animating certain hospitals and institutes whose staffs are actively prosecuting research in different directions, manifests itself in the periodical collection of published articles into one volume. These are o widely separate in scope and in value. The grey to issued by the Rockefeller Institute are well known in libraries. The London School of Hygiene and Trop Medicine provide blue-books of collected addresses laboratory studies and, in recent years, the Middle Hospital has followed the same practive. Reprints various sizes, bound together, in the volumes issued f this hospital, make the book less convenient to ha than are the more extravagant volumes where the arti have been reset. This year's crop of some 40 orig publications makes a substantial and creditable volum

AN INDIAN MEDICAL OFFICER OF THE PAST

Joseph Hume, surgeon in India and a leader of Radical Party in the House of Commons, deserves to remembered by the medical profession. The orpha son of a shipmaster of Montrose, born in 1777, and v difficulty educated as a doctor, he was in 1797 appoin assistant surgeon in the sea service of the East In Company. A man of great industry, no work came am to him, and it is noted that he quickly mastered Hindust and Persian. So when he was sent to the Mahratta W in 1801, as surgeon of a Sepoy regiment, we find employed as interpreter to the column commander. T gave him an opening of which he made such good use to win the special commendation of Lord Lake, Commander-in-Chief. In those days work of this kind not go without reward; besides, he did not neglect his interests; and in 1807 he was able to retire from the ser with a fortune of £40,000. He travelled in Europe and Mediterranean for a couple of years, translated the "Infer into blank verse, and in 1812 entered Parliament, of wh he remained a Member, off and on, for 30 years. As on the Radical Party he was indefatigable in exposing pu extravagance, and the Dictionary of National Biogra ascribes to him the inclusion of "retrenchment" in t party's programme. He resisted flogging in the Army, press-gang, and imprisonment for debt, and tried to end East India Company's monopoly of trade with India, t trade might increase and greater employment be caused England. Twice he was Lord Rector of Aberdeen Univ sity. He roused, of course, much opposition, but when died in 1855 Lord Palmerston, moving a new writ Montrose, said that Joseph Hume had disinterestedly tak the lead in almost every branch of improvement, that had an industry nothing could tire, and vast perseveran There was no bitterness in his conflicts; "our friend wa man on whom we must all look back with admiration a regret." Another Member, with unnecessary pessimis added that if ever there was an honest Member of Par ment Hume was one, and another said he had ne made an enemy or lost a friend.

X RAYS IN THE TREATMENT OF ASTHMA.

THE results of treating asthma by so-called spec methods are not so successful as to discourage more empiri therapeutics. Treatment by X rays still has its support and some results of this method have lately been publish by Vallery-Radot and his colleagues [1] in France. Af discussing the methods and results of previous workers th describe 64 cases of their own in which the spleen and lun were irradiated, the length of treatment varying accordi to the progress made. Nineteen of the patients w completely cured, it is said, for 12–18 months, whilst 16 w relieved, and 29 did not respond at all. The authors a unable to explain the beneficial influence of X rays, b suggest that they may act by modifying the acid-ba balance of the organism. They do not mention the probab effect of suggestion, which often plays an important pa in the relief of asthmatic symptoms. Nausea, vomiting, a exacerbation of the asthma sometimes occurred aft prolonged treatment, but they did not notice the eosinophi and effects on expectoration which have been reported other observers. The treatment is, they consider, of gre value in some cases, though in others it is of little us Unfortunately the method of trial and error is admitted the only means of distinguishing between the two groups

THE YEAR OF AMBROISE PARÉ'S BIRTH.

Blancus writes: In a footnote to Prof. Meyer-Steineg interesting article on the treatment of gunshot woun (THE LANCET, April 21st, p. 840) it is stated, in agreeme with Mr. Stephen Paget's biography, that Ambroise Pa was born in the year 1510. For many years 1517 was giv in French and English reference books as the year of h birth, and Dorland's dictionary mentions 1509. Is it no decided that 1510 is correct?

Linacre Lecture

ON

LINACRE'S INFLUENCE ON ENGLISH MEDICINE.

Delivered at St. John's College, Cambridge, on May 5th

BY SIR GEORGE NEWMAN, K.C.B., M.D. EDIN., D.C.L., LL.D.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

[Sir George Newman began his address with an eloquent description of Florence as the centre of cultivation of learning and art, when "there came to this beautiful city of flowers and colour and song about 1485 a grave, studious, and sober-minded Englishman, Thomas Linacre."]

THE LIFE AND WORK OF LINACRE.

Linacre was born at Canterbury probably in 1460, and went to the monastery school at Christ Church, Canterbury, under the priorship of William Tilly, more commonly called Selling, from the name of the Kentish village of which he was a native. Selling was a Fellow of All Souls and an old pupil of Politian at Bologna, and as presiding monk in the Canterbury monastery the tutor and preceptor of Linacre, who at the age of 20 was removed to Oxford. There he was elected in 1484 Fellow of All Souls, which became at that time an English home of Greek learning. Under Vitelli he studied Greek in company with Grocyn and William Latimer, and became an accomplished scholar. When Archbishop Warham appointed Selling, the Prior of Christ Church in Canterbury, as ecclesiastical ambassador to Rome, Linacre accompanied him and by him was introduced to Politian. Whether or not he sojourned en route at Bologna, Linacre soon found himself in the midst of the Platonic Academy at Florence, patronised by Lorenzo de Medici, the companion and fellow student of his sons, Piero and Giovanni, and the pupil of Chalcondyles and Politian. We do not know the exact pursuits or studies of Linacre; we only know he stayed in Florence for more than 12 months, that he associated with the *habitués* of the Medician court, attended the Academy classes and disputations, read in the libraries, shared in the pleasures and gaieties of Florence and became intimately acquainted with Chalcondyles, Politian, and Ficino, the leaders of the Academy, and brilliant friends of Lorenzo de Medici. We cannot here enter into the scholarship and lives of these four men, but we cannot doubt that they left an enduring mark, the love of learning, upon him. It is as if he came out of the shades of scholasticism at Oxford into the sunlight of a larger life and a wider purpose. Like Saul of Tarsus on the road to Damascus, or like Mahomet on Mount Hira, he saw a new light.

From Florence Linacre, now disciple of Politian, repaired to Rome. A perusal of ancient manuscripts obtained in the libraries of the capital had been one great motive of Linacre's journey. One day he was reading in the Vatican when Hermolaus Barbarus suddenly approached the place where he was seated, and introduced himself. This accidental interview began a firm and lasting friendship which was afterwards strengthened by a similarity of disposition and pursuit. Dr. Noble Johnson says that "of all the acquaintance which Linacre formed in Italy, this was perhaps the most distinguished, and the value of the friendship was enhanced by the literary celebrity of the individual with whom it was contracted." Who was Barbarus? He was born in Venice in 1454, son of a senator, grandson of a doge, and deputed envoy, and subsequently Ambassador, to Rome from the States of Venice, and who on account of services rendered was nominated by Pope Innocent VIII. to be patriarch of Aquileia. For accepting such preferment he was proscribed by his government, but was residing in Rome when Linacre arrived. Barbarus, indifferent to worldly honours: acknowledged but two masters, Christ and letters." Above all, he was a student of scientific and medical literature, a devoted translator of Aristotle, Dioscorides, and Pliny at Padua, and held a chair in that University. He was the vigorous critic of Averroistic Aristotelianism. He died of the plague in 1494, aged 40.

On leaving Rome Linacre proceeded to Venice to seek the acquaintance of Aldus Manutius, a disciple of Aristotle, and the master printer of Greek editions, who played so large a part in the struggle between Hellenism and Arabism. From Venice Linacre went to Padua, where he first really studied practical medicine, and took the doctorate degree. Thence by Vicenza and through the Cevennes he returned to London. He is believed to have sat at the feet of the celebrated Italian physician Leonicenus during a brief sojourn at Vicenza.[1]

Happy is the student who at an early stage in his studies receives the inspiration of great purpose and the contact of great minds. It is the dynamic of all true education. Linacre took with him to Italy a scholastic grounding in the classics; he brought back with him a living comprehension of the service which pure Hellenism could render to English Medicine, of the essential importance of Aristotle, and of the necessity of a reorientation of medical knowledge as transmitted by the Arabs. The Florentine Academy repudiated Arabist teaching. We must not forget that 450 years ago a training in medicine in Western Europe meant a course of reading and disputation on Hippocrates, Galen, and Avicenna. In the first year the student usually read the first Canon of Avicenna and the ninth book of Rhazes; in the second year the *Ars parva* of Galen, and the fourth book of Avicenna; in the third year the aphorisms of Hippocrates, the works of Dioscorides and Commentaries on Avicenna. Medicine was taught as a branch of philosophy after the style of Averroes. Such a course Linacre had pursued at Oxford and in Italy. He went out a scholar, he returned a doctor of medicine. It was not until the sixteenth century that the study of medicine dealt directly with the body of man and was based upon experimental science.

When Linacre came back to England he settled down again at Oxford, but as a teacher rather than an undergraduate, as a translator rather than a student, as a medical reformer rather than a schoolman. He was incorporated as M.D., and with Grocyn and Lilly he was recognised as one of the pre-eminent restorers of Greek scholarship in England. He was, in fact, the first. He tutored Sir Thomas More, who came up to Oxford in 1499, and about the same time he had an even more distinguished pupil in Erasmus, during his first visit to England. In 1501 he became tutor to the young Prince Arthur of Wales, while temporarily at Oxford, and subsequently he became physician to Henry VIII. This complimentary appointment brought him to London, where he resided at the Stone house, Knightrider-street, near the court at Bridewell, in the vicinity of St. Paul's, and introduced him to a London medical practice, which though limited, was in the highest circles. The routine practice of medicine was in the hands of apothecaries and quacks. In accordance with the custom of the time, Linacre was scholar, physician and priest, and was ordained by his influential patrons to a number of non-residential livings.[2] His priestly duties do not appear to have

[1] See Life of Thomas Linacre. J. Noble Johnson, 1835; and edition of Linacre's Translation of Galen's De Temperamentis. By J. F. Payne. 1881.

[2] These included Rector of Mersham in Kent, 1509; a prebendary stall in Wells Cathedral, 1509; Vicar of Hawkhurst in Kent, 1510; a canonry and prebend of St. Stephens, Westminster, 1517; prebend of South Newbold, York, 1518; precentor of York, 1519; Rector of Holworthy in Devon, 1518; Rector of Wigan in Lancashire, 1520. The Master of St. John's informs me of yet another ordination of Linacre—namely, that of Rector of Freshwater, 1520. The episcopal records of Winchester show that "Thomas Linacre, Doctor of Arts and Medicine," was instituted Rector of Freshwater in the Isle of Wight, August 8th, 1520, and resigned with a pension in 1522. The patrons at the time were the Prior and Convent of Domus Jesu de Bethlehem de Shene. In the seventeenth century the Archbishop of York conveyed the advowson to St. John's College, Cambridge.

interfered with his medical practice, his attendance at Court or his translation of Galen. Linacre's residence in Oxford, before and after his visit to Italy, extended to 21 years, and his life in London covered 23. He died in 1524 in his sixty-fourth year, and was buried in St. Paul's Cathedral, but the monument erected by Caius in 1557, and the grave itself, disappeared in the conflagration of 1666.

English Medicine in the Fifteenth Century.

Medical practice in England in the time of Linacre was Arabic in origin. The Byzantine influence had been authoritative from Bede to the Norman period, and was succeeded by Arabian doctrine until the Reformation. Jews, priests, and Franciscan friars were the leading practitioners. It was reported to Parliament in 1511 that the greater part of these practitioners had neither insight nor learning; and that "they used sorcery and witchcraft to the hurt, damage and destruction of the King's liege people, most especially of those that cannot discern the uncunning from the cunning." The plague and leprosy were the formidable diseases, both favoured by "famine pestilences" due to bad harvests. The lesser maladies of the Middle Ages had in them a large element of hysteria or psychoneurosis, so that faith came not amiss in the course of treatment. The extant leech-craft provided for consumptives, cancers, stone, gout, St. Vitus's dance, epilepsy, catarrh, ague, dropsies and jaundice, fluxes and ruptures, gout and rheumatism. The resources of surgery were few and the instruments simple, but splints were used, heat was applied by cauteries or hot bricks, and it was known how to staunch blood, extract missiles, reduce dislocations, and perform simple amputations. The resources of the native herbals were extensive and, in the sixteenth century, numerous excellent editions of these herbals were published. The physician in Chaucer was grounded in astronomy, and astrological lore played a large part in the times and seasons of treatment as well as its character. The apothecary was of long standing and an earlier representative of medicine than the physician. He was, Bullein said, the physician's cook. Yet he was not guiltless of other and worse deeds, for he was a seller of poisons. He it was whom Romeo sought—

> "I do remember an apothecary,
> And hereabouts he dwells, which late I noted
> In tatter'd weeds, with overwhelming brows,
> Culling of simples; meagre were his looks,
> Sharp misery had worn him to the bones:
> And in his needy shop a tortoise hung,
> An alligator stuff'd, and other skins
> Of ill-shap'd fishes; and about his shelves
> A beggarly account of empty boxes,
> Green earthen pots, bladders, and musty seeds,
> Remnants of packthread, and old cakes of roses,
> Were thinly scattered to make up a show." [3]

In the fifteenth century leprosy was no longer prevalent, but in September of the year in which Linacre left Oxford for Florence (1485) a strange and fatal malady, known as sweating sickness, broke out in London, believed to have been introduced by the mercenary troops of Henry Tudor's expedition landing at Milford Haven. It was like an autumn influenza and did not recur in epidemic form until 1508, then again in 1517 and 1551. It was a subject of correspondence in the letters of More and Erasmus, and Wolsey was one of its victims. It was, of course, hailed as a "new" disease as influenza and certain nervous disorders have been in our own time. The plague, the leprosy, and the sweat proved the necessity of invention of sanitation. In 1388 the first Sanitary Act ever made in England was passed by the Parliament of Cambridge. It followed the earlier sanitary ordinance of Edward III. in 1371, and was succeeded by others in the fifteenth century. Before Linacre's death it had become a national custom, initiated by royal decree, to practise notification of infectious disease, quarantine, the marking of infected houses, and scavenging and sanitary inspection. The medical profession, however, were not yet identified with epidemical observations, sanitation, or preventive medicine. Such patients as they had were amon the well-to-do, who needed not public assistanc Linacre left no clinical records of extant diseas though he had ample opportunity. But the same true of other well-known court physicians of the tim The barbers and chirurgeons were occupied with the lancets, the apothecaries with their alchemy ar simples, and the physicians with scholastic learning

The Domination of the Arabs and Schoolme

When Linacre returned from Italy, English medici was dominated by the Arabic interpretation science. It was introduced to England not later tha the twelfth century by the Jews and by Arab medical writings, the principal authors of which a familiar to us in the catalogue of the library Chaucer's physician.[4] Sir Norman Moore has to us that the Arabian medical writings were used al in Ireland in the fourteenth and fifteenth centuries and Henry VIII. advised Wolsey to take "the pil of Rhazes" as safeguard against the sweat. Throug out Britain it was a time of fossilised Arabism ar effete scholasticism, which had remote origins. T century of Islamic invasion of the West (622–73 remains one of the wonders of the world. It starte with the conversion and flight of Mahomet; by 6 the Arabs had conquered Egypt and destroyed f the second time the Alexandrian Library. Abdalla and Musa, and their followers, marched across Nor Africa, capturing the old cities of Carthaginian rul by 710 Tarik had invaded Andalusia; within 20 yea the Moors, having possessed the land of Cordo and Seville, advanced over the Pyrenees to Ca cassonne, Narbonne, Avignon, and to Toulouse ar Bordeaux; only at the gates of Tours were th stopped by Charles Martel in 733. If he had faile the history of Europe would have been very differe

Indeed, as it was, the Arab invasion was so per trative that Jewish and Arabian influence becar greater and more insidious even than the march the Saracen hosts. From the year 750 the Easte Caliphate flourished for 500 years and the Weste beginning at the same time, for almost as lor In the reign of both, Arabic learning became dominar It had established itself as the vehicle and chan of Byzantine Greek medicine, which it derived fro its ability to assimilate the Syrian and Jewish medici of the Nestorians.[5] First Gondisapor and th Bagdad, took the place of Edessa—the origi Nestorian medical centre before 489—as the princi medical schools of the East and the influence of t great Arabian physicians, Rhazes of Bagdad, Abbas, and Avicenna of Bokara, spread wherev Arabian arms had won supremacy. The Canon Avicenna became in East and West the text-bo of medicine, carrying within its covers an inadequa and miscellaneous account of the learning of Hipp crates and Galen. The University of Cordova w founded in the eighth century and became the Bagd of the West. Of its leaders Abbucasis translat for Europe the works of Galen and Rhazes, a Avenzoar and Averroes those of Aristotle. T schoolmen of the Middle Ages carried on the traditi The trouble was that the tradition itself was fallacio The learning had come through Greek, Syria Persian, Arabic, and Latin, and in its translatio and retranslations had suffered almost as much by its Arabic transmutation.

The Arabs brought something of their own. W must not forget, for instance, that the first-ha clinical accounts of small-pox and measles were ma by Rhazes in the eleventh century and introduc en bloc into the Western medical literature. T

abs also brought their alchemy, their experiments, ir laboratory, their mathematics, optics, and ronomy, their exceptional faculty of deduction, ir immense love of learning—all these things iched their Greek acquisitions. But the acquisitions re overlaid with false conceptions of disease, with uperfluity of drugs, with astrological forecastings, d with their deep and inherent religious dogma, and this way both the Greek form and its spirit were t. Thus it came about that Hippocrates was gotten, Galenical doctrine became a static dogma, d Aristotle was mistaught. Aristotle, the son of a ysician, had been the father of biology as well as litics. He first laid down the rule and practice of serving Nature and following her ways. He became, Dante said, "the master of those who know." He t only based his natural studies on embryology and ıdered accurate records of what he found, but he t sought to formulate a basis for devising some laws nature, on biogenesis, on development, and on ysiological division of labour. He was free from gic and speculative "ideas," and eschewing that ich was unmeasurable became a "realist." He ıceived the universe to be a cosmos. Holding fast the rules of logic and keeping close to the facts of ual experience, he reached positive results, veri- ble by observation and experiment. Dealing with individual organism, as Hippocrates had dealt h the individual patient, he conceived a system of anic development. Though taught by Plato he ided teleological or supernatural explanations, t thus led men's minds to naturalism.

The principal Arabic translator of Aristotle was erroes, of Cordova, whose labours in the twelfth tury set a standard which covered Europe. He s known as the Commentator, and his "Colliget" s written about 1190. But the standard was not ely that of Aristotle, but an Averroistic interpreta- n of Aristotle. For Averroes had been reared in the trines of Islam, and interpreted the data of stotle from the Mohammedan point of view, ived from the sects of Islam, wholly antithetical to ek philosophy, and without apprehension of onalism. Averroes stands therefore always midway ween the theology of the schoolmen and the losophy of the Greek. He summed up his dogma wo cardinal doctrines, the eternity of matter and world (as distinct from the common belief that world was about to end) and the theory of the llect. "The first thing created by God," says Koran, "is intelligence," and by this term rroes meant the soul or anima. Renan summarised rroes for us by saying that he believed in "the nity of matter; the evolution of the seed by nt force; God infinite and indefinable; laws, re, necessity, reason; the impersonality of lligence; the emersion and reabsorption of the vidual man after death."[6] It was Omar yyam who said:—

> "I sent my Soul through the Invisible,
> Some letter of that After-life to spell:
> And by and by my Soul return'd to me,
> And answer'd 'I Myself am Heav'n and Hell.'"[7]

here is much in Averroes, both ancient and ern, that has stood the test of time, but the denial uman immortality divorced him from Islam as pletely as his quasi-rational basis of nature and eternity of the world separated him from the olman of Europe. He died in 1206 no man's d, for Averroistic Aristotelianism unwittingly used and misdirected the stream of new thought h Aristotle had originated. Aristotle had found support in Padua and the Venetian States, but in the Platonic Academy at Florence.[8] Before dawn of the Renaissance Florence and Venice sented the two poles of scientific philosophy as of n Italy. Florence swung in favour of ideals of and of platonic speculation and philosophy, ia and Bologna in favour of analysis, rationalism, and the naturalism of Aristotle. Averroes sought to combine both of them, and the schoolmen's transmutations of the Commentator misled Western medicine for 300 years.

But the Aristotelianism of Averroes was but half the problem faced by Linacre and the Oxford Reformers. For there was also scholasticism. It was in the thirteenth century that the English universities first arose, and the impulse created by the Crusades was diverted to the spread of learning. "The long mental inactivity of feudal Europe," said Mr. J. R. Green, "broke up like ice before a summer's sun. A new power had sprung up in the midst of a world as yet under the rule of sheer brute force." The new spirit led to "the great divide" in European scholasticism. The fundamental problem of scholasticism had been the objectivity versus the subjectivity of matter. Those who stood for the former were *realists*, those for the latter were *nominalists*, and for 200 years the battle of words between them had waged fiercely.

> "Myself when young did eagerly frequent
> Doctor and Saint, and heard great argument
> About it and about; but evermore
> Came out by the same door where in I went."[9]

But the emergence of Aristotle's science in Western Europe through the medium of the Arab translators was revolutionary. Until the beginning of the thirteenth century Aristotle had been known to the schoolmen only by his logic. From the advent of his science sprang a new impulse, and the ascendancy of the schoolmen of the early scholasticism, Roscellinus Abelard, and Peter Lombard gave way to that of the later scholasticism of Albertus Magnus and Thomas Aquinas the Dominicans, and of Ockham, Duns Scotus and Roger Bacon, the Franciscans. Too many of the translators of Aristotle had an imperfect knowledge of Greek as they had of the groundwork of science. Nevertheless the Toledo school of translators and many stray reporters transmitted and magnified the work of Aristotle in the western world. Thus Roger Bacon himself was stimulated. Though a schoolman he was progressive and became a true Aristotelian. the Father of the scientific method in England. His legacy was accuracy of method, criticism of authority. reliance on experiment. He also stood for the unity of truth. "All the sciences are connected," he said; "they lend each other material aid as parts of one great whole, each doing its own work, not for itself alone, but for the other parts." Two centuries before the Renaissance he declared that the whole course of man's intellectual development was not multiple but one, not discrete or detached, but continuous and interdependent. For Roger Bacon there was no Arabic breach. The Nestorian and Mohammedan schools of science in East and West were, to him, not only channels of Greek learning. but treasure houses which enriched it. "His aim," says Dr. John Bridges, "was induction leading to deduction, in order to construct."[10]

Linacre as Translator of Galen.

This, then, was the world of Linacre. There was the domination of Arabian medicine and there was the thraldom of the schoolmen. The fallacies of both stood in the way of progress and were awaiting reform. As we have seen, active medical practice occupied but a small part of Linacre's work after his return from Italy. Fifteen years were spent at Oxford before he removed to Bridewell about 1503. and 20 more years remained to him. Both at Oxford and in London he devoted the major part of his time to grammar and translations, and this was his first great contribution to the Renaissance. But it was not merely scholastic; it was purposive. It was designed to bring men's minds back to Aristotle. Stimulated by Barbarus, Linacre's ambition was to coöperate with Grocyn and Latimer in translating the extant writings of Aristotle direct from the Greek; as this joint task proved impracticable he assisted

in preparing the famous Aldine edition of Aristotle 1497, and gave himself to translations of Galen. For Galen was a medical interpreter, whose writings were already in general use and acceptance; they constituted perhaps half of all surviving Greek medical literature, and covered every branch of medicine. The Hippocratic spirit was inadequately conveyed as the teleological explanations were overdone, blemishes in part responsible for the survival of Galen's books. But Linacre was a practical reformer, and by translating Galen he saw he would give to the English medical practitioner a vade mecum of immediate value, free from Arabic mistranslation and theological bias. He selected first, on the suggestion of Erasmus and as the basis of other works which he hoped to translate, Galen's treatise on *the preservation of health*, its foundation in nature, its art, its purpose, its priority over therapeutics. Then he took up Galen's *method of healing*, which was followed by his books on temperaments, on symptomatology, on the pulse, &c.[11] Thus he was responsible for six important works of Galen, that on the temperaments printed at Cambridge in 1521 being one of the first books printed here, and possibly the first in Greek type. Linacre was grammarian, humanist, priest, and scholar-physician rather than practitioner of medicine, and he used the printing press, as Albrecht Dürer used his engraved blocks, to cover Europe with his ideas. By this means he taught as grammarian the exact use and connotation of words, took men back to the original sources of scientific literature, and silently appealed for the use of reason instead of mere authority. Though his lesson-book on grammar prepared for Dean Colet's school at St. Paul's failed to meet with approval in England, and his translation of the "Sphæra of Proclus," the Alexandrian neo-platonist, was little more than a curiosity, his scholarly translations of Galen changed the direction of the schoolmen and countered the effect of the Arabian domination. They were more valuable than the Arabian translations, less petrifying and static, more inspiring and potential, and destined to open the new book of the science of anatomy and physiology. Galen himself was less Galenical than the Arabs had made him, and Linacre's translations removed the reproach which medicine derived from the blemishes of its Arabic form and contributed to the introduction of the Hippocratic spirit. Haller attributed the advance of human anatomy in the sixteenth century to the revival of humanistic learning and the invention of printing. Within a generation after Linacre's death the whole conception of human anatomy and physiology had changed in the medical schools of Europe, and your own Charles Creighton in his classic "History of Epidemics in Britain" said that such translations as those of Linacre opened the way a century later to the standard clinical contributions of Willis, Sydenham, and Morton. Linacre's aim was to revive medicine with Greek learning from its pure source in the same way as literature and philosophy was reviving from the Renaissance of the classics. Inspired at Florence as a Platonist, he became the forerunner of Aristotelian medicine in England, and the principal initiator of the scientific movement which was the turning-point in modern medicine.

Foundation of the College of Physicians.

But the turning-point could not be reached only by translations of ancient learning. New learning must be acquired, a new orientation of English medicine other than Arabic must be established, a new spirit such as had awakened Italy must be sought and found. Though a generation had passed since Linacre returned from Florence and Padua he had not forgotten the energising effect of the close personal contact with great minds, nor could he ever escape from his own profound conversion of mind and heart, a transformation which had been steadily confirmed by the passage of events. The world itself was larger. Since Linacre was in Italy, Columbus had discovered America, Vasco da Gama had rounded the Cape, Ferdinand had driven the Arabs from Granada and the Moorish Kingdom in Spain was extinct, Luther had nailed his theses to the church door at Wittenberg, and Thomas More had published his "Utopia." We must not think of Linacre only as grammarian and humanist; he was like his friends, a man of affairs, and his business was to reform English medicine. He knew of its plight and chaos; he knew it was not a distinct profession and that medical practice was little better than an empirical, illiterate, and mechanical art. Having by his translations of Galen given it the means of the new learning, he set to work to devise a method for its organisation. We do not know what share, if any, Linacre had in the passage of the Medical Act of 1511, but it is certain that it stirred him to action. That Act was the second great step to medical reform after the Charter of the Barber-Surgeons in 1461. It provided that no one should practise as physician or surgeon in London or within seven miles of its walls except he be examined and licensed by the Bishop of London or the Dean of St. Paul's with the aid of competent doctors of physic as assessors, and that in the provinces the duty of licensing medical practitioners should rest similarly with the Bishop of the diocese. This was better than the previous unlicensed confusion, but Linacre desired to liberate medical practice from the control of the church as well as to lead it into the paths of Plato and Aristotle and the freedom of Hippocrates. In a word, he saw that what was needed was the endowment of medical lectureships at Oxford and Cambridge, and the establishment of a central academy of medicine, which should be charged with the duty, foreseen by Frederick II. in the thirteenth century, of licensing physicians who were medically competent and whose education had been based upon literature and philosophy. This was the origin of the foundation of the Linacre lectures at Merton and St. John's for the public exposition of Hippocrates and Galen, and in September, 1518, by royal letters patent, a Charter was granted by Henry VIII. to Linacre and five other physicians for the foundation of the College of Physicians of London and for the regulation of the practice of physic in London and for seven miles round, and the punishment of offenders. Four years later these privileges were confirmed by statute and extended to the whole country. Linacre became the first President of the College from 1518 until his death in 1524; to his munificence its establishment was due, and in his house its meetings were first held.

Beside the ostensible object of providing a statutory and scientific basis for qualification in medicine the College of Physicians exerted a powerful influence on its science and art. It liberated it from the control of the Church; it exempted it from the leaden rule of orthodoxy which dominated the universities; it brought the competent medical practitioner into the learned world; it encouraged English physicians to study in the universities of Europe and brought foreign physicians into English culture; it was the first systematic plan of education prescribed in England for a faculty of medicine. Out of it great things were to come.

> "The congregated college have concluded
> That labouring art can never ransom Nature
> From her inaidable Estate." [12]

Within a century it had built for itself a comprehensive institution for scientific advancement comprising anatomical and special lectureships, a phys-

[11] Linacre's published translations were as follows: Proclus de Sphæra (Aldus Manutius, Venice), 1499; Galeni De Sanitate Tuenda (Rubens, Paris), 1517; Galeni Methodus Medendi, vel de morbis curandis (Maheu, Paris), 1519; Galeni Pergamensis De Temperamentis (Siberch, Cambridge), 1521; Galeni Pergameni De Naturalibus Facultatibus (Pynson, London); 1523; Galeni Pergameni De Pulsuum Usu (Pynson), 1523; De Symptomatum Differentus Et Causis (Pynson), 1524; Rudimenta Grammatices (Etienne), 1533; De Emendata Structura Latini Sermonis (Pynson), 1524.

rden, a museum, a library, and the publication of e London Pharmacopœia for the standardisation of ugs.

THE BEGINNINGS OF THE BRITISH PHARMACOPŒIA.

The letters patent granted by Henry VIII. which nstituted the College of Physicians were confirmed an Act of Parliament in 1523, which particularly ovided for the supervision and scrutiny of every nd of medicine prescribed by physicians practising thin the City of London and a radius of seven miles ereof. The means proposed for such supervision is that certain persons appointed by the College ould be authorised to enter the premises of all othecaries and destroy any defective drugs found ere. They were to be assisted by the Warden of the stery of Poticaries within the City, and a few years er the College invoked the aid of the Warden of the ocers. A hundred years later, in 1618, some of these wers were also conferred separately on the apothe-ries, and this was confirmed by the Apothecaries t of 1815. This idea of Linacre and his friends was w to English medicine, though it had ancient abic origins. Thus was introduced for the first ne in this country the principle of pharmacological ntrol of substances used for the treatment of disease. e records of the College show that the publication a Pharmacopœia under its auspices was discussed the sixteenth century; but it was not until 1618, years after the Nuremberg *dispensatorium* of lerius Cordus and a century after the foundation of College, that the first London Pharmacopœia was ued. It was dedicated to James I. and proclaimed a Royal Proclamation which required, charged, and nmanded all apothecaries not to compound or make dicines in any other manner than that authorised. is first London Pharmacopœia included more than housand articles, "many of an extraordinary and n revolting character," and 900 preparations and npounds.[13] The ancient pharmacopœias of the lege of Physicians were the forefathers not only of modern pharmacopœias, issued since 1862 by General Medical Council instead of the College, they were also the parents of the famous ies of Acts of Parliament which in our own time ve dealt with the sale of food and drugs, the ulation of pharmacy and poisons, and the subse-nt control of foods, dangerous drugs, and thera-tic substances. The Therapeutic Substances Act, 5, and its Regulations passed by Parliament last r, which for the first time provide for the standard-ion of biological as distinct from chemical drugs, the direct and youngest descendant of the first rmacopœia of the College of Physicians, which se out of Linacre's far-seeing though primitive ervision of the drugs and medicines used by sicians and apothecaries at the time of the naissance.

he private library of Linacre was the nucleus and ndation of the College library which became the ository of many precious legacies from William ert, Matthias Holbosch, Sir Theodore Mayerne, d Dorchester, Selden (who left his Arabic medical nuscripts), Elias Ashmole, Matthew Baillie, Harvey, others. It became a storehouse of the literary sterpieces of medicine, and though much was royed by the Fire of London in 1666, much ained.

he "Anatomy Lectures" were delivered on the ian model from an early period in the history of College, and about the middle of the sixteenth tury dissection of the body was performed. The ual Harveian oration exhorting the Fellows of the ege "to search and study out the secrets of ure by way of experiment, and, for the honour of profession, to continue in mutual love and affection ng themselves," began in 1656, the year before that Harvey's death. It was established and endowed Harvey, was to be accompanied by a feast, and fter days became in large degree commemorative Harvey himself. The Lumleian surgical lectureship was first established by Lord Lumley and Dr. Richard Caldwell in 1581; the Goulstonian lectureship in pathology in 1635; and the Croonian physiological lectures began in 1749.

LINACRE'S EARLY SUCCESSORS.

More germinal than the actual achievements of the College has been the Greek spirit it embodies. Linacre was not himself an investigator or research worker, but he was the introducer of the spirit of the Renaissance to English medicine, and he designed his College for its growth and cultivation. During the last few years of Linacre's life there was a Fellow of Corpus Christi, named Edward Wotton, who followed in the footsteps of Linacre in the study of Greek at Oxford and medicine at Padua. He became President of the College in 1541 and was the first of the English physicians who applied themselves to the Aristotelian principles of biology. Gesner and Haller spoke well of him, and his text-book was the first printed book on zoology by an Englishman. It contains much from Aristotle and Pliny. There followed him in the presidential chair Dr. John Clement, Cardinal Wolsey's Professor of Greek at Oxford. He had been brought up in the household of Sir Thomas More, to whose children he was tutor. Like Sir William Butts, Dr. Chambre, Dr. Fryer, Dr. Huicke, and Dr. Owen, who became distinguished Fellows of the College, he was associated with the court of Henry VIII. and carried on the Linacre tradition. The essence of that tradition was embodied also in John Caius, of this University, who qualified as M.D. at Padua in 1541 and became Professor of Greek there for two years, being paid by noble Venetians to discourse upon Aristotle. He was a zealous collector of Greek manuscripts in Italy, and modelling himself on Linacre he was a translator of Galen, an editor of Celsus, and one of the first classical scholars in Europe. When at Padua he lived for eight months with Vesalius and caught from him his great method of anatomical teaching, which Caius first introduced into this country by his lectures in the hall of the Barber Surgeons shortly after his return from Italy. He was also, in one respect, a clinical observer as well as anatomist and naturalist, for he wrote the first account of the sweating sickness of 1551 from his experience of the outbreak at Shrewsbury. He was the refounder of Gonville Hall as Gonville and Caius College, of which he became Master in 1559, and he built the four College gates of Humility, Virtue, and Wisdom, which led to that of Honour. For nine years he was President of the College of Physicians. "The effects of Linacre's teaching," wrote Sir Norman Moore, "are shown in the life of Caius. Both men in their humility, their love of learning, their public and private generosity, are examples which have affected English physicians ever since."[14]

When Caius was living with Vesalius at Padua there was born at Colchester the man who is described by Lord Bacon as "the father of experimental philosophy" in Britain. This was William Gilbert, the illustrious author of "De Magnete." He had studied, like Linacre, in Italy for two or three years. He was a Fellow of St. John's, an M.D. of Cambridge, and became physician to Queen Elizabeth. He employed the leisure from his London practice in investigation into what he called "electrics," a property not only of amber, but of glass, rock-crystal, diamond, sulphur, and sealing-wax. This was the beginning of the use of the term "electricity" and the scientific foundation of magnetism which had been known since the thirteenth century. In 1600 he was President of the College and in the same year published his famous book of inductive philosophy, which records his numerous experiments and discoveries over 18 years. The reading of this book turned Galileo's mind to magnetism. A legacy in Gilbert's will showed his devotion to the College:—

"Item. I geve to the Colledge of Phisitians in London all my bookes in my Librarye, my Globes, and Instrumentes, and my cabinet of myneralles,"

[13] Munk's Roll of the College of Physicians, iii., 371–392.

[14] The History of St. Bartholomew's Hospital, 1918, ii., 407–420.

and in a parting legacy he remembers its Fellowship too—

"Item. I geve sixe poundes thirteen shillings foure pence the next quarter daye after my deathe to be bestowed by the Treasurer of the Colledge to make them a dynner." [15]

The greatest ornament of the College of Physicians and of English medicine also hailed from Cambridge, for William Harvey was at Caius College in 1593. Like Linacre he had spent his school days at Canterbury, and like him he took his degree at Padua (1602). He was physician to St. Bartholomew's Hospital and physician to the King. In 1615 he was appointed Lumleian lecturer at the College of Physicians, and his autograph notes of his first lectures in 1616, six days before Shakespeare died, are in the British Museum. They show not only the width of Harvey's classical knowledge, but also contain his first pronouncement of his discovery of the circulation of the blood, which was subsequently published in his immortal book, "De Motu Cordis" in 1628. He conquered envy in his life time, as Hobbes said, and lived to see his new doctrine established. He was a munificent supporter of the College to which he was devoted and to which he left his library.

Linacre, Clement, Wotton, Caius, Gilbert, and Harvey represent the kind of learning and the spirit of inquiry for the advancement of which the College of Linacre was founded. In the first century of its existence it brought together in a unified integration the constituent elements of the science and art of healing, the exposition of which was subsequently exemplified in Linacre's illustrious descendants, Glisson, Sydenham, Willis, and your own Heberden. To the philosophy of the ancients the College added a wider understanding of biology and physics; it introduced the natural study of anatomy and physiology; its pharmacopœia began systematic pharmacology and therapeutics; its observant practitioners opened the doors of clinical medicine; and Linacre's College of Physicians became the sole guardian of medical learning and education in England. It was humanist in origin but forward-looking in vision; it began as a corporate fellowship, but became the great mother school of English medicine; it sprang from ancient learning, but grew into the study of Nature and obedience to her laws; it echoed back to the Greeks, but called men forward to a new time and a new birth, passing away from textual and literal form to the larger occasion of the living purpose and spirit of the great masters.

The Oxford Reformers.

As the restorer of Greek learning in England Linacre exerted a remarkable influence upon the men of his time. He had distinguished pupils and friends. On the occasion of his first visit to England Erasmus was evidently impressed with the group of men who afterwards became known as the Oxford Reformers. We all remember his letter to Fisher: "When I listen to my friend Colet," he wrote, "it seems to me like listening to Plato himself. In Grocyn, who does not admire the wide range of his knowledge? What could be more searching, deep and refined than the judgment of Linacre? Whenever did nature mould a character more gentle, endearing and happy than Thomas More's?" [16] Sir Thomas More and Erasmus, whose famous translation of the New Testament was published in 1516, were among Linacre's pupils; Grocyn, the first teacher of Greek at Oxford, who followed the Peripatetic School, and Colet, who became Dean of St. Paul's, were his colleagues at Oxford; and Latimer and Lilly also shared his Greek studies. In after days, and before More had settled in Chelsea, several of them lived near each other in the vicinity of St. Paul's and the Charterhouse, engaged in different spheres in bringing about the English Renaissance from scholasticism. They stimulated each other, shared in each other's labours, marked each other's lives. In the church and i the State, in scholarship and in medicine, the Oxfor Reformers emancipated English thought. The discussed the reform of education, the amelioratio of the evil social conditions of the people, the mean and methods of propagating the Greek spirit i England. Their society was a Platonic academy and out of it grew More's "Utopia." "The Utopi will be found," says Mr. Seebohm, "to be in grea measure the expression of the views of the litt band of friends on social and political questions." It is inspired, he adds, by "a fearless faith in th laws of nature combined with a profound faith i religion." Nor was it merely a matter of confidence Before he became Lord Chancellor, More himse had been appointed by Parliament a Commissione of Sewers, and at his side there was the greates living authority on the compendius hygiene of Galen As a member of a group of practical reformers Linacr too, brought the genius of the group to the solutio of his problems. There is in his work unmistakabl signs of the humane statecraft of Sir Thomas More the Catholic religious liberty and piety of Dea Colet, the cosmopolitanism and wide learning o Erasmus. Above all, there is the inspiration o Barbarus. It would almost seem as if Linacr modelled his life on this extraordinary man whom h met so casually in Rome. Barbarus gave him mode and perhaps a standard of life for the regula student, turned his scholarly mind to medicine and confirmed him in the mission of Aristotle. Si William Osler used to say that a physician "ma possess the science of Harvey and the art of Sydenham and yet there may be lacking in him those fine qualities of heart and hand which count for so muc in life. Medicine is seen at its best in men whos faculties have had the highest and most harmoniou culture"; and thus he says many of the greates physicians have influenced the profession "less b their special work than by exemplifying those grace of life and refinements of heart which make u character . . . these have been the leaven whic has raised our profession above the dead level of business." [18] Of these Linacre was one. Whethe it was the flower of inborn character or contracte from his brilliant friends or otherwise acquired, hi personality comes down to us across 400 years wit an aroma and a virility alike creative, winsome an enduring.

The Foundations of Modern Medicine.

By piecing together the scanty records whic remain to us of Linacre's personality and achieve ments—his translations, his institutions, and himse —we shall find that like Petrarch he stood "on frontier that divides two peoples, looking both to th past and to the future." As a humanist he followe where others had trodden. He joined with them i awakening the spirit of man to his literary inheritanc Though a medical practitioner in a pregnant time he did not elucidate the processes of diseases; th great epidemics seemed to pass him by; he left n original work. But what he did as humanist an scholar-physician was, by adding to the heritag already there, to make possible the fuller interpretatio of the Greek spirit. Though he did not himself eve share in the consequent reconstruction, he laid th foundations on which we build, he sowed the seed which we garner the fruit. "The medieval heritag of Greek science and the Renaissance heritage Greek literature," says Singer, "proved barren themselves. It was not until the one fertilised th other than there was real and vital growth." That fertilisation was the work of Linacre and th Oxford Reformers; to carry on that work is the legacy to us. Their principal secular work whic remains to us is More's "Utopia." It is almost a tex book of elementary statecraft and preventive medicin

[19] The Dark Ages and the Dawn (Singer), chap. v. of Scien and Civilisation, 1923, p. 149.

None who read the 'Utopia,'" wrote Sidney Lee, can deny that its author drank deep of the finest pirit of his age. None can question that he foresaw ne main lines along which the political and social leals of the Renaissance were to develop in the ıture. . . . By the precept and theory of his "Utopia," ore cherished and added power to the new light." [20] is friend and preceptor Linacre was the first hysician to make practicable the ideas of Roger acon in English medicine. He could not, or did not, mself practise them, but he implemented them ithin the limitations of his day; and the spirit of s institutions has expressed itself in four centuries such way and form as to give us our present prehension of the splendour, the amplitude, and the ast scope of the science and art of medicine.

If it be permissible to attempt a generalisation it ight fairly be said that four advances in English edicine are indirectly attributable to Linacre's initial fluence. In the sixteenth century the Renaissance rried with it a return to Aristotle and to Nature; e previous expansion of anatomy under Vesalius lminated in the seventeenth century in the fuller derstanding of physiology under Harvey; the eat naturalists and medical practitioners of the ghteenth century, of whom John Hunter was chief, ought into application the new physiology and thology in searching for the actual causes, circumances, and natural healing of disease; and the neteenth century from beginning to end was the riod of the organisation of the profession of medicine, th by itself and by the State, for the welfare of the mmonwealth, an organisation initiated by the llege of Physicians. None of these four immense steps human progress was narrowly confined to the period its introduction, and indeed the twentieth century abodies them all. If we ponder upon this amazing ries of events we shall find in it not only the ermath of the Renaissance, but the philosophic sis and object of medicine itself. The fundamental rpose of medicine is not to cure disease but to event it. Even Linacre and Sir Thomas More ew that the future well-being of the English people y with simple methods of prevention. Yet the actice of that prevention is still widely disregarded. "In the world of Nature," said Balzac, "the methods e very simple. It is the result that is great."

The Oxford Reformers and their successors down to arvey seem to say to us: "Follow the Greek spirit, arch out the secrets of nature, find out by the perimental method her laws, and be obedient to em." That is the true science and the only wise atesmanship. It cannot be doubted that Jenner, steur, Lister, and Allbutt would have said the ne. It is this mode of approach which has given : (*a*) the return to Nature, (*b*) the application of ysiology, (*c*) the new knowledge of the cause and cumstance of disease and its healing by immunity, d (*d*) the organisation of science in behalf of the rvival and development of man. These, and not e particular methods of their application, are the ential principles of preventive medicine. The ways d means of its practice and organisation will be nifold and diverse; some will be discharged by the ysician, some by the layman, some by the comnity. Our path will take us into all fields of knowge and all spheres of human society. We shall rk in Aristotle's double track of the one into the ny and the many into the one.

> "It may be that the gulfs will wash us down;
> It may be we shall touch the Happy Isles."

In spite of Linacre and the greater explorers who llowed in his train, we in England have been slow learn the lesson of the Oxford Reformers that only the growth of mind and soul is a nation great and e, only by seeking the truths of Nature and integrati them into a unity can we rightly belong to the gdom of life.

[20] Great Englishmen of the Sixteenth Century. Sidney Lee. 07, p. 33.

RADIUM TREATMENT IN CARCINOMA OF THE MOUTH AND TONGUE.

BY G. E. BIRKETT, *M.C.*, B.A. CAMB., M.R.C.S. ENG.,

RADIOLOGIST, MANCHESTER AND DISTRICT RADIUM INSTITUTE; HON. RADIOLOGIST, CHRISTIE HOSPITAL FOR CANCER; LATE PATHOLOGICAL REGISTRAR, MANCHESTER ROYAL INFIRMARY.

DURING my first year at the Radium Institute 127 out of a total of 565 cases of malignant disease referred for treatment were suffering from carcinoma of the mouth and tongue. At the end of the year 16 per cent. of these patients were free from evidence of either local or metastatic disease, but subsequent examination of all the patients treated showed that the results were very sporadic and that a very trying reaction usually accompanied treatment. Needless to say, most of the cases were frankly inoperable, but the same applies to the majority of cases of buccal carcinoma seen in hospital practice. About 50 per cent. of the cases referred for treatment by radium are in the last stages of the disease. Often half the entire buccal cavity is involved and the tongue absolutely fixed, whilst metastatic deposits, also frequently fixed to the great vessels, are found on both sides of the neck. At the moment no attempt is made to treat this type of case.

Evolution of Technique.

In taking charge of treatment at the Manchester and District Radium Institute two and a half years ago I felt, therefore, that the problem of the treatment of this variety of malignant disease was a fairly pressing one. There seemed to be no doubt that a number of cures could be obtained, but with the methods in use results were uncertain. In an attempt to arrive at some common principle the records for a period of ten years were examined. The cases were under the care of Dr. Arthur Burrows. It was found that 51 out of a total of 812 cases were well for periods of time varying from one to nine years. It was impossible to compare the results with those of surgery, as practically all the cases were surgical rejects, but the fact that radium could accomplish that which surgery, with its comparatively perfected technique, could not, was impossible to ignore. The main point of the investigation was that in 80 per cent. of these apparent cures the method employed had been that of burying small, unscreened emanation tubes or seeds in the primary growth. These tubes are left in situ and are probably effective for about 14 days. Both β and γ rays are employed, but the common factor is a comparatively small dose per unit of application continued for a long period of time. The other methods previously employed consisted in the implantation of screened tubes for periods up to 24 hours. The tube strength varied from 10–12 millicuries per linear centimetre, and the screening from 0·3 mm. of brass to 0·3 mm. of platinum. The former screen allowed far too much β irradiation to pass through, and often caused a very painful and distressing reaction. The same criticism applies to the unscreened method—only more so. On the other hand, the method did produce results and, if the end justifies the means, can be condoned. It had a great vogue in America.

About the same time Régaud,[1] in a paper read before the first International Congress of Radiology in London, referred to results in carcinoma of the tongue which were frankly brilliant and, although I have not had the opportunity of seeing his work, I should like to pay tribute to him as a pioneer in this subject. He applied the principle of prolonged irradiation with a buried tube technique, but avoided the disadvantages of sloughing and necrosis by heavy filtration—viz., 0·5 mm. of platinum, which gives almost a purely γ type of irradiation. Hitherto at the Manchester and District Radium Institute emanation only had been used, but in view of the possibility that it might be better to use a source of irradiation of constant strength, two series of tubes containing radium

element were employed. In order that variation in screening could subsequently be obtained if necessary, removable platinum cells containing radium sulphate were employed. They measured 16 mm. in length and had a wall thickness of 0·2 mm. of platinum, and contained respectively 1 mg. and 2 mg. of radium element—i.e., 0·62 mg. and 1·25 mg. per linear centimetre. The cells were contained in pointed platinum needles, with removable screw caps, 29 mm. long and with a wall thickness of 0·4 mm., giving a total screenage of 0·6 mm. of platinum. This ensures a completely γ type of irradiation. The average period was 8–10 days, but as long as 14 days has been given. Where emanation was employed instead of radium element an initial strength of 2–2·9 mc. for the same length of tube, or a linear intensity of 1·25–1·80 was adopted. It must be remembered, however, that radium emanation tubes lose strength at roughly the rate of one-sixth per day. At the end of a week the linear intensities would therefore be 0·35 and 0·50 respectively. Thereafter the curve representing this decay flattens out considerably and approaches the horizontal.

The disadvantages of emanation, as compared with radium element, are obvious. Once measured and put in a sealed container, the strength of a tube containing radium element does not vary appreciably, at any rate during a lifetime. It therefore ensures a certain strength and a constant intensity of irradiation. At centres where large numbers of tubes are being used, the use of emanation requires constant measurement if accuracy of dosage is to be obtained; this means increased danger to the personnel, both from the general and the local effects of radium. A higher initial strength of tube must also be used, which increases the risk of tissue necrosis. Régaud has stated that it is an advantage to use a gradually decreasing intensity of irradiation, but I fail to see why this should be so, nor can I adduce any evidence from my experience. The great advantage of emanation is a purely financial one. If a tube of emanation is lost, then only the value of the screen need be taken into account.

In this article the sites treated comprise the buccal surface of the lip and cheek, the floor of the mouth, tongue, fauces, tonsil, and hard and soft palates. It is easy to insert and retain tubes in all sites save the hard and soft palates; the type of tube referred to above is definitely unsuitable for these sites.

There is no such thing as a "dose" in carcinoma of the mouth. The number of tubes used depends upon the size and extent of the lesion and is a matter of experience. Under a general anæsthetic the lesion is usually found to be more extensive than would have been expected from the clinical examination, and it is as well to remember this in ordering the tubes. As Régaud [1] says, failures are mainly due to an inadequate recognition of the probable extent of the primary lesion rather than to an absence of effect, and this accounts for the majority of recurrences at the primary site. As far as possible tubes are implanted in the growing edge of the tumour, but where the lesion is a very large one they are also buried in the tumour itself. The tubes are placed about one centimetre apart. Ligatures should embrace healthy tissue where possible, otherwise they tend to cut through prematurely.

Anatomical and Pathological Considerations.

The problem as a whole is a complex one, and it is impossible to refer to more than general principles. Implantation of screened tubes is adopted for the primary site, but there remain the lymphatic nodes and the intervening lymphatic tracts between these and the primary growth. Spread can occur either by permeation, by embolism, or by both. If spread is by permeation then treatment must be directed to all three zones, but the view generally held is that metastasis is usually embolic, in which case the main problem is the primary site and the lymphatic gland area only. Once the disease has reached the lymphatic gland area the field is much wider, as it is impossible to foretell accurately which group of glands will be affected. Broadly speaking, metastases from the floor of the mouth and the anterior third of the tongue will be in the submental, submaxillary, and upper deep cervical groups of glands; from the fauces, tonsil, and middle third of the tongue in the submaxillary and upper and lower deep cervical groups, and from the base of the tongue in the upper and lower deep cervical groups. When a lesion has crossed the mid-line infection of one or both sides can occur.

The ideal method would be an external application which would cover the whole of the lymphatic drainage area on both sides of the neck, but unfortunately no uniformly satisfactory technique has as yet been developed, and most experienced workers still rely on surgery combined with irradiation where the glands are palpably involved. In quite a number of early cases no metastasis occurs, and prophylactic irradiation can be given by means of external applicators for periods up to three weeks. This method has not been employed to any extent at this centre, owing to restricted facilities. A careful system of examination at monthly intervals is adopted and, if glandular enlargement occurs, a block-dissection combined with implantation of radium is carried out. The alternative procedure is implantation of tubes on the same lines as for the primary lesion, but the surgical exposure necessary to implant in all the possible sites of spread is so great that a block-dissection might as well be done.

In a few cases in which the primary growth has resolved, and in which the glands have been too fixed for surgical removal, implantation has been resorted to, with comparatively good results. It is felt, however, that in these cases metastasis must have been limited to the palpably enlarged glands, and at present I would only recommend it in inoperable cases and in cases in which the condition of the patient rendered a very extensive dissection inadvisable. The block-dissections carried out are thorough, and include the removal of the internal jugular vein and the sterno-mastoid. As an onlooker and assistant at this procedure I am convinced that the routine removal of these structures accelerates the operation, gives greater access, and accomplishes a more thorough clearance of both anterior and posterior triangles than any effort to preserve them. When this operation is completed 8–12 tubes, containing about 6 mc. of radium emanation and screened by 0·8 mm. of platinum, are implanted in the wound, concentration being directed usually to the area deep to the parotid and angle of the jaw, and to whichever gland-bearing area is most likely to be affected. The silk threads attached to the tubes are brought out at the lower end of the cervical incision, and act as excellent drains. They are removed in three to four days' time. The primary lesion has invariably been dealt with in the first place.

A number of workers, including most of the French school, advocate the treatment of the lymphatic area before the primary lesion, either by dissection followed by prolonged external irradiation, or by external irradiation alone. They do so on the ground that the presence of radio-active sources in the mouth may have a stimulating effect on distant deposits in the lymphatic zone; it is a widely held theory that irradiation which is effective over a small area only may have a stimulating effect on outlying parts. I can, however, only recall two or three cases in which this seemed probable and other causes may have been operative. From a surgical standpoint it is obviously better to deal first with a source of sepsis, and from a pathological standpoint with what must always be a source of malignant emboli.

Diagnosis.

By far the largest number of cases of carcinoma of the mouth and tongue are seen in men—97 per cent. in my own experience—and the persistence of any form of ulceration in the mouth for more than a week or two in a patient over 30 years of age should arouse a strong suspicion of malignancy. The result of a Wassermann reaction is rapidly obtained with the

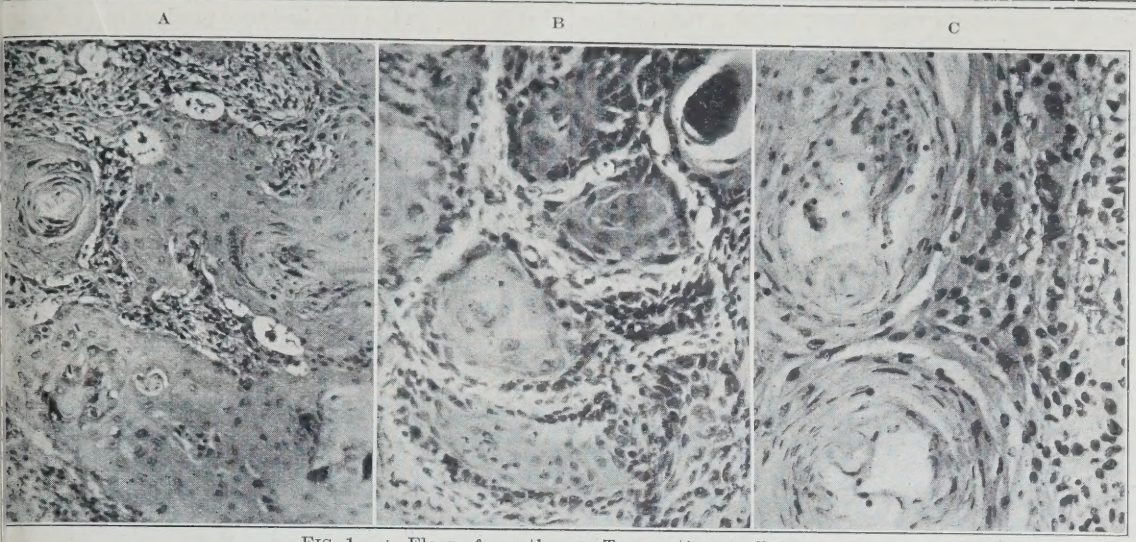

FIG. 1.—A, Floor of mouth. B, Tongue tip. C, Palate.

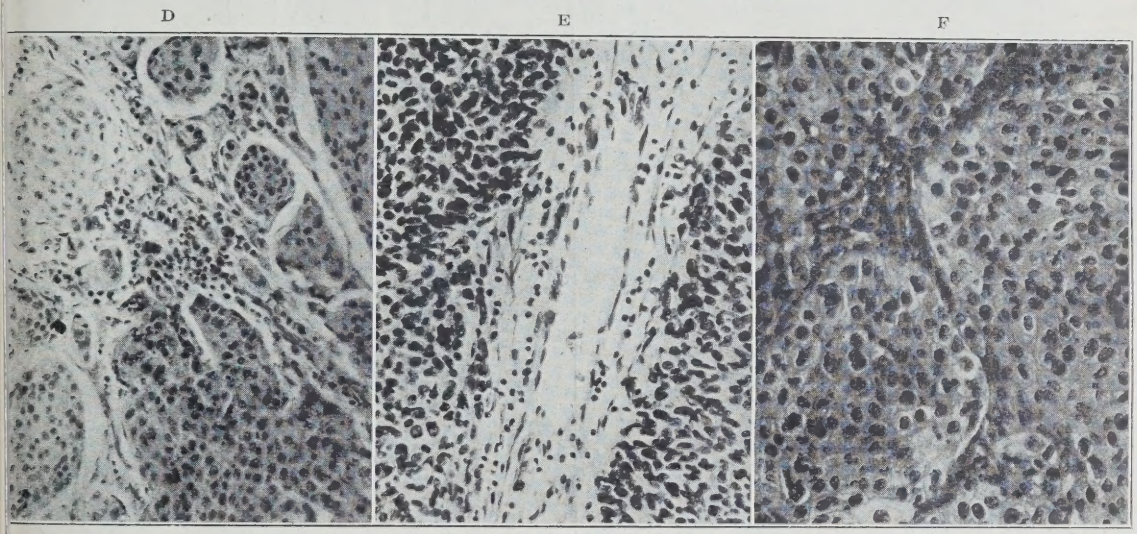

FIG. 2.—D, E, F, Base of tongue.

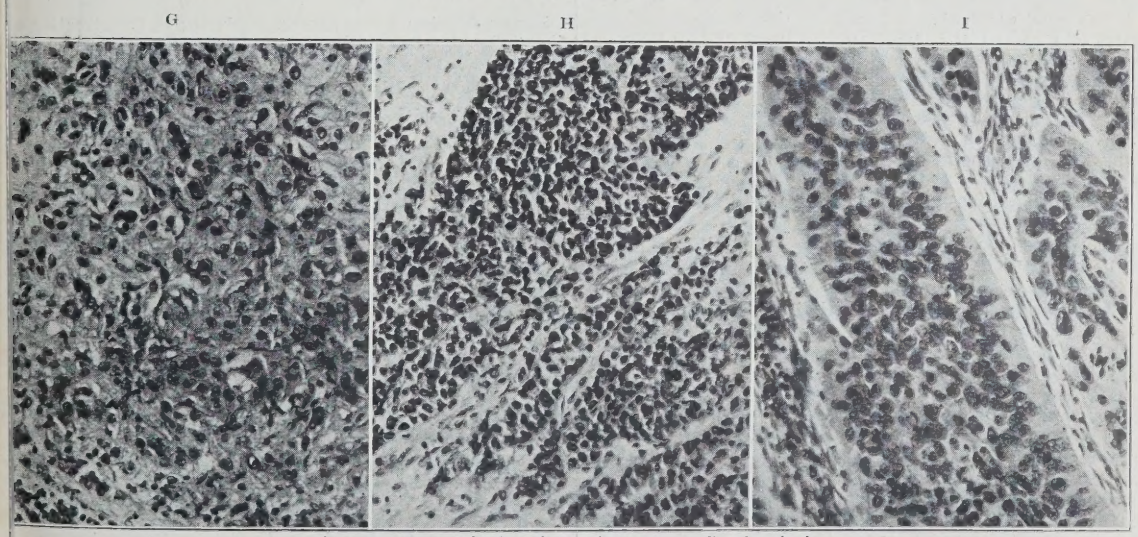

FIG. 3.—G, H, Middle third of tongue. I, Cervix uteri.

Figs. 1, 2, and 3 are microphotographs showing the variability in type of squamous epitheliomata met with in the buccal cavity in different sites. A typical section from a case of carcinoma of the cervix uteri (Fig. 3 I) is included for comparison with those of the base of the tongue. Both are undifferentiated in type and radio-sensitive. In all cases, save that from the cervix, sections were taken from the secondary deposits in the neck.

facilities available in these days, whilst a tuberculous ulcer is usually secondary to a fairly obvious pulmonary lesion. I condemn wholeheartedly the removal of a piece for section as incomplete surgical operations in malignant disease tend both to accelerate local growth and to favour metastasis; very few surgeons would incise a cancer of the breast without proceeding immediately to a radical amputation.

Naturally a surgeon must be absolutely sure of his diagnosis before performing a hemi- or complete glossectomy, but radium treatment is a conservative method which causes little or no impairment of function. To the criticism that one should hesitate to perform block-dissection unless the exact nature of the primary lesion is known, I reply that the majority of patients are elderly and that, unless palpable glands are present, a conservative and expectant attitude is actually adopted. The persistence of palpable glands after the disappearance of the primary lesion is sufficient ground for the surgical operation, and these glands usually afford positive evidence of malignancy. The use of two divergent methods of treatment for the same condition—viz., radium for the primary lesion and surgery plus radium for the lymphatic area—is justified by the following facts. By virtue of its position cancer of the mouth is rarely capable of wide excision. On the other hand, metastasis occurs along a system, so to speak, of pipes and cisterns. Before the walls of this system have been invaded it should be an ideal field for surgical treatment, so long as spread is embolic and not by permeation.

Histology.

Broadly speaking, carcinoma of the mouth and tongue is a squamous epithelioma, and the usual impression given by text-books is that it is well differentiated with an abundance of cell nests and epithelial pearls. Clinically, however, impressive results were obtained, on the primary site, at any rate, in a group of cases in which the lesion was localised at the base of the tongue. From the point of view of accessibility and visibility this is the worst site in the mouth, and it is difficult to suture or implant tubes here. Yet seven out of ten primary lesions resolved, which was much the best percentage figure obtained for any site. As sections from the primary site are not taken only three cases have been examined, the material having been obtained from the glands removed. In each of the three cases sectioned the slides show a highly cellular, undifferentiated type of growth with no cell nests or epithelial pearls, closely resembling carcinoma of the cervix uteri, which is also highly radio-sensitive (Figs. 1, 2, and 3). Ewing's "Neoplastic Diseases"[3] states that "embryonal forms of epithelioma arise in the base of the tongue, tonsil, and pharynx, but their exact structure is undetermined. The cells lack squamous characters and they grow in columns or in distant alveoli." Quick and Cutler[4] have recently drawn attention to a group of 14 cases of intra-oral tumours which they designate "transitional cell carcinoma." Of these 10 were found in the tonsil, 3 in the base of the tongue, and 1 in the cheek. Clinically metastasis was widespread and early, and they were extremely sensitive to irradiation. The highly responsive group at the base of the tongue in my series probably belongs to this category.

The lesions seemed to fall into three groups: (*a*) involving the tip and anterior third; (*b*) arising at the base of the tonsil, tending to involve the middle third of the tongue and spreading to the tonsil and fauces and floor of the mouth; (*c*) involving the base of the tongue.

Of 76 cases in which the tongue was involved and treated 14 were in class (*a*), 52 in (*b*), and 10 in (*c*). Two more cases in class (*a*) had been dealt with surgically elsewhere, the patients being referred for treatment of the metastases. It is of interest to note that in 8 of these 16 cases in class (*a*) there was positive and in 5 cases strongly presumptive evidence of syphilis. Although syphilis is undoubtedly an important ætiological factor in the production of carcinoma of the tongue, clinical evidence suggests that it must in the first instance produce local damage. A positive Wassermann reaction, unless a local lesion is present, does not necessarily indicate that syphilis is the causal or predisposing factor.

The histological types in the different sites were as follows:—

Tongue: Tip and anterior third: well differentiated and highly keratinised type. Base of fauces: indeterminate types—some differentiated, others undifferentiated. Base of tongue: highly cellular and undifferentiated.

Floor of mouth: Highly keratinised.

Palate: Differentiated and undifferentiated.

Cheek and lip: Highly keratinised.

Figs. 1, 2, and 3 show the variations in type and also the resemblance of a typical carcinoma of the cervix uteri to those at the base of the tongue.

FIG. 4.

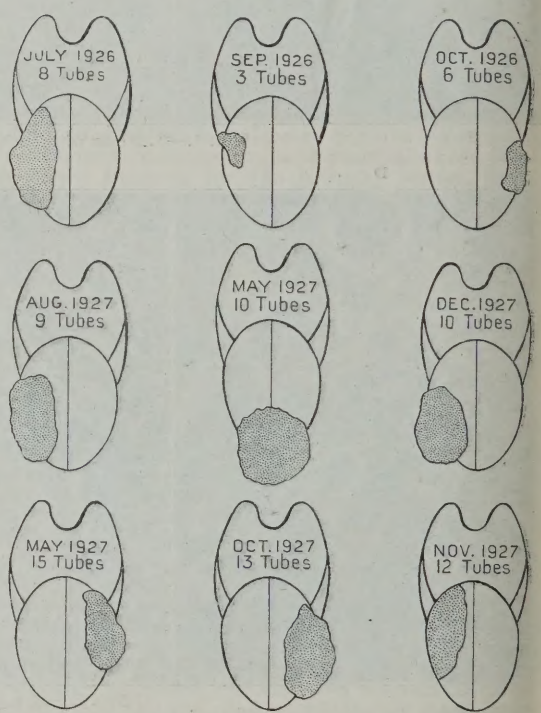

Diagram forming a key to Fig. 5. It shows the situation and extent of the primary lesion in nine cases of carcinoma of the tongue on the dates given. The photographs, taken in March, 1928, show the good functional result as judged by ability to protrude the tongue. There is no sign of local or metastatic disease in any of these cases. The number of tubes implanted gives some idea of the size of the respective primary lesions.

Reaction, Complications, and Sequelæ.

The reaction, if platinum 0·4 to 0·5 mm. is used, is not severe and is hardly noticed by the ordinary type of hospital patient. As a rule, by about the fourteenth day the treatment zone becomes coated with a deposit or adherent exudative membrane, which is best compared with the late fibrinous deposit over the pleura of a patient dead of lobar pneumonia. It is greenish-yellow in colour and is adherent, and yet it is by no means a slough. It usually disappears in about four to six weeks after treatment, when the indurated zone becomes softer, but probably three months elapse before the area treated becomes as supple and soft as the ordinary healthy tissues. Occasionally, probably from faulty distribution of tubes, tissue necrosis occurs, is accompanied by severe pain, and the formation of a depressed ulcer, covered by a tough, adherent, green slough and extremely tender to the touch. There is a surrounding zone of induration and sometimes only experience can decide whether this induration is due to the persistence of the causal factor or to an inflammatory thickening. Some of the

nch school advocate protection of the bony parts, ich are said to be especially prone to necrosis npared with the softer tissues. It is quite a feat endurance to tolerate the presence of what amounts a pin-cushion in the mouth for a week or more. A d mould to the alveoli would increase this dis-nfort, and in my experience is unnecessary. Profuse morrhage has accompanied treatment in two tances, but occasioned no anxiety. It was probably to ulceration into the lingual artery.

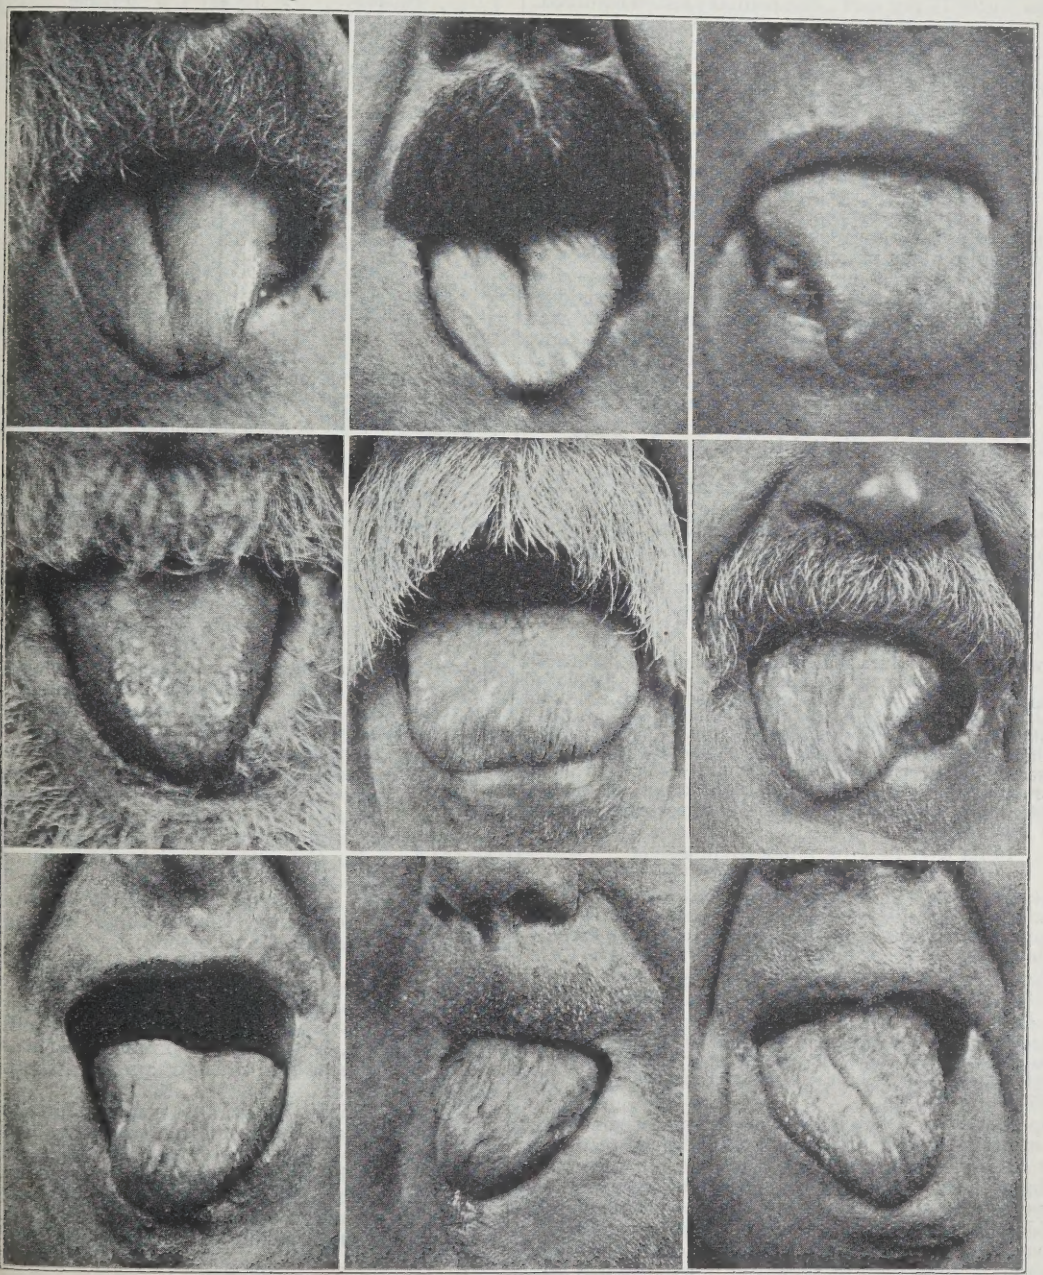
Results.

The results in the primary lesion are appended. here a lesion involved more than one site it was included under the various headings, so that some cases appear more than once.

—	Well.	Total.	Percentage well.
Tongue	34	75	46·66
Fauces and tonsil	10	36	27·77
Floor of mouth	14	42	33·33
Hard and soft palates ..	11	36	30·50
Cheek and lip	11	26	42·0

On the whole this corresponds with the ability to retain tubes, with the exception of the floor of the

FIG. 5.



Photographs taken in March, 1928, showing good functional results. The original site of the growths, and the time at which treatment began, may be seen from Fig. 4, which forms a key to the above photographs. In each case it will be seen that the tongue as a whole is drawn over towards the side of lesion, whilst the tip is turned slightly towards the opposite side.

mouth, where bone is often involved; this constitutes a bad prognostic feature. A modification of the type of tube will probably bring about better results in the palate, fauces, and tonsil. As a rule there is very little tissue here in which to implant tubes and the sutures tend to cut through.

An analysis of the 1926 results showed that 40·8 per cent. of those whose treatments continued for seven or more days were well, compared with 22·8 per cent. of those treated for less than seven days. A minimum treatment of seven days has therefore been the aim in subsequent cases.

The results of treatment can be variously stated. Eighty cases were treated during 1926 and of these 22, or 27·5 per cent., are still free from local or metastatic evidence of disease. At the end of 1926 the percentage had been assessed at 25 per cent. In 31 cases, or 38·75 per cent., the primary lesion resolved. In 29 cases, or 36·25 per cent., there has been no evidence of recurrence at the primary site.

Seventy-four cases were treated during 1927. Twenty-six of these, or 35 per cent., show no signs of local or metastatic disease. In 34 of these, or 45·9 per cent., the primary lesion resolved. Some of the cases will probably resolve later.

Forty-eight cases treated during 1926 and 1927 are at present under observation and have no local or metastatic signs of disease. The main point is that, by means of a fairly uniform technique, or at any rate by the employment of one principle of irradiation—a small unit dose for a comparatively prolonged period of time—it is apparently possible to cure a considerable number of patients suffering from what was clinically undoubted buccal carcinoma. In 43 per cent. of these cases there was a positive histological diagnosis, chiefly obtained from secondary deposits in the neck. In an additional 16·6 per cent. of cases there was a negative Wassermann reaction. The diagnosis was purely clinical in the remaining 40 per cent. of cases.

It is impossible to refer in detail to all the successful cases, and the following one is selected for several reasons. In the first place, surgery was impossible, so that there was no question of an alternative method of treatment, except X rays and lead. Secondly, it was a very advanced case and illustrates what can be done and what may be done more frequently in the future if technique improves and experience ripens.

July 20th, 1926: Duration eight to nine months. Referred by Mr. Geoffrey Jefferson. Tongue fairly mobile, protruded to right. There was an indurated lesion with central ulceration extending from the base of the tonsil to the epiglottis and crossing the middle line, involving practically the whole of the base of the tongue. There were three hard, enlarged glands in the right side of the neck, two in the right submaxillary triangle, and one in the right upper deep cervical group. One gland in the left upper deep cervical group was enlarged.

10 Ra E=1 Pt. 6/10 } inserted in base of
1 Ra E=2 Pt. 6/10 } tongue for nine days.

Sept. 24th: No sign of growth in tongue.
Oct. 20th: Block-dissection by Mr. Jefferson. Sixteen radium emanation tubes of 6 mc. each, screened by Pt. 4/10, were implanted in the wound and left for four days.
Nov. 3rd: Similar procedures on left side.

8 E.T.'s=7 each Pt. 0·8 mm. } being implanted
5 ,, =6 ,, Pt. 0·5 mm. } for three days.

A section from a gland from each side of the neck showed an undifferentiated type of squamous epithelioma. The patient was well in February, 1928, 18 months after first coming under treatment.

The results are admittedly too recent to be claimed as more than apparent cures, but they are results in an inoperable type of case and they confirm the continental experience of Régaud among others, and Evans and Cade [2] in this country. Functionally considered, they are almost perfect, especially in comparison with those of surgery of the tongue. Although a good deal of selection is exercised a large number of the cases claimed as apparent cures are very advanced and absolutely beyond the hope of surgery. If, therefore, radium can effect the disappearance, even for a year, of all clinical signs of the disease it has surely a claim to consideration in th early and operable types of case, especially considerin the poor results from surgery and, in the case of th tongue, the great impairment of function.

Cases marked * developed radium necrosis which later clear up. It is significant that all except one of these cases had mo than one application. Otherwise it is obvious that in by f the greatest number of cases the primary growth resolved aft one treatment.

Future Progress.

(*a*) *The Primary Site.*—I believe with Régaud that a long source of irradiation in a buried tube preferable to a short one, and I suggest that needl employing an active length of 2·5–3 cm. would produ better results in the more advanced types of cas Apart from this I doubt whether there will be ar improvement, except such as experience furnishe in the treatment of this site. Especially for th reason I regard the percentage of apparent cur obtained in the series detailed above as much too lo Probably an attempt is made to treat too many cas with the facilities available.

(*b*) *The Lymphatic Area.*—The results from mo centres are disappointing, but I intend to adopt t method of prolonged external irradiation in the radi sensitive type met with at the base of the tongue. is apparently difficult to obtain a sufficiently inten depth-dose in the more resistant types witho damaging the skin too severely. It may be th comparatively restricted facilities account for the results, and certainly the method has not be sufficiently tried in Manchester.

(*c*) *Visceral Metastases.*—Seeing how much mo difficult it is to deal with the lymphatic region tha with the primary lesion I can hardly conceive th visceral metastases could be treated successfully. Th are, of course, relatively uncommon in this type malignant disease and most frequent in the undiffe entiated types.

I do not think that a long period of irradiation necessarily the only useful method in radiotherap I believe that greater uniformity of results a better results in buccal carcinoma are achieved by but in some other situations, as, for instance, carcinor of the cervix uteri, other factors must be taken in account and on occasion call for a "split" method application.

I wish to acknowledge with thanks the help whi has been freely given by the honorary surgical sta of Ancoats Hospital, Christie Hospital, Manchest Royal Infirmary, and Salford Royal Hospital, in su

rgical work as was necessary in dealing with the mphatic area, and in particular to Mr. W. R. Douglas, o has performed the block-dissections at the stitute. Dr. C. Powell White has kindly allowed s laboratory assistant, Mr. H. Taylor, to prepare e microphotographs which are shown.

CUTE RHEUMATISM IN CHILDHOOD.

By C. J. McSWEENEY, M.B. N.U.I., D.P.H.,
EPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER, CARDIFF.

THE problem of acute rheumatic infection in ldren is one which in recent years has been eiving more and more attention. During 1927 the dical Research Council and the Ministry of Health ve each issued publications which deal very com- hensively with the many aspects of the question. A subcommittee of the British Medical Association s issued two long reports [1] and contemporary dical literature is rich in references to rheumatism childhood. The annual reports of the chief medical cer to the Board of Education have for many years lt specially with the subject of rheumatism, and current issue [2] just published is no exception. at this problem has become a matter of general cern is obvious from the references to rheumatism ch are to be found in the annual reports for 1926 many school medical officers throughout the ntry. There is general agreement that rheumatic ases contracted in childhood are responsible for ery large number of deaths every year. G. A. an [3] and A. P. Thomson [4] say that half of the 00 deaths from heart disease which occurred in gland and Wales in 1924 were of rheumatic origin. ey Coombs [5] is of opinion that all deaths from rt disease under 40 years of age may be ascribed rheumatism. It is very probable that at least 00 deaths occur annually in England and Wales n cardiac disease following upon acute rheumatic ase—a figure exceeded only, in years when influenza ot epidemic, by cancer and tuberculosis. Whilst results of juvenile rheumatism are generally gnised, there is not the same measure of agree- nt concerning the relative significance of various ors in the production of the disease. Thus the lical Research workers [6] found that an unhealthy e of the tonsils was not an essential factor in the luction of juvenile rheumatism and that tonsil- omy was no guarantee of immunity to rheumatism. s important to remember that these findings were d on an investigation which included a large rol series of observations made on non-rheumatic dren. The B.M.A. subcommittee's report, on the r hand, considers the disease as essentially ciated with tonsillar sepsis and alleges that nanent heart trouble never develops after ton- ctomy. The Medical Research Council's inquiry d that dampness was only slightly more frequent he houses of rheumatic children than in those of control series, whereas the B.M.A. report stresses importance of this environmental factor in the ation of the disease. Direct contagion is not ounted as a possible factor by the Medical earch Council workers who produce figures con- nt with the theory of infectivity, but the B.M.A. ommittee definitely regard this factor as being o practical importance. It is clear that any her investigations among rheumatic children ied out with the object of elucidating this aspect he problem must be balanced by a series of observations relating to a similar group of non-rheumatic children.

Rheumatism in Cardiff School-children.

During 1927 a special inquiry was made into the factors associated with rheumatic infection among Cardiff school-children. Cases for investigation were selected from the current departmental records, there being referred for special examination all cases: (1) in which cardiac disease existed or was suspected; (2) suffering from or giving a history of rheumatic manifestations; and (3) whose recent or remote absence from school had been medically certified as due to a rheumatic manifestation. Obviously the first selection included many cases of congenital cardiac disease, habit spasm, functional disorders, &c., but it was considered wise to spread the net as reasonably wide as possible. The result was that out of 400 or 500 children specially gathered in this way some 214 were found to present positive and unequivocal evidence of rheumatic infection.

For the purpose of this inquiry the mere mention by the parent of growing pains was not accepted as evidence of rheumatism. Only definite prolonged or repeated pains in limbs were so regarded. The choreas had been observed and recorded by a medical officer, the heart condition had been detected at school inspection or clinic, rheumatic fevers had been certified by a private practitioner and corroborated by the existing sequelæ. Any case which showed only one factor which in itself was doubtful was excluded from the present survey. Yet it would be very unwise to restrict our conception of rheumatic disorders in childhood to the cases showing unequivocal clinical signs. In every affection all grades of severity are met with, and it is conceivable that some cases of mild rheumatism showing no clinical signs at the moment of examination were excluded from this inquiry. Reference to Table I. will show how few were the manifestations of this infection which came once and not again. One of the most striking, though not unexpected, results of this inquiry is the tendency shown by rheumatism to recur in some form or other.

A control group of children were also examined. These unfortunately were limited as to numbers by a sudden emergency, but it was possible to examine 116 who had no evidence of rheumatism and who had not any affection of the heart. These children were selected at random and were all of school age. In addition to very full inquiries into the personal and family history of both rheumatics and controls their houses were visited by sanitary inspectors who, to avoid bias, were not informed of the association of the houses with this inquiry. Among other things, detailed knowledge was thus obtained as to the extent, nature, and cause of dampness in the houses both of rheumatic and control cases.

General Symptomatology.

The rheumatic manifestations observed were classified under the following heads—viz., Rheumatic Pains, Rheumatic Fever, Chorea, Rheumatic Carditis, Arthritis, Erythema Nodosum, and Other Manifestations. Of the 214 rheumatic children examined 133 had rheumatic pains at some time or other, 65 had rheumatic fever, 129 had rheumatic carditis resulting in permanent valvular disease, 44 had rheumatic carditis which had not at the time of examination led to permanent valvular disease, 9 cases showed erythema nodosum, and 27 cases showed arthritis. A distinction is made throughout this report between permanent valvular disease and other forms of rheumatic cardiac involvement. The latter group relates to cases where definite cardiac mischief is manifested by impairment of the heart's sounds, but where sufficient evidence is not available to show clearly that the lesions are permanent.

Rheumatic Pains.—Apart from cardiac involvement this was by far the commonest rheumatic manifestation shown. Seventy-nine children started their rheumatic troubles in this way and most of the children examined had rheumatic pains at one time or another. The pains were more often experienced in the legs than in the arms and were by no

means related to the joints in all cases. A stiffness of the muscles and joints was very common.

Rheumatic Fever.—Fifty-five children had this form of manifestation at onset and ten others developed it after a definite onset as rheumatic pains or chorea. This manifestation tended to come early in the disease, if at all. It less often followed on a choreic onset than it did an onset associated with rheumatic pains. In Cardiff no child who developed rheumatic fever failed to have a recurrence of rheumatism in some form or another. At least two attacks of rheumatic fever occurred in nine cases showing this manifestation.

Chorea.—Forty-three of the 214 children started rheumatism in this form which differed from all others in being relatively less liable to lead to other manifestations. In over 20 per cent. of the cases with choreic onsets no further rheumatic signs or symptoms developed.

Rheumatic Carditis.—129 children showed permanent valvular disease: 101 as mitral regurgitation, 23 as mitral stenosis, 3 as aortic regurgitation, and 2 as aortic and mitral regurgitation. Included in this group are four children who had well-marked signs of adherent pericardium. It is a fact worth recording that in at least 41 cases the initial diagnosis of rheumatic carditis was made by an assistant school medical officer during the course of routine inspection or at the clinic. It is safe to say that many of these children would never have been ascertained had school medical facilities not been available. Forty-four of the 214 rheumatic children examined showed evidence of the milder type of cardiac involvement (myocarditis, temporary dilatation, &c.). Eight cases started rheumatism in this way, and of these eight four developed permanent valvular lesions.

Arthritis.—Only ten children showed this symptom at onset, but 17 others developed arthritis during the course of rheumatic infection. Arthritis was usually preceded by periods of pain and stiffness in the joints. Of itself arthritis did not seem to be a manifestation prone to lead to cardiac involvement.

Erythema Nodosum.—This interesting manifestation occurred in three cases as a form of rheumatic onset. In six other cases it developed during the course of the disease.

Other Manifestations.—Twenty-three cases of definite rheumatism (22 involving the heart valves permanently) began without any distinct onset. It may be mentioned that in the search for a possible origin of these insidious cases histories of even sore-throat were generally lacking. The 22 cases were not congenital cardiacs; in every instance the lesions were left-sided and unaccompanied by the physical signs both locally and generally which are characteristic of congenital heart disease.

TABLE I.—*Type of Onset and its Relation to Subsequent Manifestations.*

Cases.	Mode of onset.	Subsequent manifestations. Heart symp.	Rheum. fever.	Rheum. pains.	Chorea.	Eryth. nod.	Other definite symptoms.	Permanent valv. disease.	Total additional manifestations.	Per cent. permanent heart disease.	No manifestations except onset.
8	Heart symp.	3	—	1	1	—	—	4	9	50·0	—
55	Rheum. fever.	6	9	23	11	1	8	41	99	74·5	—
79	Rheum. pains.	16	8	28	8	4	9	41	114	54·4	5
43	Chorea.	7	2	17	8	1	—	17	52	39·5	10
3	Eryth. nod.	1	—	3	—	—	—	1	5	33·3	1
3	Other definite symp.	5	—	4	—	—	2	3	14	100·0	—
23	Indefinite symp.	1	—	6	2	—	—	22	31	95·5	—
214	Totals ..	39	19	82	30	6	19	129	324	60·2	16

Total manifestations per case = 2·5.

Table I. shows that onsets as rheumatic pains, rheumatic fever, and chorea were by far the most common. Next came the cases of quiet origin. The remaining cases which started with heart symptoms, erythema nodosum, &c., are relatively few. The last column in this table shows that out of the 214 cases only 16 had a single manifestation. Ten of these 16 cases were choreas, 5 were cases of rheumatic pains, and one a case of erythema nodosum. The liability of every form of onset to involve the heart is also brought out in this table. Rheumatic fever may be taken as the manifestation most prone to do this; a choreic onset would not seem at all so prone to lead to heart involvement as an onset in the form of rheumatic fever.

Age at Onset.

In 186 of the 214 cases it was possible to ascertain the age at onset of rheumatism. It was found that in 174 children (93 per cent.) it had commenced at school age as usually observed elsewhere. (Table II.)

TABLE II.

Age at Onset of Rheumatism at—

2 years	1	7 years	27	12 years	1
3 „	3	8 „	19	13 „	—
4 „	8	9 „	20	Uncertain ..	2
5 „	25	10 „	29		
6 „	25	11 „	16	Total ..	21

School age (commencing at 5 years) 174 out of 18 known cases = 93 per cent.

Season of Onset.

In 152 cases the season at which rheumatism developed was capable of being ascertained (Table III.)

TABLE III.

Season of Onset (all Rheumatic Manifestations).

	Nos.	Approx. per cent.
Summer	45	30
Autumn	17	11
Winter	59	39
Spring	31	20
Total	152	100

It is impossible from the small numbers investigated to draw any inference as to the effect of season. R. Miller says that there is a definite seasonal incidence in England between October and March, and the Medical Research report [6] suggests that the peaks in the acute rheumatic fever curve are in February and November. The Cardiff figures tend to support these views—almost 60 per cent. of cases investigated began between October and March, but if the choreic onsets are excluded the tendency of rheumatism to develop in the cold, wet months is a little more obvious. When the seasonal onset of chorea alone is considered it is interesting to find that there is more likelihood of a child developing this manifestation towards the end of a school term.

Throat Conditions and Acute Rheumatism.

The influence of throat conditions on the acute rheumatic infection of 214 Cardiff children was investigated in this inquiry and at the same time a control group of 116 non-rheumatic children were examined and subjected to the same standards.

(*a*) *Size of Tonsil.*—To say what is or what is not a healthy tonsil is a very much more difficult task than to record whether or not the tonsil is of normal size, slightly enlarged, moderately enlarged or very much enlarged. On the assumption that the size of the tonsil, in the absence of acute inflammation, is a reliable indication as to the health of the organ, a careful note of the size of the tonsil was made in each case. When the tonsils had been removed this fact was also noted and the effect (if any) of the removal upon rheumatism investigated. (Table IV.)

TABLE IV.—*Size of Tonsil.*

Tonsils.	Rheumatics. Numbers and per cent.	Controls. Numbers and per cent.
Normal	74 (40·8)	54 (46·3)
Slightly enlarged ..	43 (23·7)	31 (26·7)
Moderately enlarged ..	30 (16·5)	13 (11·2)
Enlarged	17 (9·3)	10 (8·6)
Removed	17 (9·3)	8 (6·9)
No remark	33 —	— —
Totals	214 (99·6)	116 (99·7)

There is no significant difference between the two groups. If enlargement is to be taken as the expression of past infection it is clear that the Cardiff figures do not support the conclusion of the B.M.A. subcommittee,[1] who claim that the relation between rheumatism and tonsillar infection is a very close one.

(*b*) *Incidence of Sore-throat.*—Sore-throats were classified as occurring "frequently," "occasionally," "very rarely

ace only," and "never." The same system was adopted h the control group of children. (Table V.)

TABLE V.—*Incidence of Sore-throats.*

Sore-throat.	Rheumatics. Numbers and per cent.	Controls. Numbers and per cent.
ever	129 (60·2)	82 (70·6)
nce only	7 (3·7)	3 (2·5)
ery rare	9 (4·1)	3 (2·5)
ccasional	36 (16·8)	15 (12·8)
requent	33 (15·4)	13 (11·2)
Totals	214 (100·2)	116 (99·6)

ere again there is no significant difference in the matic and control series in any one group. All that can aid is that there is a definite tendency for sore-throats e a little more frequent among the rheumatic than the rol groups. The association between enlargement of il and sore-throat with rheumatism which has long been is not clearly borne out by the Cardiff figures.

Influence of Tonsillectomy on Rheumatism.

triking differences of opinion exist as to the value onsillectomy in the prevention and treatment of matic diseases in children.

. Lawrence,[7] after a detailed analysis of 85 children, rved for three and a half years after their tonsils were ved, considers that tonsillectomy is the most important sure at present available for the prevention of acute matic fever and the allied rheumatic manifestations, e A. P. Thomson [8] says definitely: "The value of early plete tonsillectomy in the prevention of rheumatic t disease is established." On the other hand, the ical Research workers consider that neither cutting nor leation is any guarantee of immunity to rheumatism. ing regard to the advocacy of tonsillectomy for any every rheumatic manifestation it would seem that e is need for caution until this phase of the rheumatic lem is further explored.

regards tonsillectomy in the treatment of rheumatism, t and Osman [9] have given figures which show that the ation definitely increases the risk of rheumatic recurrence, they find that the risk is much more when the operation ne after a later attack than the first. Miller,[1] whose is supported by Poynton, Paterson, and Spence,[10] ests that post-operative rheumatism is in the form of ea in 60–70 per cent. of cases, and discounts the possi- y of graver manifestations occurring after operation. rman and Wilson,[11] reviewing the recurrences of matism occurring within three years of operation on ls, gives a figure so high as 75 per cent.

the Cardiff series 17 rheumatic children had had r tonsils removed at some time or other. In he removal antedated the first rheumatic mani- tation. In 5 the removal post-dated the onset, but not prevent further rheumatic manifestations, gh it may have modified those. It is only fair to that as against the 17 tonsillectomised children developed rheumatism in spite of operation e were 3759 children similarly dealt with at the nose, and throat clinic between 1917 and 1926 , so far as is known, remained free from rheumatism.

Tonsillectomy Before Onset of Rheumatism.—Most of cases developed the first sign of rheumatism at vals of from 2 weeks to 18 months after removal:—

3 within 2 weeks 1 „ 1 month 2 „ 3 months	Five of the six developed rheumatism in the form of chorea.
2 within 4 months 2 „ 12 „ 1 „ 18 „ 2 at remote periods	None of these developed chorea.

analysis of the ten cases which showed rheumatic festations within 18 months of removal reveals that:—

f the 10 had chorea (50 per cent. as compared with 6·7 per cent. in the much larger Medical Research series).
ad permanent valvular disease.
ad the milder type of cardiac involvement.
ad erythema nodosum.
ad rheumatic pains.

fact worth emphasising is that fully half the cases loped rheumatism in the form of chorea and these the earliest cases to manifest rheumatism after removal. of the five children whose chorea followed hard on tonsillectomy only one subsequently developed permanent valvular disease, whereas of the 38 cases who developed chorea without having the tonsils removed as many as 16 subsequently developed permanent valvular disease. It would be rash to generalise, however, on evidence so slender as this.

(2) *Tonsillectomy after First Rheumatic Manifestation.*—Of these cases, 5 in number, 3 had chorea (developed after removal in 2 cases), 2 had permanent valvular disease, 1 had minor heart symptoms, and 4 had rheumatic pains subsequent to removal.

To draw any general deductions as to the influence of tonsillectomy on the origin and development of rheumatism from so small a series would be fallacious in the extreme. The conclusions of the Medical Research Council workers are, however, confirmed by the results obtained from investigating a smaller series in Cardiff.

Infectivity of Rheumatism.

661 Cardiff children (sisters and brothers of rheumatics) were exposed to rheumatic infection by living in the same house. Fifty-one of these were affected (7·7 per cent. case-incidence).

It will be noted that the contact case-incidence of rheumatism is not smaller than that of such notifiable diseases as anterior poliomyelitis and cerebro-spinal fever. Aycock [12] expresses the probability of infection with certain diseases in the following rough numerical fashion: "Of susceptible children exposed to measles 1 out of 1 develops the disease; to diphtheria 1 out of 10 develops the disease and 9 out of 10 develop subclinical immunity; to poliomyelitis 1 out of 100 develops the disease and 99 out of 100 develop subclinical immunity or immunity from abortive attacks." If, therefore, rheumatism were an infection of the same order as poliomyelitis multiple cases in families would be scarce.

It must also be borne in mind that while the Cardiff figures relate entirely to school-children contacts, they were not necessarily bedfellows of the rheumatic children. The possibility of transmission of infection, which St. Lawrence [13] speaks about, was very much greater in the London series,[6] where 382 persons *were sleeping in the same rooms* as 192 children under treatment for rheumatism, than among the Cardiff children, 661 of whom were exposed *to infection by living in the same house.*

Fitness for Ordinary Occupations.

142 of the 214 children examined were found unfit by reason of the consequences of rheumatic infection to follow ordinary occupations in after life—a percentage of 66. The employment of such of these who will survive will have to be chosen with great care and circumspection. Manual work of a laborious character will always be contra-indicated.

Social Factors and Acute Rheumatism.

The social factors including cleanliness, clothing, and maternal care were thoroughly investigated in both the rheumatic and control series. No significant differences were noted. The Cardiff findings in this respect are in agreement with those of Thomson in Birmingham, Hutchinson in London, Morrison in Bristol, and Coates and Thomas in Bath. (Table VI.)

TABLE VI.—*Housing Factors in Relation to Acute Rheumatism.*

	Rheumatics.	Controls.
Number of houses ..	.. 201	106
„ families	.. 298	161
Families per house..	.. 1·48	1·51
Rooms per family ..	.. 3·78	3·53
Total occupants—	.. 1482	769
Over 10 years ..	.. 1088	529
Under „ ..	.. 394	240
Occupants per house	.. 7·37	7·25
„ „ room	.. 1·30	1·31

This table shows that rheumatic children, as far as overcrowding is concerned, live pretty well under the same conditions as the children of the control series. The conditions as to tenancies are also very similar in the two groups; 55·7 per cent. of rheumatics live in singly tenanted houses as against 56·6 per cent. of controls. It can therefore be inferred that overcrowding in the home has little influence on the onset of rheumatism.

But there still remains the question of the influence of overcrowding on the course of rheumatism. Rheumatic children were found to be living under overcrowded conditions in 14 instances, as judged by the Registrar-General's

standard of more than two persons per room, and 13 of these children showed evidences of cardiac involvement. This result is at least suggestive that overcrowding in the home may have an unfavourable influence on the course of a rheumatic infection. If there is any truth in the theory of rheumatic infectivity one would expect to find a higher incidence of rheumatism amongst susceptible persons in such houses than in houses not overcrowded. Investigations showed that of 52 susceptible children exposed to infection when living under overcrowded conditions five contracted acute rheumatism, giving a contact case-incidence of 9·6 per cent. as compared with the general figure of 7·7 per cent.

Environmental factors—e.g., type of district, type, age, state of repair, aspect, cleanliness, and amount of exposure of house were investigated in detail for the two series, but no significant differences were noted.

Dampness in Houses.

Each house was carefully examined for any form of dampness by the sanitary inspectors. The houses of rheumatics examined were in all cases those in which the patients were living at the time when the onset of rheumatism was alleged to have occurred. Table VII. shows that a slightly higher percentage of the rheumatics lived in damp houses.

TABLE VII.

Series.	Houses examined for dampness.	Dampness detected.	Percentage damp.
Rheumatic	201	87	43·2
Control	108	41	37·9

This table relates to dampness of any form, however slight, and it should be noted that one possible fallacy in these figures is that the returns relate to dampness found in 1927, whereas in most cases rheumatism developed some years ago when the house may or may not have been damp. Some of the houses found not damp to-day may have been quite damp at the time when the child developed rheumatism, and vice versa. With this possibility of error in mind it is obvious that any differences found in the two series must be very striking to be considered significant. The difference of 5·3 per cent. shown cannot therefore be taken as evidence in support of the theory that "living in damp dwellings is a powerful predisposing factor" [1] in the development of rheumatism.

An analysis of the site of the dampness present in the houses of each series is set out in Table VIII.

TABLE VIII.—*Site of Dampness.*

Site of dampness.	Rheumatics.	Controls.
	Numbers and per cent.	Numbers and per cent.
Ground floor	43 (21·3)	13 (12·0)
Bedrooms only ..	26 (12·9)	17 (15·7)
Both	18 (8·9)	11 (10·1)
Total damp	87 (43·1)	41 (37·8)

It will be seen that any excess in the incidence of dampness amongst the rheumatic group was probably in the form of ground floor dampness. Investigation showed that this was due to the fact that rheumatics tended to live in the older type of house property which had not a damp-proof course. It is clear, however, that there is not sufficient evidence revealed by the house analyses carried out in this inquiry to justify the conclusion that damp houses of themselves play any notable part in the production of juvenile rheumatism.

A comparison may be made here between the Cardiff results and the St. Thomas's Hospital data of the Medical Research Council's report on Social Conditions and Acute Rheumatism. Table IX. gives the percentage (with standard deviation) of houses found damp classified according to type of dampness.

The figures are not significantly different. Although the houses concerned are probably similar in London and Cardiff, the districts are no doubt very dissimilar. Rather less than 6 per cent. of each group in Cardiff were found to live in congested districts and the city is devoid of slums in the true sense of the word.

TABLE IX.—*Description of Dampness.*

Description of dampness.	Rheumatics.		Controls.	
	M.R.C.	Cardiff.	M.R.C.	Cardiff
Rising damp (ground floor only)	22·0 (±2·1)	21·3 (±2·3)	18·0 (±3·8)	12·0 (±2·8
Defective roof, gutters, ceiling (bedroom only)	13·8 (±1·7)	12·9 (±2·1)	11·0 (±3·1)	15·7 (±2·9
Rising damp and defects of roof.. ..	4·0 (±1·0)	8·9 (±1·9)	4·0 (±2·0)	10·1 (±2·6
All forms of dampness..	39·8 (±2·4)	43·1 (±3·5)	33·0 (±4·7)	37·8 (±4·6

Even although living in a damp house would see not to have any influence on its onset, there st remains the question as to what part of such a environmental factor may play in the course of rheumatic infection. Does living in damp houses with the severer type of rheumatic manifestation A few facts which came to light in investigating t Cardiff cases may be worth recording.

1. The four cases of adherent pericardium (prognos grave in all) did not live in damp houses.

2. Of the 23 cases of mitral stenosis seven only lived damp houses.

3. The five cases with either aortic or aortic and mitr lesions all lived in houses that were not damp.

4. Of 124 houses investigated in respect of 129 childr found to have permanent valvular disease 53 were fou to be damp (42·7 per cent.) as compared with a dampne incidence of 43·2 per cent. for all rheumatics. In abo half the cases of valvular disease who lived in damp hous the dampness was of the ground floor variety. It cann be adduced from these figures that living in damp hous tends to produce a more serious type of rheumatic lesi than living in a dry house.

Soil and Elevation.

It was found that rheumatic children live on lo lying ground usually with a subsoil of estuarine m or clay, whereas the control children were different distributed throughout the city and were much mo frequently found to live on the better type of subs available at higher elevations. The results indica that there may be more than a casual relationsh between soil and elevation on the one hand a rheumatism on the other.

TABLE X.—*Proximity to Water.*

Series.	0–50 yards. No. and per cent.	50–100 yards. No. and per cent.	100–200 yards. No. and per cent.	200–44 yards No. an per cen
Rheumatics ..	14 (6·9)	12 (5·9)	12 (5·9)	12 (5·9
Controls	6 (5·6)	8 (7·5)	3 (2·6)	1 (0·9

There did not seem to be any close relation betwe proximity to water and development of rheumatis A slightly higher percentage of rheumatics were found live within quarter of a mile of waterways or channels, t the increase is chiefly due to children living more th 100 yards distant from water. Bearing in mind the locati of most working-class dwellings in Cardiff this slight differer in figures must be discounted. If living within 100 yards water were a predisposing factor in the development rheumatism then indeed the incidence of rheumatic affectio in Cardiff school-children ought to be much higher.

Summary of Findings.

1. No significant differences as to size of tons or frequency of sore-throats were found to exist wh a series of observations on rheumatic children w compared with a series of observations on a simi group of non-rheumatic children.

2. Chorea, permanent heart disease, and oth rheumatic manifestations were found to have de loped in several cases after tonsillectomy had be performed.

3. Some slight evidence was found in this inqu in support of the theory of infectivity of rheumatis

4. Overcrowding did not seem to predispose to t onset of rheumatism, but 13 of the 14 rheuma

dren found living under overcrowded conditions wed evidence of cardiac involvement.
. The incidence of dampness in the houses of rheumatic children was not significantly higher n in the houses of 108 non-rheumatic children.
. Ground floor dampness was found to exist more n in the houses of rheumatics (which, as a rule, e older houses) than in those occupied by the trols, but this did not seem to produce a tendency ards any particular type of rheumatic onset.
. A general dampness of the house was more often ociated with the onset of rheumatic pains than er types of onset, but the differences were not ificant.
. Dampness of houses, of whatever distribution, not appear to predispose to the onset of chorea in erence to any other type of onset.
. Living in damp houses did not predispose cially to rheumatic fever or to cardiac involvement.

is difficult to reconcile Cardiff experiences with the ngs of the B.M.A. subcommittee, which considers that lisease in industrial towns is essentially one of children g in damp rooms. Obviously any figure for dampness ne houses of rheumatics, however high, is of itself not ficant unless a comparative figure for a control group ouses relating to a suitable series of non-rheumatic ren is placed beside it.

). No close relation was found to exist between imity to water and the development of matism.

must express my thanks to Dr. Ralph M. F. Picken, ical officer of health, Cardiff, at whose request foregoing investigation was undertaken, for ly permitting me to publish these results.

Clinical and Laboratory Notes.

CASE OF ECLAMPSIA TREATED WITH SPINAL ANÆSTHESIA.*

BY R. H. PARAMORE, F.R.C.S. ENG.,

GYNÆCOLOGICAL SURGEON, HOSPITAL OF ST. CROSS, RUGBY.

I the following case spinal anæsthesia was used st the mechanistic conception of eclampsia. If lisease be due to a too great compression of the and kidneys, whereby a capillary obstruction e blood flow through these organs occurs, then a ure calculated to reduce the tonicity of the minal walls and thoracic diaphragm should e or even cure the patient. Chloroform was to stop the fits and to permit the puncture; and sistent lateral position and complete starvation e early after-treatment were stringently insisted

married woman of 23 was admitted to hospital on 24th, 1927, at 11.30 P.M. She was well developed, and had had a child a year ago. She was seven months pregnant. A month ago her husband was called up to serve in China, and she had to give up her home and come into Rugby. This thoroughly upset her. Three weeks before admission puffiness of the face and hands had been noticed, and she complained of headaches. On the night of admission she was having supper as usual, and thinking her child was crying, left the table and went upstairs. The next thing that happened was that the people below heard a noise as of some one falling. They found the woman on the floor in a fit. A doctor was sent for, who advised admission to hospital. Before admission she had had two fits; her tongue was bitten and two teeth broken. She had a succession of fits after admission without recovering consciousness. The pulse was 104, full and bounding; respirations, 24; temperature, 98° F. At 12·30 chloroform was administered, and I saw her soon after.

By catheter, 2 oz. of highly albuminous urine came away. The lumbar region was exposed and painted with iodine; a needle inserted into the dura; cerebro-spinal fluid, apparently under normal pressure, in small quantity, was allowed to escape; and 1·5 c.cm. of a 5 per cent. solution of tropacocaine (Allen and Hanburys, Ltd.) was injected. The needle was withdrawn, the wound dressed, the chloroform stopped, and instructions given to maintain the patient on her (left) side and report at once if any further fit occurred. Nothing else was done.

I descended with the resident medical officer to his room to await events. At about half-past two we visited the patient, no report having been received. I found her in a semi-drowsy state—she had had no further fit, but had been rather restless, throwing her arms and legs about. In my presence she vomited and defæcated simultaneously, being still on her side; the visceral action was spontaneous. Her condition seemed much improved. Instructions were given that she should be maintained on her side and given nothing but water, when she could take it.

At 11 A.M. the report was favourable—the patient had had a quiet night; a further motion had been passed; she was quite rational. The blood pressure was given as 143 systolic and 100 diastolic. At 9 P.M. it was 120/80; the patient complained of headache. The total urine passed on that day (Feb. 25th) was 24 oz. From this time the further progress of the case was uneventful—except that the amount of urine passed did not exceed 30 oz. for the first four days; that the blood pressure became again raised (on Feb. 28th it was 150/110); that the fœtal heart, heard on March 1st, was not heard on March 2nd, and that the patient miscarried on March 4th. With the death of the child the amount of urine increased and the blood pressure fell; after delivery both conditions improved still more. The urine increased to over 60 oz. on some days, and the albumin, on March 8th, had gone. The patient was discharged on March 19th apparently quite well.

The method here described has not been tried in any other case, for no other up to the time of publication was available.

* eing part of a paper entitled Eclampsia and Its Treatment: xperience with Spinal Anæsthesia in One Case, and read the Obstetrical and Gynæcological Section of the Royal y of Medicine on April 20th.

NOTE ON THE TREATMENT OF TOXIC PERI-ARTHRITIS.

BY L. C. DUNDAS IRVINE, B.A. CAMB., M.R.C.S. ENG.

IT is recognised that a chronic, painful inflammation of the tissues round the joints, proceeding if unchecked to deformity and loss of power, is associated with the absorption of toxins of bacterial origin.

A great many cases in the past have responded fairly satisfactorily to removal of the teeth, but far more have gone on unchanged. It may, therefore, be worth while to place on record a series of cases, the earliest of which dates back to 1924, in which there have been marked improvement from the following course of treatment: (1) An attempt was made to deal with the bacteria themselves by vaccine therapy. (2) By a carefully regulated diet, I tried to alter the nature of the bowel contents so as to encourage the growth of the lactic acid bacillus. (3) The injured tissues were treated locally by high frequency, massage, and poultices composed of mud imported from Pistany, in Czecho-Slovakia. (4) Every possible attempt was made to increase the elimination of toxic products from the body by prescribing large quantities of fluid to be drunk

daily, and particularly by giving atoquinol (Ciba) [1] in fairly large doses for a long period. It was given in periods of three days on and three days off, always with large draughts of water, and sometimes with bicarbonate of soda (in doses of grs. 5) where the patient complained that the tablets alone caused indigestion.

Eighty-seven cases have been treated. At the first examination I devoted my attention to discovering the site of the toxic absorption. In 74 per cent. of the cases this was associated with infection of the large bowel by a pathogenic *Bacillus coli communis* and a pathogenic *Streptococcus fœcalis*. In 8 per cent. the originating bacteria were found in the tonsils; in 7 per cent. they were in the teeth, mouth, and throat; in 7 per cent. in the nose and maxillary antrum or accessory sinuses. Two of the cases were gonococcal, and in two no source of bacterial infection could be discovered.

The autogenous vaccine was usually given in 16 doses, starting with five million *B. coli communis*, with five million streptococci, or 25 million staphylococci, and increasing by steps up to 200 million in *B. coli* and streptococci respectively, and to 400 million in staphylococci. The injections were given, as a general rule, twice a week and were not followed by any severe reaction. There was sometimes an increase in the joint pains, sometimes a little general malaise. As the doses increased in size, the interval between them was lengthened until the last four were given, as a rule, at intervals of ten days.

While this was going on they were put on a diet which consisted of what one might call farm produce—milk, eggs, butter, cheese, fruit, vegetables, salads, the last with lemon-juice instead of vinegar. Fish and chicken were added if the diet was found to be too low, but no red meat, and if possible no alcohol. The fluid taken was made to exceed 2 quarts a day, taken at regular intervals, barley-water, orange-juice, or lemon-juice being the prevailing forms. Some of the cases were given milk soured by the *Bacillus bulgaricus*, and, as I have said, about six tablets of atoquinol were given each day for three days and then omitted for a similar period, and repeated. Aperients were given when necessary, but every attempt was made to substitute fruit for purgatives.

The inflamed joints, if very painful and swollen, were either poulticed with Pistany mud or, in the case of the hands and feet, actually plunged into a basin of the mud. The skin had to be plentifully smeared with vaseline to prevent the mud from adhering and burning. In one or two cases slight burns did occur which gave trouble and were a long time in healing, but eventually cleared up satisfactorily. It was found that the mud reduced the tenderness and swelling of the joints to a remarkable degree, and made it possible to manipulate them at a very much earlier stage in the treatment. Passive movement and massage was begun as soon as it could be done without pain, and it was very striking how rapidly the most severely deformed hands responded to this treatment and resumed their normal shape. Where the joints were very stiff, high-frequency was added to the massage and manipulation, and it was found that movements which had not been possible for months, or even years, were regained. The local treatment was given daily whenever possible, though at the beginning many of the cases could not stand more than twice a week, as the skin over the inflamed tissues was apt to become sore. Towards the close of the treatment many of the cases were given artificial light with very obvious beneficial results in the improvement of the general bodily tone.

[1] There was at one time a good deal of hostile feeling against this preparation after reports of cases where fatal cirrhosis trouble followed on its long-continued administration. In the course of four years, however, I have seen no case in which it gave rise to any untoward symptoms, and even a patient with an enlarged liver due to taking too much alcohol stood the treatment satisfactorily.

Of the 87 patients treated, 53 were able to resum their work without pain and have, so far, had r return; 22 were able to go back to work, but had relapse, which yielded to a further course of treatmen Of these relapsed cases, three came back for a thi course of treatment, and of the three one is having fourth course. In each of the latter cases the patie has been sufficiently relieved from pain and improv in general health to present himself, of his own accor for further treatment. Of the remaining 12, six ha proved unsatisfactory; of these six, two were tho in whom no source of infection could be found, a the remaining six have too recently completed the treatment for any definite result to be claimed.

No special discovery and no new method of trea ment is claimed for this series of cases. It is probab only the combination of the various methods treatment and the thoroughness with which th have been carried out which has led to such sati factory results. The total number treated is, course, small, and it may well be that when this h been considerably increased the percentage of tho who returned to their work will not be found to so high. But it is not unsatisfactory that so ma patients suffering from a crippling and painful disea should have improved enough to resume their wor

A NON-IRRITATING SILVER-ARSENIC COMPOUND.

By Harold O. Long, M.R.C.S. Eng.

The extreme toxicity to the tissues of preparatio of silver and arsenic is well known; because th cannot be introduced intramuscularly or subcutan ously intravenous therapy has been the one meth of exhibiting them. While the intravenous meth of administration is the ideal one, if conditions a satisfactory, it has disadvantages and distinct limit tions in certain circumstances, first on account the difficulty of finding a vein in some patients; an secondly, because of the great local reaction in t surrounding tissues if the merest drop of some co pounds escapes the lumen of the vein. This latt accident may not only produce sloughing of the tissu but it may completely damage the area for futu intravenous injections. Worrying experiences of th kind, both personal and reported by other prac tioners, led me to seek a substitute for the preparatio hitherto used in the treatment of disseminat sclerosis and other nervous diseases of obscure orig Arseno-argenticum (May and Baker) is an excelle compound with which some highly satisfactory resu have been obtained over a number of years apparently controlling the manifestation of t disease and also in greatly improving sympton Doses of 0·05 g. to 0·3 g. (increasing by 0·05 g.) ha been given intravenously in six doses at weekly fortnightly intervals each year, the patient taki courses of arsenic by the mouth periodically duri the rest of the year. The risk of continuing treatm is very great as some veins become almost impossi to find, especially if a single slight accident h produced thickening and inflammation in the ar For this reason a new preparation for intramuscu injection, metarseno-argenticum (M.A.A.) has be especially prepared for the writer by Messrs. May a Baker, Ltd. It contains approximately the sa percentage of silver and arsenic, and has been used the same dosage and given at similar intervals to t intravenous product arseno-argenticum. It has be extensively used on mice and rabbits with no appar irritation of the tissues. The first injection given a human being was made by the writer into his o abdominal wall. A solution of 0·05 g. in 2 c.cm. sterile distilled water was used and about 0·5 c.c injected. There was a little pain but no inflammati and after a week there was no trace of the site inoculation. The next injection was given to

ent who had had arseno-argenticum injections for years, and had come to dread them very much on unt of the extreme difficulty of administration. first dose was again a solution of 0·05 g. in cm. of water, and 0·75 c.cm. was given in the eal region. There was no pain or subsequent omfort. The injections were then given at kly intervals in the following way :—

0·05 g. in 2 c.cm. s.d.w.	No reaction.
0·1 g. " "	"
0·2 g. in 3 c.cm. s.d.w.	Some thickening. Severe pain down the leg for a few moments.
0·2 g. " "	No reaction.
0·3 g. in 5 c.cm. s.d.w.	No serious reaction; slight soreness and irritation for three or four days.
0·3 g. " "	Painless and produced no subsequent trouble.

s.d.w. = Sterile distilled water.

he next patient had most difficult veins and was ghted at being spared the previous intravenous tment. The injections were given into the gluteal on, and the record is as follows :—

perimental dose of 0·05 g. in 2 c.cm. water, of which c.cm. was given, produced no general or local ion.

0·05 g. in 2 c.cm. s.d.w.	No reaction.
0·1 g. " "	A little solution leaked out of the syringe into the subcutaneous tissues, and produced, momentarily, considerable pain and smarting, and some slight redness later.
0·1 g. in 3 c.cm. s.d.w.	The greater dilution produced no pain or reaction.
0·2 g. in 5 c.cm. s.d.w.	These all produced slight pain on injection, but no subsequent trouble at all, except for a little thickening for a few days.
0·2 g. " "	
0·3 g. in 8 c.cm. s.d.w.	

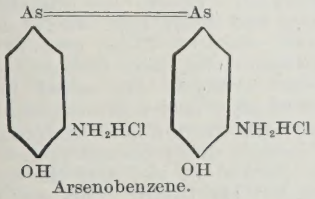
together, therefore, 15 injections have been given i no bad reaction at all.

ne product, therefore, seems to be safe enough for ner use, and the relief to the patient and operator emendous.

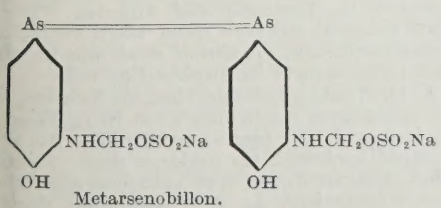
he two products are almost identical in silver and nic content, thus :—

	Silver. Per cent.	Arsenic. Per cent.
eno-argenticum contains	13 to 15	21 to 24
tarseno-argenticum "	14	16 to 17

o satisfactory formulæ can be assigned to these r coördination products of arseno-bases. Metrobillon is a formaldehyde bisulphite derivative senobenzene, the structural relationship of these s being shown by the following formulæ :—



Arsenobenzene.



Metarsenobillon.

tarseno-argenticum is obtainable from the manufacrers, Messrs. May and Baker, Battersea, to whom, and especially to Dr. A. J. Ewins, of their research laboratory, my thanks are due for their coöperation and nterest in what was required.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Control of Diphtheria in Institutions.

A meeting of the Naval, Military, and Air Force Hygiene Group of this Society was held on May 3rd with Major-General H. P. W. Barrow, the President, in the chair. A discussion took place on the Problem of Diphtheria Control in Crowded Institutions.

Surg. Commander S. F. Dudley said that he had had a good deal of experience of diphtheria from the clinical, administrative, and bacteriological points of view. Although virulent Klebs-Löffler bacilli might give rise to the atoxic variety, it might, for practical purposes, be said that the reverse change never occurred. People who were immune to diphtheria because they possessed natural antitoxin in their blood were distinguished from those who had little or none by the Schick reaction. Sore-throats due to the diphtheria bacillus might be divided into three groups. The first included typical diphtheritic throats with an exudate pathognomonic to the naked eye. The second was a large group with throats or a general condition suggestive of diphtheria. These were especially common in crowded institutions, and if at all ill should be treated immediately with antitoxin without waiting for the swab report. A negative report threw doubt on the diagnosis because the Klebs-Löffler bacillus was easily demonstrated in the majority of primary cultures. Virulent and avirulent strains were found in the same throat more often than had been realised; therefore a report of the presence of the atoxic variety did not invariably rule out diphtheria. In a mixed culture chance determined which variety was tested for toxigenicity. The third group comprised those whose throats contained the bacillus although the clinical condition did not suggest diphtheria. The question then arose: Was the case diphtheria or tonsillitis in a diphtheria carrier? It was commonly believed that avirulent bacilli could not cause sore-throat, but if the bacilli found were virulent the Schick reaction would solve the problem. A Schick negative excluded diphtheria, and Schick positive carriers of virulent Klebs-Löffler bacilli were so rare as to be negligible. In crowded establishments the combination of a sore-throat which was not diphtheria with a positive swab was not at all uncommon. 7 per cent. of some 4000 healthy boys had been proved to be carriers at the Royal Naval School, while 15 per cent. of the swabs from over 1000 non-membranous sore-throats grew the Klebs-Löffler organism. Where the virulence tests and Schick reactions of these boys were known they confirmed the deduction that about half were mild cases of diphtheria in partially immune Schick-positive reactors, the remainder being secondary infections in Schick-negative carriers. The third group rarely required antitoxin, and to swab their throats was only tempting providence. The use of the throat swab in diphtheria diagnosis was therefore limited. To withhold antitoxin until the report came was criminal, as irreparable harm might ensue in the 24 hours. Mistakes occasionally occurred, and Surg. Commander Dudley quoted two instructive cases where the report was negative on undoubted cases of diphtheria. A culture which was negative after 24 hours might show Klebs-Löffler bacilli a day later. This lag was not common in primary cultures, but was quite often seen in swabs from carriers. The bacilli must always be tested for virulence, or avirulent carriers would be unnecessarily detained. The ratio of virulent to avirulent bacilli varied enormously at different times, and after a variable period of contact with its host the virulent bacillus would change into or be replaced by the atoxic variety. The carriers of virulent bacilli with Schick positive reaction were so rare that they

might be neglected, so that virulence tests might be omitted if the reaction was positive.

Danger of the Throat Swab.

The attempt to eradicate by mass swabbing diphtheria which had once got a grip in a crowded institution was hopeless, owing to the intermittence of the carrier state and the fact that the vast majority of symptomless infections only lasted for a short time. Positive and negative findings might alternate for a few days, then a run of six negatives might be followed by a single positive or a run of positives. Surg. Commander Dudley's work thoroughly confirmed that of McCartney and Harvey.[1] A few boys were completely immune to carrier infection, but others became reinfected over and over again during their years at school. At least 75 per cent. of the boys who had passed through Greenwich School during the last seven years must have been infected with diphtheria at some time or other. A series of examinations had proved that boys might be negative one day and positive the next. These investigations had shown that it was not worth while to segregate carriers found experimentally. The carrier was not a pathological curiosity, and in dense populations the diphtheria patient was more a curiosity than the carrier. A simple deduction had shown that during the last three years at Greenwich School there must have been some 20 carriers of virulent bacilli to every clinical case of diphtheria, and about 3000 invisible and undiscovered infections with virulent bacilli. The diphtheria throat swab had been in many ways a curse; it might delay antitoxin treatment, and a positive report without a virulence or Schick test must have forced a wrong diagnosis on many non-specific throats, thus falsifying the notification returns. Two or three negative swabs constituted a very false standard of freedom. The results of every throat swab must be correlated with all other available clinical environmental data. The step of increasing air space in dormitories had been very successful in epidemic meningitis, but three feet between the beds seemed to be no barrier to the spread of diphtheria among British boys. A distance of 9 feet seemed to be necessary and would be quite impracticable under Service conditions. Nor would it be advisable in training establishments, because that was where the raw recruit was seasoned by contact with the organisms of his new environment. To protect the boy under training would only transfer the morbidity to sea-going ships where it would be far harder to treat and control.

Active Immunisation.

Active immunisation was a safe and efficient method of controlling diphtheria, and suffered from none of the disadvantages of other methods. Under natural conditions the whole population slowly acquired immunity; active immunisation merely hastened the natural processes, and had proved itself to be an almost certain method of eradicating symptomatic diphtheria. Active immunisation produced a solid and lasting immunity. Out of 1004 parents circularised from Greenwich School only 7 had refused to allow their boys to be immunised, which proved that there was no great public objection. Disasters which had occurred were almost certainly due to dissociation of toxin in improperly stored mixtures, or to overdosage. These errors and the danger of anaphylaxis could be eliminated by the use of a prophylactic containing neither toxin nor horse serum. A toxoid mixture was just as good if not better than the older toxin-antitoxin mixtures. The reactions after injection were negligible: a local redness and œdema the size of a half-crown. No boys complained of feeling ill, though 3 out of 400 had slight temperatures. With good organisation, a team of two medical officers and three assistants should be able to perform 200 intradermic or immunising injections in an hour. The cost of Schick toxin and prophylactic material for 1000 men with 40 per cent. positive reactors would be about £60, and that sum would be saved within the year if each case of diphtheria were estimated as costing £30. If the entrants at Greenwich School could have been immunised before 1920 about £10,000 would have been saved at a cost of £150. The new entrants were the most susceptible class and accounted for a large proportion of the symptomatic diphtherial infections; they were always segregated for their first three or four weeks. Last term they had had their first prophylactic dose some days before coming in contact with the old boys, among whom were many virulent carriers. The herd immunity to diphtheria started to rise as soon as the first batch of Schick positive reactors had been inoculated. Only two cases occurred during the term although the environment was exceptionally favourable for the dissemination of symptomless infection with both virulent and avirulent bacilli. Klebs-Löffler bacilli were found in over 200 primary cultures from apparently healthy boys. Surg. Commander Dudley felt confident that within six months diphtheria would have practically vanished from the Royal Naval School. He thought that diphtheria incidence could be reduced to a negligible figure and ultimately abolished from an institution by immunising the new comers and segregating them for a few weeks. This would avoid a large initial outlay in time and money, and might indirectly protect the whole population.

Discussion.

Colonel P. R. HENDERSON asked whether an intercurrent tonsillitis might delay the process of active immunisation, so that symptomatic cases appeared. This seemed to have happened at Caterham. Analysis of the barrack square dust had shown that it was 94 per cent. sharp pieces of silica, which might account for the sore-throats.

Major W. R. O'FARRELL did not agree that naked-eye diagnosis was the only investigation necessary; Vincent's angina might simulate diphtheria very closely. The "mild" cases of diphtheria were a distinct entity and required antitoxin; they should not be separated from diphtheria in any classification. He was in favour of the throat swab and had been unfortunate with the Schick test. Many of his cases had been Schick negative, and elderly people were often susceptible by the Schick test although they did not get diphtheria. He would rather trust the throat swab than the Schick reaction, although the latter was useful in eliminating a few cases before the administration of toxin-antitoxin.

Dr. GRAHAM FORBES expressed gratification that increasing numbers of metropolitan boroughs were affording facilities for diphtheria immunisation, and mentioned some of the results. He agreed that a 24-hour culture was insufficient and that a virulence test was essential. Before its introduction many school-children had been kept away unnecessarily. In the epidemic years, 66–70 per cent. of carriers had had virulent bacilli in their throats, but now the percentage was reversed. He asked how long the immunity lasted after active immunisation.

Sir WILFRED BEVERIDGE said that toxin-antitoxin mixture could never safely be sent to hot climates as it had to be packed in ice, and the ice killed the antitoxin and left the toxin. This was the cause of the disasters in Australia and America. The lesson was that tropical workers must learn to make their own toxin-antitoxin. A throat swab was insufficient; the nose must always be swabbed as well.

Dr. J. D. ROLLESTON said that his 30 years' experience of diphtheria confirmed what Surg. Commander Dudley had said. He mentioned diphtheritic whitlow, which rapidly cleared up under a dose of antitoxin. The idea that antitoxin was valueless after the fifth day he stigmatised as a "damnable doctrine"; so long as there was any membrane antitoxin should be given. He was so convinced of the futility of routine swabbing before discharge that he had discontinued the practice. As an example of the caprice of spontaneous immunisation he mentioned the case of his predecessor who, at the age of 3,

[1] See THE LANCET, Feb. 4th, p. 245.

er 42 years as medical officer to a fever hospital, d developed diphtheria with severe paralysis.

The PRESIDENT asked if active immunisation uld be practical for recruits who were only under servation in their depôts for five or six months.

Reply.

Commander DUDLEY, in reply, said that the Schick ction only showed a limit of antitoxin in the blood; was possible for a person to be in a pre-immune dition with no antitoxin in the blood and a nick positive. Injection would then put him in a sition to resist diphtheria in a much shorter time an was realised. The injection he used was simple toid with no antitoxin, and this avoided all asters. He thought that a lot of the epidemiological culiarities of diphtheria were due to changes in the ganism itself. The theory of the immutability of virulent and avirulent strains could not be sup-rted in the light of recent unpublished work.

OPHTHALMOLOGICAL SOCIETY.

ANNUAL CONGRESS.

(*Concluded from p. 860.*)

Mr. E. WOLFF read a paper (by himself and Mr. F. VIES) on

Fragmentation of the Retinal Blood Stream.

e said this phenomenon was generally regarded a post-mortem one, and had been suggested as a eans of proving the difference between death and ch simulating conditions as cataleptic trance or parent death from drowning. But his colleague and , in some experimental work on the production of inal œdema, found a method of producing and olisbing fragmentation at will in the living animal. e condition was first described by Bouchut in 1869, d Mr. Usher had shown that just before death the od in the vessels took on a finely granular pearance, then became coarsely granular, and then mented, or beaded. Bulmer compared this picture h that of a chain of anthrax bacilli. Usher noted t at times spontaneous respiration might be con-ued after the onset of this granular appearance. hn, in 1916, said he regarded segmentation of the inal blood stream as an absolute sign of death. at this was not so was proved by the following periment. Working on cats, Mr. Wolff and Mr. vies tied the innominate and subclavian arteries, ich are the only branches of the aortic arch in s animal and also the superior vena cava. Frag-ntation became clearly evident; when the ligatures these vessels were released the phenomena dis-peared and could be reproduced at will. According Mr. Wolff and his collaborator the segmentation the blood stream was influenced by the following tors: the slowing of the blood stream; the size of the sel; the type of the corpuscle; the type of serum; type of lining endothelium; and possibly the ssure on the vessel—i.e., the intra-ocular tension. e sequence of events was as follows: the arteries ame fine threads almost at once; the granular pearance of the blood and visible streaming in veins were noted in 10 seconds; fragmentation s noted in 35 seconds. The authors of the per agreed with Gayet that the segmentation n and all other ophthalmoscopic signs of death had their importance in proportion to the amount of eful study which had been given to them.

The paper was discussed by Mr. A. W. ORMOND, . GRAY CLEGG, and the PRESIDENT.

The afternoon of April 19th was given up to the mination and discussion of a large number of nical cases at Moorfields. In the evening a discus-n took place on the

Causes and Treatment of Iridocyclitis with Raised Tension.

Mr. R. AFFLECK GREEVES, in opening, said he umed that the discussion was mainly concerned h raised intra-ocular tension in the active stages of iridocyclitis. The causes and treatment of this condition, as distinct from the secondary glaucoma which arose from the inflammatory process, had received but scant attention not only in text-books but in the literature. In many varieties of glaucoma there was a rise of tension due to a blocking of the excretory angle; but glaucoma could exist in association with a normal or increased depth of the anterior chamber, and in the absence of any apposition or adhesion of the iris root to the corneal periphery. In 1913 he suggested that the cause of the deepening of the anterior chamber in iridocyclitis, which might occur independently of a rise of tension, depended upon osmosis; the colloids in the anterior chamber would take up water, the vitreous body would lose it, and so the lens and iris would move back. There was now considerable evidence that the intra-ocular fluid was a transudate from the capillaries of the ciliary body, and Mr. Duke-Elder's work supported this idea. Intra-ocular pressure could be varied by changing the relative compositions of the blood and aqueous, a condition which must occur in inflammations of the ciliary body because of the increased permeability of the capillary walls. Such conditions might be factors in the causation of glaucoma in cases of serous iridocyclitis. The latter two conditions occurred most frequently in middle aged and elderly people whose anterior chamber was usually shallow. This was apparently a different type of case from that of iridocyclitis with raised tension in which the anterior chamber was either normal or increased in depth, as in them the onset of the inflammatory process was sufficient to induce the condition. This kind of case was made worse by the use of mydriatics, while miotics often caused a fall of tension. Yet it was not the case that mydriatics were always successful in people who had a deep or a normal anterior chamber. In more than one case he had noted that atropine at first raised the tension, while eserine reduced it, but after treating with a miotic for some days, so lowering the tension, atropine could be used with impunity.

In these cases there was much difference of opinion on the question of mydriatics versus miotics. The general line of treatment which Mr. Greeves usually adopted was to use a miotic when the particular anterior chamber was shallow and the appearance of the eye suggested a predisposition to glaucoma. For a deep or normal anterior chamber he instilled homatropine, and, if this proved beneficial, he continued with atropine. If, however, the tension remained raised or was increased he resorted to miotics. If definite improvement followed this and tension was normal for some days he again used a mydriatic.

Mr. W. H. MCMULLEN commented on the great variety in the histories and clinical pictures presented by cases in which iridocyclitis had been accompanied by increased tension. Many tended to conform to one of three types: (1) Those in which increased tension occurred soon after inflammation set in; (2) those cases of glaucoma in which uveal inflammation could be found; (3) cases of chronic iridocyclitis in which increase of tension occurred months, perhaps years, after the onset of obvious inflammation. With regard to the treatment of class (1) there were two distinct schools. One stressed the danger of provoking high tension by using mydriatics, advised great caution in their use, and urged the use of a miotic instead on the slightest increase of tension. The other school insisted on the great value of mydriatics, and thought they should be used boldly and freely. They said the surgeon should be prepared to operate should a considerable rise of tension occur. Mr. McMullen accepted the teaching of this second school. In this type the great cause of the high tension was the iridocyclitis, and the most effective means of relieving the inflammation should therefore be adopted, especially as rest was so important. Dilatation of the pupil was also desirable, so as to prevent the formation of synechiæ. Sometimes rest in bed, purging, diaphoresis, leeching, the local application of heat, and the continued use of atropine caused a fairly acute rise of tension to subside within 24 hours, without operation.

He described the operative measures when these were needed. In type (2) the history might be exactly similar to that of primary glaucoma, and very careful examination with the slit-lamp might be necessary to detect the few spots of keratitis punctata or other evidence of inflammation of the uvea. The treatment of this class of case presented a difficult problem, as more was required to be known about the ætiology and pathology. His experience was that these cases did not do well on atropine, or on atropine and paracentesis. Sometimes miotics quickly relieved tension, but it quickly rose again. In most cases operation was required to bring about a permanent reduction of tension, either iridectomy alone or combined with fistulisation. In acute or subacute glaucoma with very slight signs of uveal inflammation medical treatment should not be continued long. The operation he preferred was Lagrange's. In type (3) there might be an insidious increase of tension, which could easily be overlooked until it had caused cupping of the disc and defective fields of vision. Medical treatment sometimes reduced the tension here, but recurrence was likely, and operation was needed permanently to relieve the tension. No method but operation was likely to be effective when the glaucoma was chronic, with cupping of the disc. The choice of the operation must be related to the condition of the eye, the aim being to produce a filtering scar.

Sir ARNOLD LAWSON said he did not remember having had a case in which he derived satisfaction from the use of a miotic. He felt that the use of atropine could not be wrong, and the reason it did not always act in the way it was hoped was that the inflammation had not been, at the time, successfully controlled. Often the causal factor was obvious, for the patient's Wassermann was strongly positive, or oral sepsis might be present, though it was a danger to seek to attribute to mild oral sepsis because such was found, any disease which might be present in the body. Vaccines in these cases he had found to be very disappointing. Paracentesis should not be persisted in if it had failed two or three times. He favoured anterior sclerectomy with a small iridectomy.

Mr. J. GRAY CLEGG said that in 27 years he had found that in his hospital 146 cases of iridocyclitis were severe enough to warrant in-patient treatment, and 55 of them presented definite raised tension which was not due to occlusion of the pupil. In the 55 cases the underlying causes were: syphilis in 6, tubercle in 2, a septic focus in 12. In 35 the cause was not found. It was his practice always to try medical methods first, and only when these failed to restore normal tension to the globe did he operate. He described his medical procedures. Non-operative measures were successful in 23 of the 55 cases, but the abnormal tension was liable to return. The operation he now carried out was paracentesis—which might have to be repeated several times—as iridectomy seemed to aggravate the inflammation. The ideal was to produce a permanent drainage from the anterior chamber.

Mr. T. HARRISON BUTLER thought that no case which had a florid iridocyclitis and approximated to sympathetic trouble should be operated upon if it could at all be avoided. Observing pigment on the posterior surface of the cornea was not necessarily an indication of an inflammatory process; it might show senile degeneration. In the florid acute cases the use of eserine was apt to be disastrous. Most of the cases occurred in women, and it was always wise to have their genital region investigated and put right by an expert.

Mr. A. L. WHITEHEAD said he had found, in a large number of these cases in women, some definite diseased condition—usually septic—in the vagina or uterus. But in others no cause could be found. Tuberculous iridocyclitis had been very rare in his experience. Sepsis and syphilis were much more frequent accompaniments. In the treatment of the eye itself he attached the greatest importance to the application of heat, both moist and dry, which could be carried out best by means of the electric pad. Hot irrigations of saline or boric acid for several minutes at a time and repeated was very valuable, as also was the applicati of leeches. Operation in these cases was frequent disastrous. Occasionally paracentesis had a ve good effect.

Colonel H. HERBERT spoke of the value of atropi in reducing tension in cases which were definitely d to iridocyclitis. Sclerectomy was too severe.

Other speakers followed, and the openers replied

On Friday morning the Congress discussed the

DIAGNOSIS AND TREATMENT OF INFLAMMATORY AFFECTIONS OF THE ORBIT.

Mr. NORMAN PATTERSON, in opening, said, as rhinologist, that inflammatory conditions affecti the orbit were in most instances secondary to infection of the nasal sinuses, and children were t chief subjects. Birch-Hirschfeld found that out 684 cases of orbital inflammation 409 were due to inflamed condition of the accessory sinus, and stat that the proportion would probably have been high if the nose and sinuses had been examined in eve case. The speaker's own conclusion was that disea of the antrum and sphenoidal sinuses was rare responsible for orbital conditions. In nasal obstructi the nasal drainage might be so checked that infecti passed into the orbit. Mr. Patterson detailed t nasal conditions usually found and the methods diagnosis. Orbital inflammation, he said, might occ very suddenly soon after the onset of a nasal catarr and at a later stage pain was increased by ocular mov ments. In all cases of orbital inflammation trar illumination should be carried out, and a thorou X ray study of the sinuses made. Thrombosis of t cavernous sinus might be secondary to orbit cellulitis, or it might arise by direct spread of infecti from one of the nasal sinuses, generally the sphenoi He considered treatment at some length, dividing into three heads: general, the treatment of the nas condition, and dealing with the orbital complicatio

Mr. A. F. MACCALLAN followed with an equal elaborate contribution from the ophthalmic side. I suggested the following classification: (1) injurie (2) primary osteomyelitis; (3) acute dacryo-adeniti (4) spread of inflammation from neighbouring par as in panophthalmitis, cavernous sinus thrombos infected wounds or abscesses of face, acute pharyngit periodontitis, infections of accessory sinuses, tub culous meningitis; (5) septicæmic condition (6) syphilis and tubercle; (7) orbital myiasis, asp gillosis, and actinomycosis. These he dealt with succession, and reported a number of illustrati cases.

Dr. P. WATSON-WILLIAMS, Mr. SOMERVIL HASTINGS, Mr. E. D. DAVIS, Mr. HARRISON BUTLE Sir WILLIAM LISTER, Dr. G. MACKAY, Mr. A. WHITEHEAD, and Mr. JAMESON EVANS took part in t discussion.

Among other papers read was one by Mr. CHARL GOULDEN on the

Illumination of the Field of Operation in Ophthalmic Surgery.

He said that for the attainment of the best resul two important conditions must be satisfied: (1) a sh focusing of the image of a homogeneous source light upon the part of the eye to be examine (2) the light must be so directed that all reflex fr any reflecting surface of the eye was avoided. T first condition was secured by the Lister operati lamp and the Hess Hamner lamp, but the avoidi of a reflex from the reflecting surface of the e during operations had not received sufficient consider tion; yet the illumination of the eye was too importa to be left to a nurse or other inexperienced pers The paper was devoted to the question of avoiding confusing corneal reflex and the brilliant glint of t knife or needle being used. For daylight operatir even in ophthalmic operating theatres, the bed w often put into a position which was not the be The operating table should be parallel with t window, with the eye in question towards the windo But even then lamps were essential for good illumin tion. The beam from the lamp should be direct

ver the forearm of the hand which was fixing the
ye, and should make with the patient's visual axis
s great an angle as possible without obstruction by
ıe brow and nose. Mr. Goulden gave the posi-
ons best adapted to various operations.

The Bowman lecture was delivered by Prof.
. ELLIOT SMITH, who dealt with

The New Vision.

Ie spoke of the importance to man of the transference
f function that had taken place in the brain during
volutionary processes. A new cortical area, known
s the neopallium, had been developed when the
ıammal had evolved from the primitive reptile,
ıd had gradually assumed functions formerly carried
ı by the mid-brain and other lower centres. Later,
ıe development of the macula lutea in monkeys
ıd man had provided a new type of vision, which
ıabled man to see the world and appreciate its mean-
ıg as no other living creature was able to do. This
ıller vision was dependent on structural changes. Prof.
lliot Smith traced the steps whereby in mammals the
ınctions of motor control, formerly exercised by the
uadrigeminal bodies, became vested in the cerebral
ɔrtex. This process was said to be incomplete in
ıe rabbit, the control of the hind-limbs being still
ɛtained by the mid-brain, whereas the cortex con-
ɔlled the movements of head, fore-limbs, and body.
earrangement of the fibres of the optic tract in the
igher mammals, associated with binocular vision,
rought about a further diminution in the power of
ɔntrol of the quadrigeminal bodies, and when the
ıacula lutea developed, the fibres from the percipient
ells in this area, which accounted for more than a
ıird of the optic nerve, increased greatly the pro-
ɔrtion of fibres going to the lateral geniculate body.
his body, losing much of its autonomy, became
ıore and more an intermediary between the retina
nd the neopallium. Thus, in man, almost the whole
ınction of visual perception became concentrated
ı the cerebral cortex, and he is thus enabled clearly
ɔ see, to understand, and to interpret what is
appening around him.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

A MEETING of this Section was held on April 20th,
ɔr. GIBBON FITZGIBBON, the President, in the chair.

Obstetric Practice at the Rotunda Hospital.

Dr. BETHEL SOLOMONS, Master of the Rotunda
Iospital, read the clinical report of the hospital for
he year 1926–27. He said that during the year
adiographic plant had been installed and had proved
seful both for obstetrical diagnosis and for gynæ-
ological diagnosis and treatment; he explained how
elvimetry was done with X rays. The pathological
ıboratory had been reopened; the scope of the
ntenatal department had been greatly increased, and
small ward had been opened for the treatment of
ıfants. The number of Cæsarean sections was still
ırge in spite of every effort to avoid them, the
ɔwer segment being the chosen route. The treatment
f eclampsia had scarcely altered; morphine was used,
nd glucose was given by the mouth or rectum or
ıtravenously. Pituitrin, 0·5 c.cm., was injected
ıuring colon lavage, when the result was most satis-
actory. Fifty-three cases of antepartum hæmorrhage
ıad been treated without a death. Among the 3717
ɔatients admitted to hospital during the year there
ıad been 12 deaths (0·32 per cent.).

The PRESIDENT said that the treatment of septic
ases at the hospital was apparently much what it
ıad been at the end of his term as master. In the
ıst few years treatment by vaccines and antitoxins
ıad been largely dropped, but blood transfusion was a
ɔaluable measure. Cæsarean section via the lower
egment was more difficult than the classical operation, but its results were better. He did not think, however, that it would have a much greater influence on the recovery of a case which had been actually infected. In these circumstances drainage should always be done at the time of operation. He was convinced that in no case of accidental hæmorrhage was plugging of the cervix indicated; he had seen disastrous results from this practice.

Sir WILLIAM SMYLY referred to improvement in the service of the hospital during the year of Dr.Solomons's mastership, and advocated use of the term "eclamp-sism" recommended by Dr. Bar for cases in which there were no convulsions, instead of "pre-eclamptic"; whilst "eclamptic" should be reserved for cases with convulsions. It was remarkable that there had been three cases of unruptured tubal pregnancy within the 12 months.

Dr. LOUIS CASSIDY thought that vaginal plugging should only be done if the cervix was completely closed and should not be used except in an emergency. At the Coombe Hospital it had been found that at least half of the women who developed sepsis had not been interfered with. He believed that there were three causes for sepsis—namely, external contamination, a septic focus in the body (e.g., in the teeth), and residual urine in the bladder. He felt that Cæsarean section was too largely employed at present. So long as there was no toxæmia or albuminuria the chances of delivery by the normal channels were generally good.

Dr. G. J. W. TIERNEY thought that the statement by Dr. Solomons in the report, that he would never perforate a living child, would add considerably to the prestige of the hospital. He noticed that in cases of induction of labour, oil, quinine, and pituitrin were given, but the last-named was never used if there was any disproportion. It seemed to him that if pituitrin was omitted because it brought about uterine contractions, then quinine and possibly also oil should be omitted; but he felt that where the disproportion was only slight all three might safely be used.

Dr. D. J. CANNON referred to the necessity of treating shock before hastening labour by rupture of the membranes.

Dr. A. H. DAVIDSON, speaking of the use of pituitrin in eclampsia in order to get the bowels to move, said that he thought this might be rather dangerous, as pituitrin raised the blood pressure, and might cause hæmorrhage into the brain or some other vital part. As a means of producing spinal anæsthesia he had found that 1·0 c.cm. of stovaine produced absolutely perfect anæsthesia for 1 hour and 40 minutes; and that there was no necessity to give 2·0 c.cm.

Dr. J. S. QUIN believed that the only treatment really of value in septic cases was blood transfusion.

Prof. R. J. ROWLETTE was glad to notice that in septic cases Dr. Solomons had returned to some extent to the use of vaccines, and hoped that this would reduce the mortality.

Dr. N. MCI. FALKINER suggested that a detailed report of the cases that attended the antenatal department and were delivered in the Rotunda Hospital should be kept, and compared with those cases which did not attend the department.

SECTION OF ANATOMY AND PHYSIOLOGY.

A MEETING of this Section was held on March 23rd, Prof. J. O'C. O'CONNOR, the President, in the chair.

Dr. W. R. AYKROYD read a paper on

Vitamin-A Deficiency in Newfoundland.

He said that Newfoundlanders as a people lived on a diet deficient in fat-soluble and other vitamins. Functional hemeralopia, not directly associated with beri-beri or scurvy, occurred amongst them and was rapidly cured by foods rich in vitamin A. A similar condition due to failure in synthesis of rhodopsin occurred in rats starved of vitamin A. Deficiency of vitamin A had not been definitely associated with any other condition in Newfoundland.

The PRESIDENT, commenting on the fact that a people who supply the greater part of the world with

vitamin A should suffer from lack of it themselves, said that in Denmark during the war there was for the first time a complete disappearance of deficiency diseases owing to the fact that the Danes were then unable to export all their butter. He asked whether in Newfoundland the workers who prepared the oil were subject to night-blindness.

Dr. R. E. STEEN inquired whether shortage of vitamin A had any share in the causation of rickets, and after other contributions to the discussion Dr. AYKROYD, in reply, said that the fishermen who actually handled the oil did so in a weak light, and therefore do not suffer from functional hermeralopia. In his opinion vitamin A had no share in the causation of rickets and in his series of cases the ocular symptoms appeared by themselves, and were unaccompanied by rickets.

Prof. A. F. DIXON showed three specimens of double monsters, with varying degrees of duplicity.

THE ROYAL SOCIETY.

PHYSIOLOGY OF THE CEREBRAL HEMISPHERES.

ON May 10th Prof. IVAN PAVLOV, a Foreign Member of the Society, delivered the Croonian Lecture on Certain Problems in the Physiology of the Cerebral Hemispheres. The following is an abstract of his address :—

The function of the nervous system is to maintain dynamic equilibrium within the organism and between the organism and its environment. In the latter case the equilibrium is, in the higher animals, extremely complex and is achieved mainly by means of the hemispheres. These continuously analyse and synthesise events occurring in the environment, and in correspondence with its changes establish temporary connexions between events, whether simple or complex, and various activities of the organism, in particular those of the skeleto-muscular system which is preponderantly concerned in reacting to environmental changes and is likewise itself highly differential and integrative in its response.

At present the physiology of the hemispheres exists only in outline—as a framework consisting of only a limited number of known factors, such as excitation and inhibition, their two-directional movement in the form of irradiation and concentration, and their mutual induction. The working out of the innumerable details of their intimate mechanism is a colossal problem of the future. Some observations comprising investigations carried out by Prof. Pavlov and his co-workers, subsequent to the publication of his book on "Conditioned Reflexes," are summarised.

Mechanism of Conditioned Reflexes.

The development of new temporary connexions between external agencies and definite reactions of the organism (development of conditioned reflexes) depends on the coincidence in time of the action of these agencies upon the receptor mechanisms of the organism with the various activities of the organism evoked either by external stimuli effective since birth, or by external stimuli which have become established as such after birth, or finally by changes in the internal condition of the organism (automatic stimuli). Under these conditions the formation of the connexion is a physiological law.

In order to become a firmly established, powerful, conditioned stimulus the external stimulus must begin to act slightly before the particular activity of the organism, and may even cease a few seconds before the beginning of the activity. If, on the other hand, the given activity constantly begins before the stimulus, either no connexion is established or if any is established it is weak, and survives only for a short time, and the specialised excitatory effect of the stimulus is invariably replaced by general inhibition. The biological significance of this fact is not yet clear. Where the stimulus begins to act before the given activity of the organism and continues during that activity the reflex tends to increase in strength and stability. The mechanism underlying these phenomena cannot be expressed in terms of the general properties of the cortical tissue without further investigation.

Analysis of Stimuli.

The analysing activity of the nervous system is founded in the first instance on the peripheral receptor organs, which constitute not only a receptive mechanism but also an analysing apparatus of the organism. To the peripheral points of the analyser separate points correspond in the cortex (the primary and simplest cortical mosaic). A good proof of this is that by applying definite external stimuli belonging to the same analyser—e.g., different auditory stimuli—it is possible to produce various disturbances or fatigue at different strictly localised cortical points. In this manner a very delicate method is opened up for investigating the construction of the cortical parts of the analysers, and it is possible to distinguish special areas in the cortex corresponding to the different analysers (visual, auditory, &c.) from certain other cortical elements of those analysers, which are dispersed probably over the whole mass of the cortex of the hemispheres. Not only are these dispersed elements incapable of performing any higher synthesis and analysis, but they have a very low degree of vitality, as evidenced by the rapidity of their transition into an inhibitory state under the influence of external stimuli.

Excitation and Inhibition.

The conditions determining the characteristics and the magnitude of the excitatory and the inhibitory effects of conditioned stimuli are bewilderingly complex and are only gradually being registered and classified. It is obvious that the magnitude of the positive effect is directly related to the amount of energy applied to the receptor organ. The phenomenon of summation of weak stimuli comes out clearly. The limit of normal excitability and the optimal strength of stimulation are also definite. In the case of very strong stimuli and of the summation of medium stimuli the excitatory process rapidly changes into an inhibitory one. Of course, the strength of stimulus is a relative quantity, varying greatly with individual differences of nervous system.

Since most probably the points between which the new connexions are established are in the cortex, it follows that the variations in the effect of conditioned stimuli will be dependent on the mutual relation between the different cortical points corresponding to the different conditioned stimuli, and also between the different points of those areas of the hemisphere which are affected by the unconditioned stimulus. For instance, the conditioned stimuli, based on food and acid respectively, both become connected with the chemical analyser of the hemispheres and therefore if in the experiments both sets of conditioned stimuli are used, their effect will be determined not only by the inter-relation of the points corresponding to the stimuli, but also by the relation existing between the alimentary and "acid" points of the chemical analyser.

Psychological Types.

The accumulation of observations upon the normal and pathological activities of the hemispheres gives grounds for distinguishing various types of nervous system. There is the excitable type, which always displays partial or complete failure when confronted by difficult relations between the excitatory and inhibitory processes, and which, if the experiments are continued, ends by developing an abnormal and extremely protracted weakening of the inhibitory activity, attended by an exaggerated general excitation. At the other extreme stands the inhibitable type which very easily becomes subjected to inhibition by stimuli either unusual or slightly stronger than usual, and which when confronted by comparatively difficult relations between the excitatory and inhibitory processes passes into a state of complete inhibition for prolonged periods of time. In between can be placed the well-balanced type which, successfully and without any signs of abnormality, establishes in a

ases a balance between the opposed nervous processes. This type comprises two varieties of animal, differing greatly from one another in external appearance—he stolid animal, always quiet, and the animal which s lively under ordinary conditions, but becomes drowsy with surprising rapidity under monotonous conditions. The latter variety has some difficulty in obtaining a balance between the two processes. This grouping of the types of nervous system corresponds closely to the ancient classification of temperaments; he excitable type—choleric temperament; the inhibitble type—melancholic; the quiet, balanced type—phlegmatic; the lively balanced type—sanguine.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of the Scottish branch of this Society vas held at Glasgow on May 2nd, when Dr. R. L. KAHN gave a lecture on the

Clinical Aspects of the Kahn Reaction.

He began by reviewing the history of the serum diagnosis of syphilis, touching upon the discovery of *Spirochæta pallida* by Schaudinn and Hofmann; the evelopment of our knowledge of complement-fixation y Bordet and Gengou, and the evolution of the Vassermann test by Wassermann, Neisser, and Bruck. After discussing the early attempts—beginning with Michaelis in 1907—to develop a precipitation test for yphilis, and describing the work of Sachs and Georgi, Meinicke, and Dreyer and Ward, he went on to give n account of his own earlier studies of precipitation. He had shown the requirements for optimal precipitaion results, when syphilitic serum was mixed with an ntigen-saline suspension, to be as follows: (1) optimal oncentration of antigenic lipoids in the antigen, xcessive or deficient concentration preventing preipitation. (2) Proper physical state of antigen uspension. (3) Correct quantitative relation between erum and antigen suspension; the number of antigen nits must not exceed the number of serum units. 4) Shaking, as a probable means of hastening collision etween the interacting particles. (5) Dilution of the ixture of serum and antigen suspension should be inimal. These observations formed the basis of he Kahn test. The outstanding features of the est were: (1) relative simplicity in performance; 2) rapidity in obtaining results, the test requiring o incubation and being completed after shaking the agents (serum and antigen suspension) for three inutes; (3) relative economy; (4) availability in l parts of the world; (5) application to research in xtending our knowledge of serum diagnosis of syphilis. s to the relation between the Kahn and Wassermann ests, Dr. Kahn claimed that the interaction between erum and antigen was the same in both tests. The sult of this interaction was directly visible in the ahn test by the formation of a precipitate, while in he Wassermann test, the result being invisible, a ecial indicator (the hæmolytic system) was employed o render the reaction visible.

The test was highly specific for syphilis and was naffected by pathological conditions other than yphilis. Dr. Kahn insisted, however, that it should e used only as an aid in the diagnosis and treatment of yphilis and should not supplant careful clinical study f each and every case. He concluded his lecture by iscussing the additional procedures of the Kahn action, including the quantitative serum procedure, he qualitative and quantitative spinal fluid procedures, nd the more sensitive "presumptive" procedure.

WEST SURREY HOSPITAL LEAGUE.—This organisaon, which has just come into existence, seeks to establish mass contributory scheme which in return for a contribution 3*d.* or 4*d.* per week will entitle the contributor and his mily to treatment at the Royal Surrey County Hospital the local cottage hospitals. The Cranleigh Village Hospital nd the Farnham Cottage Hospital have already joined the heme.

Reviews and Notices of Books.

BEDSIDE DIAGNOSIS.

By American Authors. Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University School of Medicine, Attending Physician to the New Haven Hospital. London and Philadelphia: W. B. Saunders Company. 1928. In three volumes totalling 2820 pages, with 890 illustrations and separate index volume to the entire work. Per set, £6 15*s.*

THE title of this work is designed to call attention to the fact that it is an attempt to emphasise the importance of diagnosis without extensive laboratory equipment. Many patients still have to be treated in their own homes, where facilities for diagnosis are limited to clinical examination with only such aids to the senses as the stethoscope and the thermometer. The authors hold that more accurate aids will never replace the older and simpler methods, while not minimising the importance of any kind of diagnostic test when it is available. Deliberately, then, they have omitted details of laboratory procedures while indicating their value, especially when combined with clinical observation.

The first volume of the book contains sections on infectious diseases, the intoxications (which are subdivided into those due to chemical poisons, those due to food poisons, and those due to acidosis and alkalosis), deficiency diseases, allergic diseases, diseases due to physical agencies such as compressed air illness and electric shock, metabolic diseases, developmental diseases, diseases of the locomotor system, and diseases of the digestive system. Diabetes mellitus is included in the section on metabolism because, although technically it should be placed with the endocrine disorders, actually its management is usually in the hands of those specially interested in the former group. The second volume contains sections on diseases of the liver, gall-bladder and bile-ducts, the pancreas, the peritoneum, the bronchi and lungs, the mediastinum, the circulatory organs, the blood-vessels, the blood-forming organs, lymph glands and spleen, and the urinary system. The third volume deals with diseases of the endocrine system and of the nervous system; here are included chapters on the muscular dystrophies and myasthenia gravis, on mental disorders and feeblemindedness. In relation to each disease the history is first described; physical signs are then set out in detail and their importance weighed; a summary is then given of the more complicated methods of diagnosis, with an assessment of their relative values, and finally the differential diagnosis is discussed. The subject is then completed by a short bibliography. Occasionally clear descriptions of actual cases are included. These are well chosen and not too numerous. An extremely high standard is maintained throughout, and the authors seem to have a happy knack of setting out just those points which are likely to be of use in difficult cases. The section on diseases of the circulatory system contains a preliminary chapter by Dr. W. J. Kerr on instrumental aids in diagnosis. In this he discusses the value of X rays, the sphygmograph, the polygraph, and the electrocardiograph, pointing out that if a constant endeavour is made to discover the clinical manifestations associated with changes recorded by instrumental means, it is usually possible to dispense eventually with such aids for routine work. The diagnosis of congenital cardiac disease is dealt with very fully in a section of 150 pages containing many clear diagrams. Of the other chapters in this section those on angina pectoris and disorders of the heart-beat should prove especially helpful.

In the section on diseases of the kidney clinical methods are again emphasised. The laboratory tests which are regarded as of most value in estimating renal function are the phenolphthalein test, the two-hour renal test, and the blood-urea nitrogen. Diseases of

the endocrine system are described by Dr. Hans Lisser, who holds that the great majority of these are due primarily to disease of one gland, although other glands are subsequently disturbed. He considers that the doctrine of pluriglandular disease has led to much confusion in diagnosis besides leading to the practice of unscientific pluriglandular therapy. Subsequent chapters stress the uniglandular prominence of endocrinopathies, and give as clear and simple a picture as possible of the disorders associated with each. Their value to the diagnostician is greatly increased by excellent photographs and descriptions of actual cases. The section on disease of the central nervous system is preceded by a description of its anatomy and physiology. A special feature here is the diagrammatic representation of sections from different parts of the cortex of the brain showing the type and arrangement of cells in each; diagrams showing the distribution of cutaneous nerves are also included. The book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed, but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided.

The physician will find it hard to get a finer book.

PATHOLOGY OF THE NERVOUS SYSTEM.

Nouveau Traité de Médecine. Publié dous la direction de MM. G. H. ROGER, F. WIDAL, et P. S. TEISSIER. Fasc. XXI. Pathologie du Système Nerveux: nerfs, sympathique, névroses. By Various Writers. Paris: Masson et Cie. With 415 illustrations. 1928. Pp. 900. Fr.85.

THIS fine addition to the volumes of the encyclopædic "Nouveau Traité de Médecine" contains long articles on neuralgia and on the lesions of peripheral and radicular nerves from the authoritative pen of Dr. J. Tinel. His study of traumatic nerve lesions, as was to be expected, is particularly well documented and illustrated, and includes a critical survey of the problems of causalgia. His conclusion is that this peculiar variety of neuralgia is always of reflex sympathetic origin, and that it can be treated successfully in more than one way. Periarterial sympathectomy is possibly less constantly helpful than alcoholisation of the injured nerve proximal to the lesion, the disadvantage of which, however, is the ensuing motor paralysis. A rather short, if concise, contribution is that by M. Chiray and M. Pavel on neuro-vegetative syndromes; interesting though it is, it serves at the same time to indicate how wide are the gaps in our knowledge of the sympathetic nervous system and how unsystematised still is our diagnostic insight into its affections. Comment of this kind is applicable also, possibly in minor degree, to problems of vasomotor and trophic disorder. The article by M. Parisot and M. Cornil makes very interesting reading, for acroparæsthesia, Raynaud's disease, intermittent claudication, acrocyanosis, are not exactly rare, and what is known of them is well summarised—yet there is a sad lack of precision about it all. Dejerine's intermittent claudication of the spinal cord is duly considered, but it is surely little else than a hypothetical explanation of symptoms capable of other pathogeneses. Acroparæsthesia can legitimately, we think, be made into a clinical entity, but its pathological basis stands in much need of substantiation. The sections on trophic disturbances (M. Heuyer, Prof. Marinesco) cover a rather surprising amount of clinical ground from melanodermia and sclerodermia to perforating ulcer and recurrent hydrarthrosis. Prof. Christiansen deals with the migraines; we wish he had said more of their pathogenesis—that is, of the method of production of migrainous syndromes; and more, too, of ophthalmoplegic migraine and its obscurities. Perhaps the longest and most controversial section in the volume is entitled "Neuroses-Dyskinesias," by M. Klippel and M. Weil. Embraced under this heading we find epilepsy, hysteria, neurasthenia, traumatic neurosis, the choreas, myoclonias, tics, tetany, and so forth. These articles reflect, as is perhaps natural, the viewpoints mainly of current French neurology, though we admit the catholicity of the bibliographical references; strong on the clinical and (where known) pathological side, they are undoubtedly weakest in discussion of the pathophysiology of the actual clinical symptom.

Nine hundred large pages, closely printed, devoted to but a restricted portion of the whole realm of neurology—here is a thesaurus for the neurologist to turn to for enrichment of his knowledge on both theoretical and practical sides.

HEALTH AND EXERCISE FOR GIRLS.

By ANNE M. ROBERTSON, B.A. (Hons. Lond.). with Illustrated Supplement of Practical Exercises designed by F. A. HORNIBROOK, and a Foreword by Sir BRUCE BRUCE-PORTER, K.B.E., C.M.G., M.D. London: William Heinemann, Ltd. 1928. Pp. 62. 5*s*.

IN his preface to this little book Sir Bruce Bruce-Porter writes that "those who are healthy will think in terms of health." We doubt it. Health is like social position; no one thinks of it unless there is something wrong with it. Mrs. Robertson deals with preventive medicine and physical culture from the point of view of a cultured lay woman. She puts forward the laws of health in a simple readable way; she shows that a human body needs as much care as a house to keep it in perfect order; cleanliness comes first, then diet. "Of all people that we know," she writes, "the citizens of Attica did the highest thinking on the lowest feeding. . . . The Greeks lived chiefly on porridge, wholemeal bread and water, taking only one or two meals daily." But this diet would hardly, we think, be popular among present-day school girls or their parents. In other directions the author gives much good advice, though it is easy to see that she is swayed by the idea that intestinal stasis is the root of all evil. Mrs. Hornbrook's supplement on practical exercises for growing girls suggests that games may be overdone and physically harmful, whereas systematic exercise can do much to promote beauty of form and perfect health. The book should be of help to parents and school-teachers.

BOLLES LEE'S MICROTOMIST'S VADE-MECUM.

A Handbook of the Methods of Microscopical Anatomy. Ninth edition. Edited by J. BRONTË GATENBY, M.A., Ph.D. Dub., B.Sc., D.Phil. Oxf., D.Sc. Lond., Professor of Zoology and Comparative Anatomy, Dublin University; and E. V. COWDRY, M.A., Ph.D., Rockefeller Institute for Medical Research, New York City. London: J. and A. Churchill. 1928. Pp. 710. 30*s*.

THE last edition of this invaluable work appeared in 1921, and histologists will welcome its successor. The book is essential to the microscopist, be he biologist, botanist, or pathologist. Little of the old matter has been dropped, and much new information has been added. The section on the histologic applications of measurements of acidity and alkalinity is as good as anything dealing with this highly complex business can be made; that on the culture of tissue in vitro is admirably clear in itself, and the references which it contains are sufficient to enable even the beginner in laboratory technique to embark upon this delicate branch of biological study. The section on micro-manipulative technique might with advantage have been made fuller or omitted. This is a subject almost impossible to set out in a handbook.

The value of this type of book depends largely on the skill with which its index has been compiled. Here the burden of effort seems to have been shifted entirely from the shoulders of the reader to those of the authors, and there need be no delay or disappointment in finding immediately information on any point within the wide scope of the book.

THE LANCET.

LONDON: SATURDAY, MAY 12, 1928.

RADIUM FOR CANCER.

ON the last day of 1927 we commented in these columns on the probable future of the treatment of cancer with radium and predicted relatively rapid developments. The first five months of 1928 have amply justified our confidence, and to this our recent issues have testified. In March Mr. HAYWARD PINCH, Director of the Radium Institute, in the course of a discussion at the Royal Society of Medicine, predicted that in the very near future radium would form as much a part of the up-to-date surgeon's armamentarium as the scalpel. In the same month a discussion was held by the Medical Society of London on "Advances in the Treatment of Cancer of the Cervix," and here it became clear that the chief advance lay in the successful application of radium. The same subject was discussed in April at a meeting of the London Association of Medical Women's Federation, and here it was pointed out that in the Mayo and other clinics radium was now used exclusively for cancer of the cervix, even in operable cases. In THE LANCET of April 28th we published an important address by Prof. G. E. GASK, which gave a cautious but broad review of the work now being done on the use of radium and its emanation. Prof. GASK ended his address by a deliberate endorsement of Mr. PINCH'S prediction mentioned above, and since the speaker has been personally directing some of the research prosecuted at one of the most active centres in this country his opinion must carry great weight. Last week Prof. S. RUSS, physicist to the Middlesex Hospital, made a valuable contribution concerning the physical basis of radium dosage, and to-day we are able to offer perhaps the most important contribution of all in the shape of the record of the work done at Manchester upon radium treatment of carcinoma of the tongue and mouth by Dr. G. E. BIRKETT.

This country has lagged behind America and the continent of Europe in knowledge and practice of radium therapy, a fact partly to be accounted for by the comparatively small amount of radium available in Great Britain, so that original investigation has been undertaken only by a small number of workers. The result has been that few extensive reports of actual clinical work have been published here, and few people have had the opportunity of gaining first-hand impressions of its value from actual examination of patients treated. It is, ultimately, the practitioner to whom the appeal must be made, and he, not unnaturally, will demand concrete and convincing evidence of the efficacy of radium before he will extend his demand for the treatment to be applied to the particular patients under his care. To the practitioner, therefore, we commend the evidence contained in Dr. BIRKETT'S exceedingly important article, and to Dr. BIRKETT himself we offer congratulations on his results. Last year a most encouraging report upon radium treatment of the tongue was published in the *British Journal of Surgery* by Mr. STANFORD CADE, whose work had been carried out at the Westminster Hospital. The number of patients treated at this centre was comparatively small, but served to demonstrate that radium was capable of producing in the tongue and floor of the mouth remarkable benefit as regards disappearance of the local signs of disease and restoration of function to the tongue. Dr. BIRKETT has carried the work a stage further, and has driven home the conviction that radium has produced results which could have been obtained in no other way, and that the advantages of radium must inevitably be extended to the so-called "operable" patient as well as to the "inoperable" class with which Dr. BIRKETT has mainly had to deal. This distinction of classes will disappear with the purely surgical standpoint which gave it birth. Further confirmation of this view is to be found in a comprehensive article on "Operative and Radiological Treatment of Malignant Tumours of the Mouth" by ELIS BERVEN in a Scandinavian journal,[1] and additional important evidence may be expected when the International Convention on Cancer meets in London in July.

Mastery of the technique of radiotherapy is advancing swiftly and with it comes the dawn of a new era in the treatment of cancer. Already it has been mastered in the *local* treatment of carcinoma of the tongue and floor of the mouth, of the cervix uteri, and perhaps of the breast. If radium can effectively be brought into contact with a cancer the growth can be made to disappear. The question of the treatment of glandular and other metastases is bound up with the surgical opening up of routes to the deeper parts of the body, the so-called "surgery of access." The term "surgery of access" shows that even in the new era the radiologist and surgeon must work together; most efficient of all will be the man who can combine surgical with radiological technique in his own repertory. A very brief survey of this field has recently been published by Mr. A. B. and Mr. S. M. SMITH,[2] who have necessarily derived most of their information from the publications of continental radiologists. They point out that the mere possession of radium is not in itself sufficient for the production of good results. One operator, who took over the control of the work previously done by another, obtained with the same radium and the same apparatus strikingly inferior results until he had acquired the necessary clinical judgment; and this is begotten only of experience and constant practice. This observation suggests an important corollary. It is obviously of prime necessity for the credit and advancement of radiological work in this country that an entire hospital, with adequate equipment of beds and radium, should be devoted to its study. The Radium Institute has already done much in this direction, but its resources have not been adequate for the study of the larger problems. Is it too much to hope that a radium hospital may soon spring into existence? We have reasons for believing that even this seeming miracle may before long be an actuality, and the possibility raises the further problem of the provision of radium salts. The world is known to possess a considerable supply which is not yet in therapeutic use, and a virtual monopoly of its sale is possessed by a continental company. More than this, the importation of radium into Great Britain is very seriously hampered by the imposition of a Government duty which adds a third to the initial cost. It is obvious that this should be brought to the notice of the Cabinet, since by far the most important use for radium is its application to the treatment of cancer.

Whatever its uses may be in naval guns or other engines of war it is the duty of a humane Government to give greater encouragement to the alleviation of suffering and to the saving of human life than to the means of its destruction.

THE ERROR OF BALLONIUS.

IT is now some two and a half centuries ago that GUILLAUME DE BAILLOU, a medical graduate of Paris, first coined the attractive word "rheumatism" to include a group of painful affections of the joints. Though his little book was not published until long after his death, and then only in Latin, in which it is described by the editor as a truly golden pamphlet, BALLONIUS'S conception has been generally adopted and the word which he used has remained as an inclusive term covering our substantial ignorance of what it connotes. So long ago as 1864 HIRSCH conjectured that rheumatic fever was a specific infective disease, and 30 years later SINGER claimed it as an attenuated pyæmia of streptococcal origin; but while the acute rheumatism of childhood thus came to hold a distinct position within the group of rheumatic diseases, its name remains a source of confusion in the public mind; whilst the remaining conditions which share the title of "rheumatism" form an inchoate mass.

In no other group of diseases, perhaps, has the nomenclature been so confused as in the group of chronic rheumatic diseases. Three recent reports[1] from the Ministry of Health have each in turn called attention to this confusion and have endeavoured to throw some ray of light into it. The first of them, issued in 1924, was based upon the results of an inquiry addressed to insurance practitioners in England and Wales, of whom some 90 responded. Their observations are of particular value in elucidating what the term "rheumatism" ordinarily connotes in the mind of the general practitioners who are brought most closely in contact with it. One of them sent in records of 223 cases occurring in a panel practice of 4000 persons. After mature consideration of all their reports the medical officers at the Ministry, forming a committee on rheumatism, decided to classify rheumatic diseases into the three main groups: (*a*) acute rheumatism (rheumatic fever, together with subacute rheumatism); (*b*) non-articular manifestations of so-called "rheumatism" (muscular rheumatism and fibrositis); and (*c*) diseases characterised by chronic joint change. It was after considering the conflicting pronouncements of recognised authorities that this modest clinical classification was adopted; for the terms "rheumatoid arthritis," "osteo-arthritis," and "arthritis deformans" were regarded as synonymous by some and as possessing distinctive shades of meaning by others. One agent of exactitude is lacking because these conditions are rarely fatal. Although they account for a drain on health insurance funds, amounting to at least one-fourteenth of the total sum paid in sickness and disablement benefit, their names do not often appear on death certificates. When, however, rheumatism or arthritis is included among causes of death, the Registrar-General is in the habit of asking for further information, although he accepts as adequate such terms as subacute rheumatism or rheumatic gout. In the latest report from the Ministry, Dr. ALISON GLOVER once more finds himself unable to define the significance of the older terms, and quotes conflicting definitions. For himself he is willing to recognise—setting aside gout—the two broad groups of rheumatoid arthritis and osteo-arthritis, while the climacteric arthritis of women at the menopause is considered by some sufficiently clear-cut to deserve a class to itself. About 10 to 15 per cent. of the total cases of chronic arthritis are so intractable to treatment as to have produced a wide-spread impression that we are here dealing with an incurable disease. He is, however, satisfied that one-third of all cases could be cured, at least another third relieved, and that in few chronic diseases is early and proper treatment so effectual. An appendix on the treatment of rheumatic diseases abroad, written by Dr. R. FORTESCUE FOX and Dr. MARGARETHE MAUTNER, will prove valuable at a time when a more progressive attitude towards rheumatism in this country is at last being reflected in action.

DR. GLOVER'S report appears most happily on the eve of the Bath Conference. This Conference, which is proceeding under the presidency of Sir GEORGE NEWMAN, whose opening remarks appear on another page, has as one of its main objects to obtain some orderly definition of the pathological conditions covered by the term "rheumatic diseases" in order to facilitate systematic inquiry into the predisposing factors of the different groups. The Conference, however, will have proved a failure unless it recognises the value of action as well as theory. The fundamental uncertainties of diagnosis, for instance, can best be cleared up by continual and intensive study at an early stage. The situation demands that we should be pragmatists, facing problems as well as relationships and the so-called rheumatic diseases present several which are for all practical purposes distinct. First there is the prevention, treatment, and care of heart disease in children; secondly, there is the need to prevent or diminish the damage done by focal sepsis in both adults and children; and, thirdly, there is the problem of ambulatory or palliative treatment in adults alone. The knowledge we already have is sufficient to do much good if it were properly applied. The conference at Bath may be taken as a symptomatic of the new movement against rheumatism which, although more systematically conducted on the continent, has had its origin in this country. If it serves to concentrate attention on the practical and immediate aspects of the question it cannot fail to bear good fruit.

PULMONARY ATHEROMA.

ACQUIRED disease of the pulmonary artery and its branches is a rare post-mortem finding, but still rarer is diagnosis of the condition during life. Nevertheless evidence is accumulating that this lesion may be associated with a fairly definite clinical syndrome. AERZA, ARRILLAGA, and other South American writers have recorded under the title of "cardiacos negros" a group of cases in which the principal clinical manifestations are intense cyanosis with dyspnœa, hæmoptysis, somnolence, and polycythemia. Autopsy revealed atheromatous changes and dilatation of the pulmonary artery with extreme hypertrophy and dilatation of the right heart. These patients gave a history of having suffered from some chronic pulmonary complaint for many years before developing cardiac symptoms, and it is suggested that the characteristic lesion may be attributed to the effects of chronic emphysema on a pulmonary artery which

has been weakened by some intoxication or chronic infection such as syphilis or malaria. A very similar clinical syndrome was described by ROGERS in natives of Bengal in whom a syphilitic form of pulmonary atheroma led to enormous hypertrophy and dilatation of the right heart with dyspnœa and cardiac dropsy. In this country COOMBS, CLARKE, HADFIELD, and TODD [1] have recently recorded five cases of extreme cyanosis which post-mortem showed advanced changes in the pulmonary artery and its branches. They point out that in some of these cases there is no evidence of syphilis or of any antecedent lung disease. They suggest that another possible ætiological factor may be an inborn defect in the wall of the pulmonary artery, and that the dilatation and hypertrophy of the right heart which, as they remark, is greater than in any other acquired disease of the heart or lungs, is attributable to the impairment of the elastic properties of the arterial wall. When the cyanosis dates from birth, it is unlikely that a more precise clinical diagnosis than that of "congenital heart disease" will be possible, for it is only in such congenital lesions as pulmonary stenosis and patent ductus arteriosus that the auscultatory phenomena are sufficiently distinctive to enable the physician to determine more precisely the anatomical condition. It might be expected that dilatation or sclerosis of the pulmonary artery would always give rise to a basal murmur, but the cases reported by COOMBS and his associates show that this is not so, the murmur in some of their cases was confined to the region of the apex-beat and suggested a left-sided valvular defect. When, however, the physical signs of pulmonary or cardiac disease are insufficient to account for the presence of an intense cyanosis which first makes its appearance in adult life, pulmonary sclerosis is a possibility which deserves consideration, and corroborative evidence from X ray examination should be sought, since both the widening and the abnormal density of the shadow of the pulmonary artery are striking features. The facial appearance of these patients suggests polycythemia vera, and it is not improbable that some of the patients in whom that diagnosis is made, in the absence of splenic enlargement, are really suffering from pulmonary sclerosis. COOMBS and his co-workers do not regard mechanical stress as the primary factor in any of their own cases, though admitting that it is probably responsible for the arterial lesion in the type described by ARRILLAGA which supervened on a chronic pulmonary lesion. Somewhat similar though less pronounced changes in the structure of the pulmonary artery are found in old-standing cases of mitral stenosis and are presumably to be explained by the mechanical strain which this particular valvular lesion throws on the artery.

EXAMINATIONS FOR MENTAL NURSES.—The General Nursing Council for Scotland have replied in an open letter to the resolution passed by the Royal Medico-Psychological Association on Nov. 17th, 1928. This resolution was designed to secure that nurses who had passed the Association's examination for proficiency in mental nursing should be entitled to be placed on the register of the G.N.C., the examination being subject to such supervision and standard as the G.N.C. might see fit to impose. The G.N.C. for Scotland agree that it is regrettable that there should be two authorities conducting examinations, and in view of the fact that the Association desire to continue to issue their certificate they suggest that the preliminary examination of the General Nursing Council should be accepted by the Association, and that a final examination might be arranged jointly by the two bodies. It is suggested that a conference should take place for discussion of this proposal.

Annotations.

"Ne quid nimis."

THE NEW PHARMACOLOGY.

FOR 65 years the British Pharmaceutical Conference has issued with regularity a Year Book of Pharmacy, containing a record of the annual increase in our knowledge of drugs and their actions. It has been for the most part no hardship for the medical profession or indeed for the public to wait a year before these things were made known; they did not seem to touch human health and happiness very closely. But with the recent astonishing development of pharmacological research it has now been felt undesirable for the data so obtained to be held up for an annual publication; hence the appearance of the first number, dated January to March, 1928, of a *Quarterly Journal of Pharmacy and Allied Sciences*, which incorporates the Year Book of Pharmacy, and is published [1] by direction of the Council of the Pharmaceutical Society of Great Britain. In an introductory note to this first number Sir John Rose Bradford makes it clear what the new outlook means. Fifty years ago pharmacology was cultivated only by a small minority of teachers and investigators—Sir John singles out for honourable mention Christison and Fraser in Edinburgh, Brunton, Cash, and especially Ringer in London—and much of the therapeutic pessimism not uncommon a generation or two ago was due, as he points out, in part to the uncertain results then obtained with many drugs that were in truth valuable, but which failed owing to variation in potency. Digitalis is cited as a good instance, and the first article in this new publication deals with the pharmacological assay of digitalis by different methods, in which evidence is given to show that the international powder is a practicable standard for digitalis leaf and tincture in Great Britain. Its adoption would entirely remove from the practitioner's mind the disturbing reflection that failure of the heart to react to his treatment may be due to the inefficiency of the drug supplied to him. Sir John describes the preparation of the active substances elaborated by the ductless glands as an achievement of outstanding importance, for here, he says, we are dealing with a pharmacy that is almost indistinguishable from the normal physiology of the organism. The successful synthesis of these substances opens up a further vista of possibilities. Pharmacy, so long regarded as ancillary to medicine, has almost reached the time when the servant may be said to be as great as her master. This result is very largely due to the Pharmaceutical Society, established in 1841 for the purpose of advancing chemistry and pharmacy, which has achieved so much in spite of being a voluntary association with only a moral obligation to join its ranks. The school of pharmacy, which is now a school of the University of London, is more than 85 years old, and the research laboratories in connexion with it, founded in 1888, were extended in 1926 by the institution of a pharmacological laboratory for research on the standardisation of drugs and preparations by biological methods, with the addition last year of a department for the testing of material for vitamin content. It is the rapid development of the laboratory in the latter respect which will make the quarterly issue a matter of eager expectation. In this issue, for example, appears amongst other relevant articles, a note on a method of assay of the antirachitic vitamin D, by which the potency of any substance can be expressed in terms of this standard. The standard adopted by the Pharmaceutical Society is such that a daily dose of not more than 0·0001 mg. will produce complete healing of rickets induced in rats under the conditions described. The *Quarterly Journal* remains in the able hands of Dr. C. H. Hampshire, editor of the Year Book, with the assist-

ance of an editorial committee of which Mr. J. T. Humphrey is chairman, and the medical members of which are Dr. J. H. Burn, Dr. H. H. Dale, and Dr. W. E. Dixon. The success of the new publication is assured.

THE DOG AND CAT IN DERMATOLOGY.

So far as we know, the only cutaneous diseases that can be contracted from the dog or cat are scabies and ringworm, but in these days of domestic pets the chances of such infection are by no means remote. Hudelo and Rabut [1] state that the scabies of dogs, which is caused by an acarus morphologically similar but smaller than that of human scabies, is less common than the feline variety, which is due to the *Notaedris cati*, an even smaller parasite. Both infections seem to require prolonged and intimate contact with the offending animal—e.g., in bed—and neither parasite burrows in the human skin, thus rendering diagnosis a matter of doubt and difficulty. The presence of isolated intensely pruriginous papules, capped sometimes by a minute blister, usually on the flexor aspects of one or both forearms, or on the abdomen, or one shoulder, should arouse the suspicions of the practitioner and, in spite of the absence of acarine runs in the finger webs, on the breasts, or the penis should suggest an atypical scabietic infection. The possibility of animal transmission may make it necessary to examine the animal suspected. In the dog, according to Hudelo and Rabut, scabies is manifested by fine desquamation on the anterior borders of the ears; in advanced cases there is patchy loss of hair and an eruption of papules and pustules over most of the body. In the cat it may set up a generalised inflammation with greyish crusts spreading from the scalp, which is denuded of its hair, as far as the neck, such a condition being often severe and sometimes even fatal. A characteristic sign is coexistent infection of the paws from violent scratching of the ears. The treatment of scabies contracted from a cat is simple and the infection subsides almost as soon as the animal is removed. The canine variety is not so easily eliminated, and the inunction of sulphur or some antiparasitic ointment is usually necessary. As regards ringworm, the identification of the various species will demand a careful cultural technique, which Sabouraud has elaborated in his famous work, "Les Teignes." There are three great classes, the trichophytons, the microsporons, and favus. They may attack the glabrous skin and the hair both of the scalp and beard, and recently the important observation has been made that follicular eruptions on the back and chest of children are sometimes attributable to trichophytides, which have reached this secondary site by way of the blood stream.

THE STORAGE OF SPERMATOZOA.

WE have still much to learn about the physiology of the male reproductive system. Dr. Robert M. Oslund [2] tells us that in the course of a series of experiments involving ligation and resection of the vas deferens in animals he became interested in the question of the storage of spermatozoa. He found that in the seminiferous tubules there occurs an accumulation of colloid material derived from the breaking down of spermatocytes and spermatids. This colloidal fluid moves slowly along the tubules, its movement being determined by the vis a tergo rather than by active contraction on the part of the seminiferous walls. When the fluid enters the epididymal canal it comes under the action of the ciliated lining, but in the author's opinion the influence of this is insignificant in comparison with the force exerted by the accumulation of spermatic material behind it. The motility possessed by the spermatozoa probably does not exercise much influence on the progress of the fluid or of the spermatozoa through the tubules. Benoit has reported that the epididymis secretes a substance which nourishes and activates the sperm and states that spermatozoa are more active in the tail of the epididymis than they are in the head. Oslund was not able to confirm these observations and believes that the main motive power of the spermatozoa is derived from the pressure of secretion from behind. As far as he could see there is in man very little storage of spermatozoa anywhere in the genital tract. Certainly the vesiculæ seminales cannot be regarded as reservoirs and spermatozoa found within them in cadavers must be regarded as invaders rather than as normal inhabitants. As the result of the constant passage of sperm from the testis towards the urethra spermatozoa are found frequently in the urethra and in the urine. During coitus there occurs a speeding up of the movement of the sperm along the vas deferens. This is due to contraction of the muscles of the epididymis and vas deferens including the ampulla which decreases the volume of the tubules and forces spermatic fluid towards the urethra. These contractions are observed after stimulation of the hypogastric nerves; they also occur spontaneously and more especially during coitus when they supply the chief mechanism for the transportation of spermatic fluid.

THE BLOOD IN TUBERCULOSIS.

AFTER a cytological study of the blood in patients suffering from pulmonary tuberculosis, R. S. Cunningham and Edna H. Tomkins [1] claim that in this disease the white cells undergo very definite changes in number and character, and in particular that the monocytes are always multiplied. The "supra-vital" technique introduced by Sabin was employed in their investigation, as it facilitates differentiation between the monocytic and lymphocytic types. So convinced are these observers of the importance of this change that they would hesitate to accept a diagnosis of pulmonary tuberculosis if the patient's blood failed to show an elevation of the monocyte count. The lymphocytes show a reciprocal relationship to the monocytes. Thus the latter increase during infection while the former decrease, the monocyte serving as an index of dissemination and the lymphocyte of resistance. A progressive decrease of the lymphocyte count suggests a grave prognosis. It is possible that some specific toxin of tuberculosis acts as a stimulant to the monocytes and a depressant to the lymphocytes, so that the ratio between the two types of cell may thus be used as an index of the relation of the processes of infection to those of resistance. Enumeration of the white cells of the blood may thus, they consider, be useful in both diagnosis and prognosis.

THE BEGINNINGS OF LOCAL ANÆSTHESIA.

THE inestimable benefit that cocaine has proved to be as a local anæsthetic in eye surgery and the perhaps equal services that its synthetic derivatives now afford for infiltration anæsthesia render the history of the first employment of the drug of considerable interest. It is to Dr. Carl Koller, formerly of Vienna, now of New York, that ophthalmic surgeons owe the discovery of its practical application. In a personal communication he informs us that long before 1884 he had been conducting experiments with such substances as chloral, bromides, and morphia in the hope of obtaining an efficient local anæsthetic for the eye, but without success. The alkaloid cocaine had been isolated from coca leaves brought from Peru so long ago as 1860, and its numbing effects on the nerves of the tongue had been recorded, but lost sight of in view of the overshadowing effects of the drug on the central nervous system.

"When in the course of preparing for these physiological experiments," writes Dr. Koller, "I realised that I had in my possession the local anæsthetic which I had been previously striving for, I went at once to Stricker's laboratory, made a solution of cocaine, and instilled a drop in the

[1] American Review of Tuberculosis, March, 1928.

eye of a frog, and afterwards of a guinea-pig. I found the cornea and conjunctiva anæsthetic—that is, insensitive to mechanical, chemical, thermic, and faradic stimulation. Afterwards I repeated these experiments on myself, some colleagues, and many patients. I made the first preliminary communication relative to this subject on Sept. 15th, 1884, at the Heildelberg meeting of the German Ophthalmological Society. Dr. Brettauer, of Trieste, read a short paper which I had given him together with the solution to take to the meeting, and showed the experiments. On Oct. 17th of the same year I read before the Gesellschaft der Aerzte of Vienna a more elaborate paper which was published in the *Wiener Medizinische Wochenschrift* for Oct. 25th, 1884, and translated in THE LANCET (London) of Dec. 6th, 1884, and the *New York Medical Record*."

The news of the new drug which did away with the necessity of a general anæsthetic in nearly all eye operations spread with remarkable celerity. Already before the end of the year 1884 three papers on it were read before the Ophthalmological Society of the United Kingdom by the late Arthur H. Benson, the late E. Nettleship, and the late Walter Jessop.[1] Nettleship had already operated with cocaine for 18 senile cataracts, besides numerous other operations, his first operation having been on Oct. 10th, less than a month after Dr. Koller's paper had been read at Heidelberg. Its use soon became and has remained universal among ophthalmic surgeons. At Dr. Koller's suggestion the drug was shortly afterwards utilised by his laryngological colleagues. The employment of infiltration anæsthesia was a subsequent development. It is fitting that these facts should not be forgotten during the lifetime of the discoverer.

CHEMICAL CHANGES IN CULTURE MEDIA.

IT has been a reproach for many years to the bacteriologist that he has been too much occupied with certain aspects of his studies, particularly with pathogenicity and special differentiating tests, to pay proper attention to the nature of the chemical changes taking place in the media which he employs. These media are of a very complicated character, the difficulties of their investigation are correspondingly great, and progress cannot be other than slow. Reliable methods of estimation are, of course, a necessary precursor for any clear advance, and a recently issued report [2] embodies studies of this order and adds to the number of trustworthy methods now available. By the use of Foreman's alcohol titration method and its modifications it is possible to obtain what the authors call reliable balance-sheets, in which the total values for constituents estimated in groups are equal to the sum of the values for the subgroups. The methods used are described in the text. The "total alcohol value" of "alcohol extracts" made from such fluids as meat extract media, can be successfully differentiated into subvalues for the different classes of, and radicles embraced by, new rapid methods, and the results can be checked by balance-sheet methods. The medium used was a plain ox heart extract with tap water and without salt or peptone additions. The *Staphylococcus aureus* was grown in such extracts of differing concentration and the chemical and bacteriological changes were studied under different conditions. These changes are complex and only a few points can be noted. The curve of bacterial growth is characterised by two peaks, the first reaching its maximum on about the fourth day and the second on about the twenty-eighth day. Between them is a period in which the numbers are small, while after the second peak the numbers again decrease. These phases correspond to definite chemical changes. For example, during the first period of rapid growth there is the production of volatile bases alone, unaccompanied by any appreciable development of acids. Apparently amino-acids are not the source of the volatile bases. Before this first phase is completed the second phase, that of the production of volatile and non-volatile acid radicles, in approximately equal proportions, commences. In the third phase non-volatile acid radicles alone are produced. The second period of growth (about the twenty-eighth day) is chiefly characterised by the conversion of non-volatile acid radicles into equivalent amounts of volatile acids, and the content of volatile acids reaches its maximum by the time the second peak of growth has been reached. The inorganic phosphorus content also varies in relation to the organic phosphorus content. These and other chemical changes are best studied in relation to the charts shown.

A further report [3] by the same authors deals with the effects of certain salts upon changes in hydrogen-ion concentration, and with the rôle of creatinine in the control of reaction in cultures. The points discussed, which are of considerable technical interest, can only be appreciated by a study of the report itself.

COMPARATIVE IMMUNITY.

NEW journals devoted to one or another aspect of the medical sciences continue to emerge at frequent intervals. Among the latest is the *Archives roumaines de pathologie expérimentale et de microbiologie*, published in French, in Paris, and edited by Prof. J. Cantacuzène, of Bucharest, who occupies the greater part of the first number with an instalment of his researches on the mechanism of immunity in the marine gephyrean worm *Sipunculus*. It is a classical field, for it was when he was working with similar material, and when, as he tells us, his family had gone to a circus to see some extraordinary performing apes, that the revelation came to Metchnikoff, at Messina, in the early days of 1883, that phagocytosis was a means of protection against injury and disease. In the special case which he has investigated Prof. Cantacuzène shows that foreign bodies, such as bacteria or sheep's red corpuscles, injected into the cœlomic cavity are enveloped in leucocytes and gathered up into masses by the mucous secretion of the "urns," enormous ciliated cells whose function has long been something of a mystery. By these means the cœlom is soon cleared, and one is reminded of the way in which leucocytes and platelets clear the blood and the omentum clears the peritoneal cavity in mammals. Specimens of *Sipunculus* which have previously been vaccinated react in the same way, but quicker, the secretion of the "urns" is more acid and hence more adhesive and, in addition, agglutinins and cytolysins are produced, though, as is usual in invertebrates, the cellular side of the defence is much more active than the humoral. From which it may be surmised that the protective effect of vaccination is likely to be less specific than in the higher vertebrates. Such has indeed lately been shown by Chorine,[4] who found that various bacteria would immunise the caterpillars of the wax moth *Galleria* against the variety of *Bacillus subtilis* which is pathogenic for it.

TUMOURS OF THE LUNG.

MEDIASTINAL tumours have always had special interest, clinically and pathologically. Their increase in recent years and the recognition that the majority are not sarcomas of mediastinal glands but carcinomas arising from the larger bronchi makes any further information about them of value and we welcome a survey by Prof. T. Shennan of his experience in Aberdeen.[5] The 31 cases accumulated in some 12 years include a spindle-cell sarcoma of mediastinal glands, a lymphosarcoma of thymus, 4 tumours arising in the thymus with a structure resembling lymphadenoma, and 3 secondary thyroid carcinomas; the

[5] Jour. of Path. and Bact., 1928, xxxi., 365.

other 22 are carcinomas of lung. Nine of these are obviously epithelial in structure, while the other 13 belong to the well-known type with small oval cells which Prof. Shennan agrees with Mr. W. G. Barnard in interpreting as carcinomas. As usual, males predominated, only 4 of the cases being in women; in their occupations there is nothing suggestive, such as Dr. J. B. Duguid [6] found in Manchester. Anatomically however, it can hardly be without significance that some old-standing tuberculosis or fibrosis was present in at least 13 cases, and Prof. Shennan notes that many of the tumours arise from the main bronchi on which the chief incidence of influenzal catarrh falls; the suggestion has been made before that the recent increase in the prevalence of these tumours (which incidentally is not perceptible in the Aberdeen data) has something to do with the influenza epidemics of 1918 and 1919. Prof. Shennan increases the value of his paper by adding brief accounts of the clinical histories to his detailed anatomical and histological descriptions. The protean variety of the symptoms is particularly striking. One man dies suddenly with a profuse pulmonary hæmorrhage, another after many months of vague ill-health in which no localising symptoms were disentangled. The proneness of lung carcinomas to metastasis in the central nervous system is shown by the number of patients whose main or only symptom was due to this involvement; it might be headache or sciatica. It is also obvious that in a good many cases death is actually caused by secondary inflammations of the lung, due no doubt to the partial or complete blocking of the bronchi by the growth. In several instances profuse sweating, especially at night, was a prominent symptom.

ANÆSTHETICS IN GERMANY.

A PERUSAL of recent German medical periodicals brings to light the unusual amount of interest now being bestowed in that country on the subject of anæsthesia. Together with other continental countries Germany has suffered, and is still suffering, though to a diminishing extent, from the absence of medical men whose sole practice and chief interest is in anæsthetics. As a natural consequence the surgeon in those countries relies, much more than the English surgeon, on local analgesics whose application and effects he can himself study and control than on general anæsthetics, the safe administration of which requires the individual care of another skilled person. It was natural in these circumstances that "twilight sleep" should have its origin in Germany and find there its warmest support; for here appeared to be a method which provided many of the advantages of general anæsthesia without the same necessity for skilled attention to the patient during operation. In general surgery, however, "twilight sleep" has not provided a really satisfactory substitute for the administrations of skilled anæsthetists, and it has not, we believe, largely supplanted local analgesia in the majority of German clinics. An improved version of this method is said to give highly satisfactory results,[7] and the latest aspirant for answering those demands of the German surgeon which cannot be met by local methods is avertin. A large number, some thousands, of operations have now been conducted with the help of this rectal anæsthetic and the reports tend to be more uniformly appreciative than they were at first. A number of surgeons in whose clinics it has been widely employed have replied to a questionaire, and their answers show a large measure of agreement in commendation.[8] Some surgeons, however, regard the drug as too dangerous to be employed as a sole anæsthetic, although they approve of it warmly if used in small doses for the induction of unconsciousness and for the provision of a light narcosis which is rendered sufficient by very small amounts of inhalation anæsthetic. There seems to be universal agreement as to the pleasant nature of the induction of anæsthesia with this drug, and also as to the absence of deleterious after-effects. We are aware that avertin is now on trial at one or two London hospitals, and we look forward to an account of its estimation in this country.

TOBACCO ANGINA.

THE effect of tobacco-smoking on the body, and especially on the heart, is of particular and often of personal interest to medical men. Strangely enough, as Dr. Eli Moschcowitz [1] has lately pointed out, not many first-hand observations have been made on the effect of smoking on the heart, and most of the statements in current text-books bear the imprint of literary legacies. Whilst recognising that tobacco-smoking may bring about varying conditions such as tachycardia and auricular or ventricular extra-systoles, Dr. Moschcowitz has paid special attention to the pains simulating angina pectoris which occurred in four of his patients, probably as a result of excessive smoking. The features distinguishing tobacco angina from true angina pectoris are that it is more intense and of longer duration than true angina and is usually accompanied by little or no disturbance of the cardiac function; further that unlike true angina the pains are more likely to arise during complete rest, and may even awaken the patient from a sound sleep. An interesting feature to which Sir Humphry Rolleston has also drawn attention is that patients who have once had tobacco heart may show signs of sensitisation to tobacco smoke, and pain may be induced by smoking a cigarette, or even by being present in a smoke-laden atmosphere. The anginoid pains may arise in patients who have apparently healthy hearts, or in those who have previously shown signs of coronary or aortic disease. In both types the use of tobacco should be absolutely forbidden. It is not enough merely to reduce the amount of smoking. The pains do not cease immediately after the withdrawal of tobacco, but may persist for periods of time varying from a week to three months. The mechanism of tobacco angina is not known, but it is probably due to the constricting action of tobacco on the coronary blood-vessels. The pain bears a strong resemblance to true neuralgia in that it is not induced by exertion or emotion. All four patients described by Dr. Moschcowitz had smoked for many years; their ages varied from 35 to 62, and one was a woman who had smoked cigarettes to excess. Neither the variety of the tobacco used nor the form in which it is smoked seems to be a factor in the causation of the pain.

THE ROYAL ACADEMY.

THE 160th Exhibition of the Royal Academy of Arts was opened at Burlington House last Monday and has received the modified congratulation of the critics, who find the level of accomplishment high but the æsthetic interest moderate. Save that the practice of medicine and the art of drawing have many relations which always repay attention, the display in itself appealed to no special medical interests. First there is a dearth of medical portraits, which is to be regretted from the artistic point of view, since the head of the distinguished physician or surgeon very usually lends itself to especially fine treatment. For an intimacy of presentation is obtained here by the painter which is denied him when depicting public men whose features are familiar, while even in official medical portraits the dress has not the aggressive quality of full uniform, court attire, or mayoral robes. Secondly, and not to be regretted at all, the subject picture with a medical theme has disappeared. This is not an endorsement of the view that a picture should be without a story, a view that is flatly contradicted by some of the finest pictures in the world; it is a word of thanks for being spared the kind of medical story in paint that is designed to be moving, but which so

rarely moves. There is, however, in the exhibition one direct appeal to medicine—namely, that furnished by six works of the late Mr. Charles Sims, all of which may be termed experiments in colour thinking. Mystical but purposeful, orderly in their incoherence, and pathetic in their brave attempt to tell what cannot be told and to interpret what cannot be known, we are not surprised to hear that there was official reluctance to display them. If this is so the contrary decision is a matter of congratulation; it was inevitable that the obscurity of these pictures should deprive them of popular appeal, and perhaps inevitable that some should regard them as the fruits of an aberrant mind, but no student of mental science would endorse this view. It is noticeable that in connexion with Sims's fantasies references have been made in the lay press to the colouring and composition of the work of El Greco, to the themes and treatment in Blake's illustrations, and to the well-known allegorical pictures of Watts, some of which can be seen in the Tate Gallery. It may be that these references were dictated with some idea of reconciling the work of Sims with that of more comprehensible but comparable artists, yet a large school of modern neurologists would not require to fall back upon any such matter-of-fact explanation as a proof of the sanity of these pictures. Whether Sims is able to communicate through his canvasses the thoughts that inspired him must depend upon the receptivity of the spectator, but his lovely attempts to do so merit admiration and sympathy.

THE CONTINENTAL ANGLO-AMERICAN MEDICAL ASSOCIATION.

IN our news columns appears a report of the first meeting of the Continental Anglo-American Medical Association which has been held since 1914. This Association was founded in 1889 to serve as a bond of union between British and American practitioners on the Continent of Europe and in Northern Africa, with the further object of furnishing useful information to the travelling public. For many years before the war the Association played its rôle in both respects; the membership was then about 125, whose names, addresses, and consulting hours appeared on a leaflet issued periodically as a directory by the Association. An annual dinner was arranged in Paris and the list of members enabled scattered practitioners to keep in touch with each other, especially with a view of knowing to whose care patients might be safely recommended when changing from one foreign resort to another. Five years ago, when the question of formal dissolution came up, we confessed to a sympathy with the minority who desired continuance, and expressed a feeling that if this minority chose to form the nucleus the opportunity of further association would arise. We are happy to see that this has now come about, and we warmly commend the Association to all English-speaking practitioners abroad. At present the names of those practising in Switzerland do not appear on the list.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, May 22nd, when Sir Donald MacAlister, the President, will take the chair and give an address. The Council will continue to sit from day to day until the termination of their business.

Dr. R. King Brown, for 27 years medical officer of health for Bermondsey, is shortly to retire owing to ill-health.

THE voluntary hospitals have lost a good friend in Sir John Craggs, whose death in his seventy-third year occurred on May 2nd. A chartered accountant of high standing and a member of the Council of the Institute, he placed his services without reserve at the disposal of the Council of King Edward's Hospital Fund, was one of its honorary secretaries for a period of ten years (1897–1906), and was then elected to its Council. His book on Rate-supported *versus* Voluntary Hospitals may still be read with benefit by any who are studying the intricacies of a many-sided problem; his own conclusion was that in almost every respect the voluntary system scores in economy and efficiency. Sir John Craggs was especially interested in researches into tropical medicine. He was vice-president of the Seamen's Hospital Society for 26 years, and his benefactions to the London School of Tropical Medicine included a travelling scholarship and a substantial annual prize. He financed the antimalarial investigation carried out on the Roman Campagna.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXV.—TREATMENT OF RICKETS.

II. CURATIVE MEASURES.*

THE child who has developed rickets may be in apparently good general health and evidence of the disease may only be discovered on careful examination, or he may show all the classical signs of an advanced case. If treatment can be applied in the early stages, it is usually possible to remove all evidence of disease within a few months, but if severe deformities have occurred, they will persist long after the active stage is passed and possibly throughout life. If this is explained to mothers, even those whose coöperation is not readily given will generally try to ensure sufficient treatment for the child.

Treatment of the General Health.

Most rachitic children require treatment of the general health as well as treatment of the rachitic process itself, and the bone lesions are frequently "healed"—i.e., the bones and osteoid tissues are satisfactorily calcified—some time before the general health reaches normal. Treatment of the general health usually includes adjustment of the diet, since in these cases there has often been much dietetic mismanagement. After the age of weaning I usually advise the inclusion in the diet of one pint of cow's milk daily, three to five eggs weekly, and from the age of 12 months, meat also on three to seven days in the week. Outdoor life usually brings about an improvement in general health, in contentment, activity, and appetite, which can seldom be attained without it. In summer it will bring about healing of the bone lesions in all cases, but if the exposure to sunlight is scant healing may be slow unless other treatment is also given. Other means of improving the general health frequently include the provision of proper hours of sleep, suitable clothing, and, if possible, massage, but these are not directly curative of rickets.

Treatment of the Defective Calcium-phosphorus Metabolism and so of the Rachitic Bone Lesions.

The defective calcification of the bones is part of the active process of rickets—i.e., of the disturbed calcium-phosphorus metabolism. To renew normal calcium deposition in the bones we supply vitamin D in liberal amount, and this can either be given by mouth or be formed in the skin by exposure of the patient to ultra-violet light. Healing of the bone lesions usually proceeds at the same rate, whether the vitamin is provided by cod-liver oil administration or by artificial ultra-violet light therapy, or by exposure to sunlight. I have the impression that if the child does not get out of doors artificial light therapy produces greater improvement in the general health than does cod-liver oil alone. Cod-liver oil,

* Part I., dealing with Prophylaxis, appeared in THE LANCET last week.

begun gradually, can be used in double or more than double the prophylactic dose, say 1 to 1½ drachms of a 50 per cent. emulsion, or for an older child 1½ to 2 drachms of cod-liver oil and malt, three times daily. With adequate treatment an X ray plate of the long bones usually shows evidence of calcification of the osteoid tissue in 10 to 21 days, and calcification is complete in times varying from one month in very slight cases to perhaps four months or longer in severe cases, but, of course, rachitic deformities may persist for years or even throughout life. There is no evidence that more rapid effects can be brought about by the use of concentrated preparations of vitamin D, but when more is known as to suitable dosage these should prove a definite asset in the treatment of older children who dislike cod-liver oil or in infants with enteritis or digestive disturbance.

The Prevention of Bone Deformity.

Until the bone lesions are healed—i.e., until the bones are properly calcified—steps should be taken to avoid the production of any fresh bone deformities. Thus unless proper support is given to the back a chest sulcus may be increased by the child having a pillow under its head, or by its sitting in a hunched-up position with the back curved. Curvature of the bones of the lower limbs is often increased by bearing the weight of the body, and, in order to prevent this, all children able to stand should have a light straight splint, projecting several inches beyond the foot, applied to the outer side of the leg. This should be removed at night, or at other times when the child is not likely to try to stand, and only applied with the object of preventing standing while the bones are abnormally soft. The purpose of the splint should be explained to the mother. As soon as the X ray plate shows calcification to be nearly complete the splints can be discarded. If no radiograms can be obtained, splinting should be continued for, say, one and a half to four months after the beginning of treatment, according to the severity of the case, but the period is a matter of guesswork if no plate is available. If the case is only seen at the end of the summer, healing will probably be already advanced or possibly complete. There is one small point which may be helpful in such cases—if the costochondral junctions are of normal size while enlarged epiphyses and bending of the long bones are still present, this suggests that healing is complete—since a rachitic rosary disappears under treatment more quickly than enlarged wrist epiphyses—and in such cases it is unnecessary to prevent the child standing.

Orthopædic Treatment.

Three stages of the disease have been mentioned: the *active stage* of disturbed calcium-phosphorus metabolism and deficient deposition of calcium salts in the growing bones; the *healing stage* during which the blood-calcium and blood-phosphorus return to normal and calcium salts are laid down in the osteoid tissue of the bones as well as at their growing ends; and the *healed stage* at which the bones are fully calcified, but deformities may still persist though the bones tend steadily to recover normal shape. Provided no recurrence of rickets takes place the amount of improvement which may occur in bent long bones in the course of one to two years is remarkable, and except in cases of severe deformity operative treatment is undesirable before there has been time to observe what improvement is occurring as the result of growth. In many cases it finally proves unnecessary, even when the initial deformity was considerable. If special appliances are required—e.g., on account of knock-knees and lax ligaments at the knee-joint—the advice of an orthopædic surgeon should be obtained.

Treatment of Rickets Associated with Other Diseases.

There are certain diseases with which rickets is commonly associated. Spasmophilia is nearly always accompanied by rickets; in fact, it may be regarded as part of the symptom-complex of rickets associated with low blood-calcium instead of with low blood-phosphorus, the common form; hence antirachitic treatment should be given to all such cases, together with special treatment for any urgent symptoms such as convulsions or laryngospasm. The administration of calcium chloride, the drug most commonly used for rapid control of the symptoms of spasmophilia, does not *cure* the disease, and the child should be kept under observation until it has had an adequate period of antirachitic treatment.

Many cases of rickets first come under observation for bronchitis or other respiratory affections to which such children are particularly susceptible, and care should be taken to look for evidence of the underlying cause in such cases and to give specific antirachitic treatment whenever the presence of rickets cannot be excluded. Infants and young children with scurvy not infrequently show evidence of other dietetic errors, and as in both rickets and scurvy there is enlargement of the rosary and of the epiphyses, it is frequently difficult to be sure whether one is dealing with scurvy alone or with scurvy and rickets—hence it is as well to give a liberal supply of both vitamin D and C in such cases. In cases of chronic intestinal indigestion or of cœliac disease with defective absorption of fat, cod-liver oil is not a suitable agent for prophylaxis or cure of associated rickets, and in such cases a concentrated vitamin D preparation (not in oil) or light therapy is indicated.

There is a close association between nephritis in infancy and early childhood and the development of rickets, and authorities are not agreed as to whether the bone changes which are associated with renal disease differ in any essentials from ordinary rickets. The bone lesions of some at least of these cases respond to ordinary antirachitic treatment. The possibility of renal disease should therefore be especially borne in mind in every undersized child with severe rickets and in every case of rickets in a child over, say, 2½ years; and all young children with chronic renal disease should receive regular antirachitic treatment, probably both in winter and in summer.

HELEN M. M. MACKAY, M.D., M.R.C.P. Lond.,
Physician to the Queen's Hospital for Children.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

THE King has approved of the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surg. Comdr. T. B. Dixon.

ROYAL ARMY MEDICAL CORPS.

Maj. J. du P. Langrishe retires on retd. pay and is granted the rank of Lt.-Col.

Capt. P. R. O'R. Phillips to be Maj. (Prov.).

ARMY RESERVE OF OFFICERS.

Lt.-Col. B. A. Craig, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

MILITIA.

Maj. W. A. Lethem resigns his commn.

TERRITORIAL ARMY.

Lt. O. G. Misquith to be Capt.

Lt. D. R. McGregor is secd.

Lt. N. F. C. Burgess, from supern. for serv. with Univ. of Lond. Contgt., Sen. Div., O.T.C., to be Lt.

A. Bowie to be Lt.

ROYAL AIR FORCE.

Flight Lt. T. K. Place is promoted to the rank of Squadron Leader (Dental) on promotion to Major in the Army Dental Corps.

RESERVE OF AIR FORCE OFFICERS.

F. G. Mogg is granted a commission in Class DD as a Flying Officer.

INDIAN MEDICAL SERVICE.

Temp. Lt. Bhagwant Kishore Sikand to be Temp. Capt.

Special Articles.

CONFERENCE ON RHEUMATIC DISEASES.

BATH, MAY 10TH–11TH.

THE Conference on Rheumatic Diseases now being held in Bath was opened on Thursday, May 10th, by Sir GEORGE NEWMAN, the President, who said:—

In the sixteenth century the Englishman was called a "sweater" because of the four or five strange epidemics of *sweating sickness* which began about 1485 and continued intermittently until 1551 and which it was alleged had been introduced from abroad. In the eighteenth century we were described as "tipplers" because of our alcoholic habit of excessive spirit drinking, and as a "pock-marked" people because of the wide prevalence of *small-pox*. In the nineteenth century we became notorious as a people who were the victims of *rickets*, *gout*, and *tuberculosis*. Now we are chastised with *rheumatism*. In this dark record there is, however, a bright ray of light. Sweating sickness, as such, has vanished; excessive addiction to strong and raw spirits is a thing of the past; no one need now have small-pox unless he wishes to have it; it is known that severe rickets and gout can be readily prevented; and the mortality of tuberculosis of the lung is less than a quarter of what it was in 1847. In a word, we have in one way or another found the answer to these six scourges, each of which threatened to be formidable in its day. They have been conquered, or at least can be conquered if and when we so desire.

The Problem.

We are met to-day to consider the nature of the campaign which should be organised if we would similarly control rheumatism. There can be no doubt as to the urgency of the matter, which has been made manifest: (1) by the advance in our knowledge of the heterogeneous group of morbid joint conditions; and (2) by the data furnished to us for the first time by the school medical service and the health insurance system. We now know that acute rheumatism of children is sowing seeds of a growing harvest of disease of the heart and nervous system; and secondly, we now know that the chronic forms of rheumatism are very seriously crippling many hundreds of thousands of our people, who are not only thus subjected to suffering and disablement, but are losing heavily both in time and money. This disease is now recognised to be every year a drag on industry, an evil incubus on the worker, a source of oppressive financial loss to the State, and a protean cause of excessive mortality and ill-health. We are all here because we are deeply convinced that there is need for coördinated action for the thorough and continuous investigation of this malady in all its forms, and then for a well-devised and systematic attack upon it. Coöperation will take different, though converging, paths, for though the problem is one in issue, it is manifold in aspect.

The Chief Medical Difficulties.

Our main difficulties are three. First, we cannot yet exactly define the respective relation of the varied forms of rheumatism to each other, nor their distribution over the world generally or in our own country; secondly, we do not know with certainty the *causa causans* of this morbid group, though we are learning to circumscribe and differentiate their predisposing conditions; and thirdly, our varied medical experience is not yet in working accord as to the best means of treatment. No doubt some of the divergence of view as to treatment is due to the lack of what the engineers call "assembly of parts," and some to the fact that new methods of investigation and of physico-therapeutics are of recent invention or application. What is needed, in fact, is the assembly of all the parts, the unification and harmonising of all the experience available—experimental, clinical, and therapeutic. Hopeful advances are being made in all three directions but they await *integration*. For instance, in treatment, some swear by light and heat, others would be saved by water; some swear by massage and manipulation, others by rest; and some, rightly enough, do not swear at all, but proceed from case to case with tentative empiricism.

We must not forget that medicine has often enough won its way by empirical methods and the evidence of circumstance. The validity of vaccination as protective against small-pox was established by Jenner in 1798, though the infective cause of the disease was unknown and, what is rather strange and surprising, remains unknown to-day. Enteric fever was both controlled and successfully treated long before the bacillus was isolated by Eberth and Gaffky in 1884. Typhus fever was likewise conquered though its cause had not been elucidated. Koch discovered the bacillus of tuberculosis in 1882, but the disease was successfully treated and had begun to decline 40 years earlier. The history of the pathology and prophylaxis of these four diseases is deeply instructive, and I commend a consideration of it to all students of medical progress. There is perhaps a tendency at the present time for persons blessed with the faculty of curiosity but not with the virtue of circumspection to plunge into the study and treatment of disease with insufficient regard to the history of man's growing control of morbid processes, a control exercised primarily through a wider understanding of physiology and pathology.

Acute Rheumatism.

We now know that acute rheumatism begins as a disease of school age (5–14), though not a disease spread by the elementary school. It is at school age, therefore, that we must first both explore and prevent. We must explore the obscure signs of invasion; we must prevent the subsequent *polyarthritis*, *carditis*, and *chorea*. It is estimated that this infection is responsible for 80 per cent. of the deaths from heart disease under 20 years of age and 40 per cent. of the total cardiac mortality, itself the principal certified cause of death in England.

The cause of the disease is not yet fully proved, but the hypothesis which at present holds the field is that acute rheumatism is the reaction of the human body to the presence of the *Streptococcus viridans*. This organism is widely distributed, is frequently found as a harmless saprophyte, or as the causal agent in lesions which have nothing to do with rheumatic fever. If it be, as is believed, a common, perhaps a constant, habitant of the body, we must concentrate our attention on the conditions, circumstances, or predispositions, external or internal, which induce it to assume an activity which results in rheumatic fever. It would appear to be as futile to attempt to annihilate this streptococcus as it would be to exterminate the bacillus of tuberculosis. In our attack upon either of these diseases we must direct our main efforts to the fortification of the human body, to the exclusion from it of the invading micro-organism, or to the frustration of the activities of the micro-organism within the human body. This largely resolves itself into a question of those social conditions of the child which lead to rheumatic infection. Sometimes it may be coldness or chill in susceptible children, a damp house, or inadequate and unsustaining food, or unsuitable clothing, boots and shoes, or "feckless" mothering. To discover that a certain percentage of rheumatic children hail from "damp" houses—an elusive character of house property to measure—is not necessarily to discover a primary predisposition, for many other such cases come from dry houses, and after all a large majority of non-rheumatic children in any given district may also live in "damp" houses. Damp houses are no doubt undesirable, but living in damp houses does not, of itself, produce acute rheumatism. There are more damp houses in rural than in urban districts, yet the disease is ascertained proportionately to be more incidental in urban areas. It is the *total social, domestic, and physical upbringing of the child* which

seems to be the common denominator. For this is what affects the constitution of the child in the long run, which tends to make its tonsils and lymphoid tissue receptive rather than resistant, which gives us in a word a *susceptible* child, or which favours the development of infection within its body. Therefore, closer supervision by parents and teachers should be exercised over all children under the age of 14, in order to detect the earliest signs of rheumatic infection —"growing pains," nervousness and twitchings, repeated tonsillitis or chronic sore-throat, pallor and shortness of breath, and dental sepsis, which may be indicative of the liability to, or even the onset of, rheumatic fever. Such conditions call for early detection and prompt treatment. We have many agencies now available for this purpose—infant welfare centres, school medical service, hospitals, the medical practitioner, and so forth, but we do not use them sufficiently for this specific object, nor do we coördinate them as fully as we ought.

Speaking broadly, therefore, we must seek steadily to improve the personal and environmental hygiene of childhood, we must exercise a closer and more vigilant supervision of these susceptible children by the infant welfare and school medical services, and we must organise our methods of diagnosis and treatment of those found to be suffering from the disease. Definite steps of this nature have recently been taken in America and also in this country (particularly at Birmingham, Bristol, London, Glasgow, and elsewhere, with 400–500 available beds).

The Rheumatism of the Adult.

When we turn to the rheumatism of the adult we find further confirmation of the need for organised, intensive, and comprehensive investigation, not only in the laboratory, but at the bedside, and even in the factory and workshop. As in acute rheumatism, so here, we need research into the social and causative aspects; we need to pool our experience of therapeutic measures. It is the integration and coördination of the immense stores of experience now being acquired which is the principal desideratum at the present time. Every medical practitioner can help in this field of study. If the holding of this conference encourages the whole profession to cease to work in water-tight compartments in this disease it will do great good. The consultant and the specialist should be invaluable to the public medical services, as they in their turn should serve him. Nor is medical coöperation our only need. There are many contributory public agencies in the State, and the time has come for them also to combine against this common enemy. The maternity and infant welfare services, the school medical service, the poor-law, national health insurance, the hospitals, and the voluntary health societies could render much assistance by addressing themselves to the solution of this problem which, like tuberculosis, has a very wide, almost a universal, social province.

In spite of the darkness which surrounds chronic rheumatism there is some brief general counsel which may be given to all persons suffering from any degree or form of chronic rheumatism. First, they should promptly seek medical advice for the discovery and removal of possible sources of infection in their own bodies, which are acting as generating centres of auto-infection—such as infection of the tonsils, teeth, nasal sinuses, and intestinal tract. Wherever the source of such infection may be, it is absolutely of paramount importance that it should be dealt with promptly and thoroughly. No effort should be spared to check it at its very earliest stage. It has been well said that it is "perfectly futile to waste valuable time by palliative treatment, with anti-rheumatic or other drugs, local applications to the joints, and so forth, till the focus of infection has been eradicated." A stitch in time saves nine. Secondly, persons suffering from rheumatism should so order their lives as day by day to practise personal hygiene, and strict *moderation* and selection in food and drink, exercise, fresh air, and rest. Thirdly, they should be vigilant to avoid any predisposing conditions which conduce them to attacks of the disease, such as dampness and chill, unsuitable clothing, excessive use, misuse, or disuse of the stricken joints, or a clogged alimentary system. Neglect in the early stages of their condition is their supreme danger.

We have the exceptional advantage of the counsel of my distinguished colleagues, Lord Dawson of Penn, and the two Regius professors from Oxford and Cambridge, Sir Farquhar Buzzard and Sir Humphry Rolleston. We have also a brilliant group of recognised medical authorities, including those whom it is a pleasure to welcome to our shores. Further, it is particularly agreeable to confer with the physicians of this city, whose work and writings have contributed so largely to knowledge and practice. We cannot hope that our conference will furnish a complete answer to all our questionings and difficulties. But it should stimulate us in coöperation and endeavour, and it should guide us in the direction of a fuller and a more scientific study of what Milton and Dryden called the "bone-racking" disease. Whatever befall us in this enterprise we are fortunate in finding ourselves in the beautiful and ancient city of Bath, engaged, like the Romans and our own forefathers, in the rediscovery of its healing powers.

ROYAL COLLEGE OF PHYSICIANS OF LONDON:

THE HARVEY TERCENTENARY.

THE tercentenary celebration of the publication of the "De Motu Cordis" by William Harvey has been arranged for May 14th–18th, and the full programme will be found in THE LANCET of March 24th (p. 621).

Demonstrations at University College.

Fuller details are now available as to the demonstrations to be delivered at University College on Tuesday, May 15th, and Wednesday the 16th.

At 10.30 A.M., there will be an Exhibition of a Film of Harvey's Experiments, prepared by Sir Thomas Lewis and Dr. H. H. Dale.

At 11.30 A.M., the following demonstrations will be given:—

1. Prof. Lovatt Evans and Prof. E. B. Verney will give a demonstration of the Isolated Mammalian Heart-lung Preparation. The preparation to be shown is one devised by the late Prof. E. H. Starling for the purpose of studying the reactions of the mammalian heart to measurable changes in the conditions under which it is working. The heart and lungs are completely isolated from the rest of the animal, the normal peripheral circulation being replaced by a system of tubes representing its arterial, capillary, and venous components. The rate of inflow of blood into the right auricle, the temperature and composition of this blood as well as the peripheral resistance against which the left ventricle works can be varied and measured at will. Further, the effect of variations in any of these factors on the volume of the heart, on its rate of beating, and on the coronary flow may readily be studied.

The demonstration is designed primarily to show the nature of the reaction of the isolated heart to changes in the work which it is called upon to perform. These changes in work are here brought about by variations in the venous inflow or the peripheral resistance or in both. The effect of changes in the CO_2 tension in the gas ventilating the lungs, and of the addition of adrenalin to the circulating blood will also be shown.

2. Dr. H. H. Dale will demonstrate an apparatus for artificial circulation, designed by Dr. E. H. J. Schuster and himself, and consisting of two diaphragm-pumps, the throws of which are independently adjustable while the machine is in action. The two pumps are made to replace the two ventricles of the heart, so that the reactions of the blood-vessels of both major and minor circulations, and the resulting changes in resistance and in distribution of the blood in the system can be studied, free from the complications of compensatory or other changes in the action of the living heart. One pump carries out

ıe circulation through the lungs, the other through ıe whole, or any selected part of the systemic circulaon. This system, with its artificial heart and natural ːsistances, is in some sense a counterpart of the eart-lung preparation.

3. Sir Arthur Keith will demonstrate: (*a*) models ıade in 1906 to illustrate the movements of the ıman heart and to explain the negative wave in the ıgular pulse; (*b*) Sir James Mackenzie's original olygraph preserved in the Museum of the Royal ollege of Surgeons; and (*c*) will give a brief account f the anatomical examination of hearts observed and ːcorded by Sir James Mackenzie during his practice ı Burnley.

4. Sir Thomas Lewis will demonstrate, with the ılp of Dr. Ronald Grant and Dr. K. E. Harris, some ːactions of the human skin to stimulation, illustrating ɔntraction of the minute vessels and their reactions ɔ injury. This demonstration will be given on Vednesday only at 11.30 A.M.

5. Dr. B. W. S. Mackenzie will show some of ir James Mackenzie's original apparatus.

There are still some tickets available for thes◦ ːmonstrations, and medical practitioners who desire ɔ be present should apply for them at once to the ːgistrar, Royal College of Physicians of London, all Mall East, S.W. 1.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Research in India.

MEDICAL research and education are receiving much ɔnsideration in India at the present moment. A ɔmmittee presided over by Sir Walter Fletcher, ːcretary to the Medical Research Council, has just ispersed after three strenuous months' work. The romotion of medical research is officially under the ɔntrol and guidance of the Government of India. [uch research work, however, is carried out in rovincial institutions, and it was felt that the time ad come when some definite scheme for the promotion f research should be formed, outlining work to be ırried on by the Central Government and correlating ıe efforts now being made in existing provincial ıstitutions such as the Calcutta School of Tropical [edicine. The report of the committee is confidential nd may never be made public, but it is rumoured ıat the research department will be greatly ːengthened and augmented and that a new special ːntral research institute may be created. Sir Walter letcher's large experience was enlisted to help the overnment of India and the Indian Research und Association to organise means whereby medical ːsearch will be fostered and encouraged, for at present ıe valuable material available is not being used to ıe best advantage.

Sanitation in Bengal.

It has usually been held that the main stream of he Ganges used to flow southwards past Calcutta in he Hooghly and that a sudden diversion eastwards ɔme centuries ago carried away the Ganges flood ːater, bereft Central Bengal of its agricultural rosperity, and turned healthy tracts into what are ow the most malarious districts in the plains of ndia. Sir William Willcocks, the irrigation expert ho has been touring the delta of Bengal, in a ːcture to the British India Association, combats this iew; he holds that the main Ganges, by reason of s size, could never have been retained in the Iooghly and other channels, but that the present ːaterways in Western and Central Bengal are old anals made by "Bhagirath," the legendary chieftain ho conducted the Ganges to the ocean in order to ːrigate these tracts with Ganges flood water. The ːresent stagnant condition of the waterways is due ɔ centuries of neglect and the remedy lies in their leaning and re-excavation. They could again be ıed as water channels if a barrage were made across the Ganges at a suitable place, and the surrounding districts now desolate and malarious would become prosperous and healthy. Whether or not any practical scheme can be devised on these lines will have to be considered. On other lines Bengal is striving to improve health conditions. The province is adopting the "thana," covering an extent of about 80 square miles as the sanitary unit area. Each area is to be provided with at least one sanitary officer, either a sanitary inspector or a doctor. This officer will deal with preventive measures in his unit guided by the superior health staff of the district, who may when necessary concentrate all his forces in one part of the district. It is hoped that better results will ensue from this rearrangement.

Maternity and Child Welfare.

The more social aspects of medicine are gradually developing in India, though but slowly. Centuries of the feudal and family outlook have restricted the charitable impulses of the Indian to his own family or class. The community as a whole is still slow to believe in movements of a general nature such as maternity and child welfare and the protection of child life. Nevertheless, the maternity and child welfare movement since its inception by Lady Chelmsford has progressed considerably and the series of health and welfare exhibits held throughout India during the past cold weather have inspired workers to continue their efforts. The Child Marriage Bill and the Remarriage of Hindu Widows Bill have been again before the Central Legislative Assembly and show that the desire of the educated classes to break through the barriers of traditions and customs which oppose progress are becoming more and more capable of formulation and public discussion. In the Bill presented to the legislature it is proposed to raise the marriageable age of girls to 14 and of boys to 18.

Scavenging and Sewerage.

The "sweeper" or scavenger is one of the most valuable persons in India—only one or two of the largest cities have sewerage systems and even in them a large portion is unprovided with water-closets. So valuable is the sweeper that he is usually known by the honorific title of "Maharaj." It recalls the telegram during the war by an anxious sanitary commissioner in Mesopotamia to headquarters: "Will exchange medical officers at the rate of two for one sweeper." Both Madras and Calcutta have lately suffered from sweepers' strikes, and the sanitary (or insanitary) consequences are appalling. The recommendation of the Royal Commission of 1840 that excreta should be removed as quickly as possible from human habitation and preferably by means of water carriage is still unfulfilled even in large cities.

Improvement in Longevity Rate.

An interesting sidelight is shown on the improvement of health conditions in India by the report of the actuary of the Government of India on Indian insurance companies. In the statistical study of rates of premiums and the duration of assurance membership he concludes that there has been a distinct improvement in the longevity of the Indian population during the last 30 years.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Experiments on Children.

A PUBLIC sensation has been created here by a report of some experiments on the cure of rickets, published by Dr. Vollmer, of the Infants Hospital. In order to prove that a proprietary preparation of irradiated ergosterol was efficacious even under the most unfavourable general conditions, the investigators kept 20 infants in dark rooms and gave them a diet poor in vitamins but supplemented by this preparation. The report contained a somewhat unfortunate sentence in which Dr. Vollmer explained

that he had performed his experiments on 100 rats and 20 children. The result was that a medical member of the Reichstag, Dr. Moses, asked the Minister of the Interior whether he would take measures to stop experiments of this kind. He mentioned similar reports in the medical press of experiments on children suffering from tuberculosis and scarlet fever. The President of the Health Office replied for the Government that he was informed that the report meant that the children had not received a special antirachitic diet, nor any actinic rays whilst under observation, but apart from this they had been treated like other children. They had, moreover, been cured, and the supposition that they had been damaged by their stay in the hospital was therefore erroneous. Concerning the other facts mentioned by Dr. Moses, he had not yet made full investigation, but he was in a position to state that some of them did not even refer to Germany, but to foreign countries. The question has also been discussed in the Berlin Medical Chamber, and a committee has been elected to inquire whether Dr. Vollmer and his colleagues have contravened the rules of medical ethics.

Payment of Medical Deputies.

Medicine has but few representatives in the German Parliament, compared with the legal, the clerical, and other liberal professions; in the discussion of Bills which deeply affect its interests, it is represented quite inadequately. The reason is that the prolonged absence from home connected with membership of Parliament involves the loss of practice—a loss for which the salary of a deputy does not fully compensate. The Leipziger Verband has therefore decided to accumulate a Parliamentary fund by imposing an extra levy of M.20 (£1) on each member. The amount thus raised should be £40,000, which will be used to indemnify medical deputies for the loss of practice during their absence for Parliamentary work. No individual party is to be supported; the only condition is that deputies have to work for the profession —i.e., to vote against any Bill which may be prejudicial to its interest. A committee of four members of the Leipziger Verband will be entrusted to allot the money. The proposal has provoked a great deal of opposition and several local branches have protested, saying that the subscription to the Leipziger Verband is already too high, and that more cannot be contributed in the present sad condition of the profession. They also suggest that it is unconstitutional to bind Members of Parliament in their votes by giving them money on conditions.

Responsibilities of Pharmacists.

The provisions of the German law concerning the abuse of morphia and cocaine are somewhat severe. The Supreme Court at Leipzig recently gave judgment that a licensed chemist is liable to punishment if he dispenses a medical prescription although aware that the drug is destined not for medical purposes but for abuse. If he acts bona fide he is not held responsible, and the liability to punishment rests on the medical man who has prescribed the drug. This remarkable ruling requires that the chemist shall ascertain whether a prescription is made for curative purposes, in this way exercising a certain amount of supervision over the practice of individual medical men. The Chamber of Chemists, the official representative of the pharmaceutical profession, has energetically protested against the above judgment, declaring that the chemist cannot but execute every prescription signed by a duly qualified medical man and that an obligation to control the object of a prescription would be ultra vires. The Medical Chambers have not yet dealt with the matter although it has already been discussed in the medical press.

As diphtheria is spreading and is growing more malignant in Berlin, the municipal authorities have decided that children of from 1 to 6 years of age may be inoculated by the Schick method free of charge. There is, of course, no compulsion, but it is explained to the public that such inoculation may be expected to protect children against the disease for at least seven years.

Dr. Reyer lately read before the Berlin Society for Internal Medicine a paper on mediastinal pleurisy. He has seen 26 cases occurring as a sequel to influenza and sore-throat. The symptoms are severe attacks of cough and dyspnœa, with very few signs on auscultation. Percussion reveals a triangular patch of dullness in connexion with the normal heart dullness. Apart from this sign the diagnosis can be established by radiography. The prognosis is not a bad one.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Retirement of Prof. J. A. Lindsay.

Prof. J. A. Lindsay, Emeritus Professor of Medicine in the Queen's University of Belfast, has decided to retire from active practice and to reside in London. At a farewell dinner on April 24th many of his medical friends took the opportunity of expressing their high appreciation of his public services to the hospitals and university, of their indebtedness to him as a clinical teacher, and of their affection for him as a colleague.

Mr. T. S. Kirk, chairman of the medical staff of the Royal Victoria Hospital, in proposing Prof. Lindsay's health, paid a graceful tribute to his long and valued connexion with the hospital, first as a physician, and later as a chairman of the board of management. He had given his time ungrudgingly to further every interest of the institution. Prof. C. G. Lowry, chairman of the staff of the Belfast Maternity Hospital, associated himself with Mr. Kirk in this toast, stating that there were many criteria by which success in life could be judged, but if Prof. Lindsay valued renown as a clinical teacher, and the gratitude, affection, and respect of the many generations of medical students whom he had taught, he might be deemed to have achieved success in no ordinary measure. Prof. Lowry also paid tribute to his other services to the school, especially referring to the establishment of the Dental Faculty, and to his strenuous activities for the amalgamation of the Royal Victoria Hospital and the New Maternity Hospital, activities now crowned with success.

In his reply, Prof. Lindsay said that teaching, especially clinical teaching, had always been a joy to him, and he was never happier than when surrounded at the bedside by a group of eager and intelligent students. The late Sir William Osler once said that he wished his epitaph to be "he taught students in the wards." He himself would desire no better epitaph. After a brief glance at the progress of medical science in recent years, he sketched the progress of the Belfast Medical School within his own time. The old Royal Hospital had had 200 beds with a staff of 11, only one theatre, and two special departments. The present Royal Victoria Hospital had 436 beds, a staff (including the auxiliary staff) of 53, 9 theatres, and 6 special departments. These figures gave the measure of the progress of the times. It was about to add a maternity department and a department for paying patients. He had many regrets on leaving Belfast, but he felt that after 44 years of practice he might fairly take off his harness. He intended for the present to retain his seat on the Senate of their University, and would watch the further progress of the School with which he had been so long associated, and for which he predicted a bright and successful future.

Later in the evening speeches stressing the varied nature of Prof. Lindsay's active life in Belfast were made by Dr. J. S. Morrow, Prof. W. St. Clair Symmers, Prof. R. J. Johnstone, Prof. T. Sinclair, Sir John Campbell, Prof. A. Fullerton, Prof. W. W. D. Thomson, Dr. J. C. Rankin, Dr. Gardner Robb, and Sir Thomas Houston.

McKisack Memorial Fund.

A meeting of the subscribers to the McKisack Fund for a memorial to the late Dr. H. L. McKisack will be held at 10.30 A.M. on May 17th in the Royal Victoria Hospital, Belfast, immediately before the clinical meeting of the Ulster Branch of the B.M.A., to decide what form the memorial should take. It is hoped that intending subscribers will send their subscriptions to Mr. Edwin Hill, Northern Bank, Belfast, or Mr. Stanley Ferguson, Ulster Bank, Belfast, before this date in order that the subscription list may be finally closed.

MEDICINE AND THE LAW.

Coroner and Medical Practitioner.

AT a Greenwich inquest held at the end of April the coroner severely criticised a medical practitioner for having been present without consent at a post-mortem examination upon a man who died while entering an omnibus. The practitioner was apparently acting as consultant to the London General Omnibus Company which was interested in view of the prospect of civil proceedings in which it might be held liable. The coroner is reported by the *Daily Express* to have told the representative of the omnibus company that, if the company did things like that, he would shut them out of the court entirely; he was willing to give them every facility but he could not have such things done without his permission; "it is an unusual thing to do and is only worthy of a second- or third-rate insurance company." "The doctor," the coroner is reported to have added, "ought to know that he had no right to be present without the consent of the coroner." The gravamen of this medical practitioner's offence was presumably that, being a prospective expert witness and adviser employed by one of the parties to a prospective civil action, he acted improperly in being present at a post-mortem examination at which the other side was not similarly represented. It was presumably not suggested that a practitioner thus present without consent would abuse the occasion by attempting to fabricate or tamper with evidence; but he secured an advantage for his own side over the other side in having access to information and in having facilities which the other side was (for want of means or opportunity) denied.

At some stage of the inquest the coroner appears also to have said "I will see that the doctor is never present in my court on any future occasion." This, if correctly reported, raises interesting issues. There is doubt how far the proceedings at an inquest are entirely open to the public to attend. Particular circumstances may justify a private hearing, and a person whose behaviour is disorderly may certainly be excluded. The public, however, would probably be surprised to find that a coroner's court was so proprietary an institution that particular persons could be permanently black-listed. The omnibus company would naturally not tender any witness who was known to be unacceptable to the court, and the court has means of securing its own expert witnesses if expert evidence is deemed necessary; nevertheless it would be an unusual judicial utterance to announce that under no circumstances would a particular witness be allowed to give evidence at any inquest. A coroner, of course, can conduct his proceedings unaided. He summons the witnesses and, unless he otherwise permits, he examines them. He is a law unto himself except that the rejection of evidence is one of the grounds on which the High Court will interfere to quash the inquisition. But the present arrangement whereby parties are usually allowed to be legally represented and to offer evidence is worth preserving. The relatives of the deceased, for example, may often desire to tender medical evidence on issues such as insanity. It would be unfortunate if the more anachronistic features of the coroner's inquest were emphasised by too sweeping an assertion of them.

Effect of Illness upon Promise to Marry.

In a breach of promise action tried before Mr. Justice Acton last week, the defendant admitted his promise to marry the plaintiff but pleaded that his refusal to carry it out was justified by the fact that she had contracted tuberculosis. The plaintiff said the defendant knew quite well what her state of health was; she said she was now entirely recovered, and she suggested that the reason for the defendant's conduct was not her own health but another woman's attractions. The judge told the jury that there was no legal reason why a man should not be bound to marry a deaf-mute or a cripple provided that he knew of her affliction at the time he made his promise and that she agreed notwithstanding her disability. On the other hand, the man might be excused if the woman became thus afflicted after the date of the promise being made and before the date for its performance by marriage. The burden of proof would be upon the defendant to show that, after he gave his promise, there did supervene such a condition of bodily infirmity as would justify him in refusing to marry the plaintiff. Evidently the defendant failed to discharge this burden in the case recently tried, for the jury found for the plaintiff with £35 damages.

The law, it will be observed, concerns itself with the contractual, not with the eugenic, aspect. In the eighteenth century Lord Mansfield held that if, after a man had made a contract of marriage, the woman's character turned out to be different from what he had reason to think it, he could refuse to marry her without being liable to an action. As Lord Kenyon presently observed, whether the infirmity were bodily or mental, the reason was the same—it would be most mischievous to compel parties to marry who could never live happily together. But the text-books point out that a man cannot count on getting out of his promise to marry by disparaging himself—though the attempt is not uncommon. Some 70 years ago a man pleaded in a breach of promise action that, since his promise to marry, his lungs had become seriously affected, so that he was totally unfit for marriage. The judges heartlessly took the view that perhaps the lady might like to be his widow, and thus his plea failed.

False Description as Bachelor of Science.

A prosecution in Shropshire last week illustrated the ease with which unqualified persons can assert the possession of academic degrees. A school-teacher, describing himself as a Bachelor of Science of London University, was appointed to a post at a provincial grammar school in January, 1921. He proved to be an excellent teacher of mathematics and his degree was never questioned until last October, when the headmaster had to fill in the qualifications and service of his staff in connexion with the pension scheme for the information of the Board of Education. He found the claim to the degree to be unfounded, and he suspended the teacher, whom the school governors subsequently allowed to resign. The teacher has now been charged with obtaining money by false pretences from the governors of the school by falsely describing himself as Bachelor of Science of London. The magistrates took a lenient view and bound the accused over, subject to his paying £25 as compensation and £30 costs. The bench remarked, in conclusion, that greater care should have been taken in making the appointment. This presumably means that, if a university graduate applies for a post, his degrees should be strictly verified from the university calendar.

THE DEVONSHIRE AMBULANCE SERVICE. — The annual report of the Devon County Centre of the St. John Ambulance Association states that during the past year many new ambulance and nursing divisions were formed. During that period the three Plymouth stations alone made over 25,000 attendances in the case of accidents and fires, and the conveyance of crippled children and hospital out-patients. These figures are an increase of 800 per cent. over those of 1921–22.

Public Health Services.

A MEDICAL BENEFIT INQUIRY.

REMOVAL OF NAME FROM MEDICAL LIST: A QUESTION OF COSTS.

UPON a recent inquiry under Part VI. of the National Health Insurance Medical Benefit Regulations, the Minister of Health, after deciding to remove a doctor's name from the medical lists of the insurance committees concerned, made no direction as to costs. In this respect he followed the recommendation of the tribunal which, though of opinion that the complainant insurance committee was justified in preferring its representation against the medical practitioner, commented upon the fact that certain charges had not been substantiated. No proof had been adduced of three of the original charges, a fourth was not proved in substance, a fifth broke down for want of evidence, and a sixth was so extensively amended at the hearing as to amount to an entirely new charge. The tribunal found it impossible to ascertain how far the respondent practitioner had been put to expense in preparing to meet these particular allegations. The report upon the case expressly emphasises the desirability that representations under Part VI. should not be made to the Minister in such a form that at the hearing, apart from failure of substantiation upon actual evidence submitted, it becomes necessary to abandon charges without seeking to prove them. From this criticism the tribunal expressly excludes a case where failure of proof results from some unavoidable cause such as the death or other disability of proposed witnesses. The Minister's adoption of the tribunal's recommendation will be generally approved, but it would seem that, if the expense of preparing to rebut unproved charges could be ascertained, the doctor would be entitled to his costs in respect of those items in any event, whatever the general result of the investigation.

These cases turn upon their own special facts and are seldom of general interest. One charge in the recent inquiry may perhaps be mentioned. It was said that the respondent doctor, not being registered as a dental surgeon or being on the dental panel for insured persons, held himself out as a dental surgeon and acted as such to insured persons, and, when so acting, gave a full anæsthetic and charged both fees as if a doctor was also present, though in fact the respondent's wife was the only other person present. It appeared that the respondent, while previously employed as assistant medical officer of a certain Amalgamated Friendly Societies' Medical Association, had been allowed to do dental work. At the time of the dental operations mentioned in the charge, dental benefit had been recognised as an additional health insurance benefit by the approved societies of which the particular patients were members. He filled in dental letters with particulars of treatment, including a guinea for anæsthetist's fee, and he stamped his name and address on the letter with the description "dental surgeon." His defence was that, being a qualified medical practitioner, he could rightfully describe himself to insured persons as a dental surgeon; he further said he had never been informed that the effect of schemes for additional dental benefit would be to change the nature of his dental practice and to put him under restriction—e.g., as to charging for an anæsthetic in the absence of an assistant anæsthetist. The tribunal felt unable to accept the explanation of his alleged ignorance since the dental letters were clearly applicable only in the case of registered dentists. While no specific complaint of the actual treatment was received, the tribunal thought that both the patients and the societies were in fact deceived as to his right to receive reward for his services; the report regards his conduct in this matter as open to criticism and censure.

ULTRA-VIOLET LIGHT TREATMENT AT PUBLIC BATHS

In connexion with the proposal of the Manchester Corporation Baths Committee to instal apparatus for treatment by ultra-violet light at a cost of £400 at the Whitworth and Victoria baths, deputations from the committee visited Leeds, Bradford, and Stockport where such apparatus is installed in the public baths. They were informed that the innovation has proved a great success, the returns of attendances and the income from this source being as follows:—Leeds, from August, 1927, to February, 1928: total, 20,595; £1716 9*s.*; Bradford, from April 25th, 1927, to March 17th, 1928: total, 35,151, £2205 9*s.* 3*d.*; Stockport, from Feb. 15th, 1928, to March 24th, 1928: total 1503, £196 9*s.* 6*d.* There was no medical supervision whilst the treatment was given; permission from the Ministry of Health for the installation of the various appliances had not been asked. The medical officers of health of the three towns visited had raised no objections, and no complaint had been received of ill effects from the administration of the treatment.

The medical officer of health for Manchester, commenting on the visit, saw no reason to alter the views expressed by him two months ago, and quoted in THE LANCET of Feb. 25th last (p. 418). He does not approve of treatment by ultra-violet light in the absence of medical supervision either of the people treated or of the clinic itself; he has evidence that specialists in Manchester are constantly dealing with people who have suffered from undue exposure to ultra-violet rays, and serious conditions have been set up in these individuals as a result of unskilled treatment by this means. The only type of scheme which he can formally and personally approve is one which provides for the medical examination of all persons who are to be treated and the medical supervision of such persons at periods to be determined during the course of their treatment. The medical man or woman appointed for this purpose would possess knowledge and experience in the use of ultra-violet rays. No person should be admitted to the clinic unless passed by the doctor, and only such treatment should be given to any person as has been specially prescribed for him. In view of the strong opinion expressed by the medical officer of health the finance committee has recommended that the scheme proposed by the Baths Committee, which does not conform to these conditions, be not approved.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 28TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 376 (last week 326); scarlet fever, 1675; diphtheria 1055; enteric fever, 65; pneumonia, 1122; puerperal fever, 51; puerperal pyrexia, 115; cerebro-spinal fever, 9; acute poliomyelitis, 10; acute polio-encephalitis, 4; encephalitis lethargica, 37; continued fever, 2; dysentery, 24; ophthalmia neonatorum 123. No case of cholera, plague, or typhus fever was notified during the week.

Cases of small-pox were notified from the following 21 counties: London, 3; Chester, 2; Derby, 1; Durham, 92; Essex, 1; Gloucester, 1; Lancaster, 4; Leicester, 1; Lincoln, Parts of Kesteven, 4, Parts of Lindsey, 5; Norfolk, 4; Northumberland, 12; Nottingham, 15; Soke of Peterborough, 7; Stafford, 5; Surrey, 5; Warwick, 5; Yorks, North Riding 8, West Riding 10; Glamorgan, 18; Monmouth, 34.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on May 1st–2nd was as follows: Small-pox, 21 under treatment, 8 under observation; scarlet fever, 1588; diphtheria, 2200; enteric fever, 34; measles, 1379; whooping-cough, 150; puerperal fever, 18 (plus 13 babies); encephalitis lethargica, 6; "other diseases," 21. At St. Margaret's Hospital there were 13 cases of marasmus, and 11 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 (0) deaths from small-pox, 1 (0) from enteric fever, 117 (75) from measles, 5 (0)

om scarlet fever, 50 (13) from whooping-cough, (12) from diphtheria, 39 (6) from diphtheria and teritis under two years, and 80 (10) from influenza. ne figures in parentheses are those for London elf.

The two deaths provisionally classified to small-pox were signed to Gateshead. The fatal case of enteric fever tside London occurred at Norwich. Of the 42 fatal cases measles outside London, 4 were reported from Tottenham d 3 each from Liverpool and Salford; while the figures Edinburgh, Glasgow, and Dublin for the same week re 7, 3, and 3. Of the 37 fatal cases of whooping-cough tside London, 7 were reported from Liverpool, 4 from rdiff, and 3 each from Birmingham and Bradford.

e number of stillbirths registered during the week s 292 in the great towns, including 60 in London.

Correspondence.

"Audi alteram partem."

THE AUSCULTATORY GAP.

To the Editor of THE LANCET.

SIR,—Your annotation (p. 919) prompts me to w attention to a potential source of error in od pressure records to which I can find no reference standard literature. It is quite essential that the ssure in the cuff should be released slowly and h certain types of release valve this is a matter of ne difficulty. Even with the best type of valve ne inadvertence or distraction during the taking of ecord may result in a sudden drop of 20 mm. in ssure in the cuff. That sudden fall, though it y not bring the pressure down to the systolic level, ults in a sound heard by the stethoscope below cuff. It is an isolated sound, and though the ernal pressure be maintained at the level to which as thus fallen the sound is not repeated.

have detected this sound often enough to make curious as to its explanation. It is heard, under circumstances noted, before but not long before systolic pressure level has been reached and it is ilar in quality to the first sounds heard thereafter. occurs in the absence of extrasystole or of rnation of the pulse, and a sudden or at least id fall in the external pressure appears to be the ef factor in its production. An external pressure icient to obliterate the pulse wave in an artery s not necessarily inhibit all power of vibratory onse in the vessel wall and I can only think that sound is an expression of recoil. I am too little physicist to be clear in the matter.

I am, Sir, yours faithfully,

undee, May 4th, 1928. JAMES M. STALKER, M.B.

To the Editor of THE LANCET.

IR,—The suggestion in your very interesting otation that the "rapid" vibrations in the arterial l are responsible for any sound is, I venture to k, open to doubt, because unless those vibrations as many as 60 to 100 per second they are not likely produce any sound at all, much less the sound ciated with the estimation of the blood pressure. suggestion that eddies also play a part is open to ally strong objection, first of all because there is evidence whatever of such an eddy, and secondly ause no moving fluid, unless its surface be exposed air, can produce any sort of a sound.

I am, Sir, yours faithfully,

vansea, May 7th, 1928. G. ARBOUR STEPHENS.

To the Editor of THE LANCET.

IR,—May I draw attention to the theory suggested J. Barbier, in his monograph on "La Méthode cultatoire," to explain the mechanism of this nomenon. Barbier regards the gap as the acoustic equivalent of the anacrotic pulse and explains its occurrence by reference to the typical tracing of such a pulse. He points out that in the ascending limb of such a pulse curve there are three successive zones. Of these the first and third appear as more or less vertical lines, while the second or middle zone, which represents the anacrotic notch, appears as a horizontal line or plateau. If the armlet of a sphygmomanometer be applied and the pressure be raised to a point below the systolic level, the subjacent artery remains collapsed except when forced intermittently to open by the succession of pulse waves. When the armlet pressure is equivalent to a point either in the first or in the second zone of the pulse curve, the arterial door opens with a jerk, in response to a rapidly rising pressure, a percussing quality is imparted to the movement of the arterial wall and a sound is produced. On the other hand, when the armlet pressure is equivalent to a point in the second zone, the region of the anacrotic plateau, the arterial door is forced by a very slowly rising pressure and, therefore, it opens without clatter and no arterial sound is produced.

This explanation is so reasonable that we might accept it at any rate until a better one is forthcoming.

I am, Sir, yours faithfully,

Torquay, May 6th, 1928. PAUL C. GIBSON.

"THE GRATEFUL REPUBLIC."

To the Editor of THE LANCET.

SIR,—May I recall attention to the subject of invaliding from the Navy for tuberculosis, broached by an anonymous correspondent in your issue of April 14th? This subject was much discussed in the House of Commons in March last, when no one seemed sure how much tuberculosis there was in the Navy, and whether more or less than in the other Services or in civil life. The facts are uncertain, as the age distributions are unknown, but it may be well to state that in the last four years for which we have full figures, 1922–25, there averaged, from tuberculosis, per 1000, in the Navy (92,000 men), 2·0 invalids, and 0·3 deaths; in the Army (196,000 men), 1·2 invalids and 0·18 deaths; in the Air Force (30,000 men), 1·6 invalids and 0·14 deaths. Of the men in the Navy, 85 per cent.[1] are under 35, so it will be worth while to mention that in these same years, 1922–25, there averaged in England and Wales 6,000,000 male civilians, aged 15–35, of whom 1·15 per 1000 died of respiratory tuberculosis; and the total tuberculosis death-rate was 1·32. The annual loss or wastage from tuberculosis comes out, for the Army at 1·4, for the Navy at 2·3, for the Air Force at 1·7 per 1000. The simultaneous civil death-rate was 1·32. The average annual loss of men from tubercle in the three Services together in the four years was 476 invalided and 68 dead, 544 in all. Médecin-en-chef (Surgeon-Captain) Cazamian[2] tells us that there are fewer cases of tuberculosis in the British than in the French or the United States navies: Rho[3] says that from 1893–1920, only once, in 1906, had the Italian Navy fewer cases than the Army.

But what chiefly exercised the House of Commons was the question, what became of the 220 the Navy invalided in 1925 and how many of them got pensions, and how many should. It appeared that only 3 per cent. were pensioned in 1923–24–25, but more recently 10 per cent. Men only get pensions if their disease is "attributable to the Service," the decision being made "by the medical officers at the Board of Admiralty," said the Financial Secretary,[4] though he allowed, later, that it might be fair to say that the rules by which these matters were judged were too severe, and that the doctors were not given sufficient latitude. And that seems not unlikely,

[1] Journal of the Royal Naval Medical Service, January, 1927, p. 26.
[2] Arch. de Médicine Militaires, 1927, lxxxxvii., 570.
[3] Military Surgeon, July, 1925, p. 1.
[4] Hansard, March 7th, 1928, col. 1177.

for the First Lord wrote [5]: "Before a disease can be accepted as attributable to the Service it must be shown to have developed out of unusual conditions." But phosphorus necrosis of the jaw surely developed out of what were thought to be usual conditions; was it not then attributable to yellow phosphorus match-making? But that will fail to be considered by the Joint Committee sitting now and examining the question of attributability, and one hopes the, also recently announced, special Medical Consultative Board on hygienic conditions may lessen the number of cases.

When I was a junior officer we often heard, "They do these things better in France," not so often perhaps now, yet it may be well to inquire what they do there. In the *Archives de Médecine Militaires* (the French *R.A.M.C. Journal*) for 1924, lxxx., 290, is a paper on disability pensions by Médecin Major R. L. J. Boyé, who declares that before the war the French citizen discharged his military service mostly at his own risk, but that now that risk is carried for him by the public, by the Law of March 31st, 1919. Its Article 1 begins: "The Republic, grateful to those who have secured the safety of the fatherland, proclaims and determines they have a right to pension," after August 2nd, 1914. Article 3 states that rights to pension arise from injuries certified before the man returns to his home, or from diseases caused or aggravated by the toils, dangers, or accidents of service. Article 5: all diseases in a soldier or sailor, either during service or during the six months following his discharge, are presumed, unless there be proof to the contrary, to have been contracted in or aggravated by the toils, dangers, or accidents of the service. The amending law of 1923 lays down that the "presumption" above comes into force the day the recruit is passed "fit for service" (after a detailed examination as searching and documented as for life insurance). Up to that time, if invalided, he is only pensioned under the old law, his disease must be proved due to the Service. Dr. Boyé suggests that a man, getting scarlet fever after arrival, and having to be invalided with chronic nephritis, would probably be pensioned under the old law.

"The Republic, grateful to those who have secured the safety of the Fatherland . . ." is a fine gesture, too, to the men; has England had less cause for gratitude than France, will she have less in future to the men who are not conscripted, but volunteer to serve for her protection?

If the Admiralty does not support these consumptive invalids, I suppose the guardians must. So, in any case, the public has to pay. But the period of transfer, the interim of uncertain rearrangement, is very hard on a consumptive patient who has to learn the completely new hierarchy that will by and by take him over when he has become known to them. Why should his old masters, if grateful, let their responsibility for him devolve on others? Feeling themselves the expense tuberculosis entails, they might the more busily search to end it.

I am, Sir, yours faithfully,

W. E. HOME,
Fleet Surgeon.

Naval and Military Club, W., May 1st.

SUBCUTANEOUS EMPHYSEMA DURING PARTURITION.

To the Editor of THE LANCET.

SIR,—I was interested to see in your issue of April 14th (p. 757) the report by Dr. Salmond of a case of surgical emphysema during parturition. I never saw or heard of such a complication during six months' clinical clerking at the Rotunda Hospital, but I had a similar case about six years ago in Valparaiso, which I did not report. It was the first confinement of a frail woman, the first stage of labour was prolonged, the membranes having ruptured early. During the expulsive stage the head came down to the perineum, the pains being strong and prolonged with short intervals. After the second stage had lasted two hours I applied forceps as the patient was beginning to show signs of exhaustion.

On my first visit next day she was very well, but remarked: "Doctor, I am all swollen with a curious tender feeling in the skin." There was typical emphysema reaching from the nipples under the breasts upwards over the clavicles to the neck, mastoid region, over the mandible and lower half of the face, upper shoulders and neck at the back, with no pain, but some tenderness on pressure. No treatment was given. The condition lasted about a week and the puerperium was otherwise normal.

I do not think that the condition can be explained satisfactorily merely on the assumption of the rupture of one or more air-vesicles into the mediastinum or the subcutaneous tissues, because if that were so once the rupture is produced, all the air forced out during each successive effort at short intervals and under very great pressure would soon cause some kind of distress or show itself as a localised swelling at some spot before giving rise to the typical sensation of surgical emphysema.

There must be some other explanation of a complication which leaves no after-effects. I have attended this same patient in three subsequent confinements without forceps, the last one a breech presentation without recurrence of the complication.

I am, Sir, yours faithfully,

S. M. WELLS.

Queensborough-terrace, Hyde Park, W., April 23rd, 1928.

ANATOMICAL NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—The Basle Nomina Anatomica (B.N.A.), containing some 4500 names, was promulgated, chiefly by the German and Austrians in 1895. After 33 years the Anatomical Society of Great Britain and Ireland, taking exception to 56 of these terms, has, with a view to their discussion at a meeting, just issued them to its members in a list in three columns, of which the first is headed "B.N.A. term," the second "Suggested Substitute or Translation into English," and the third "Reasons." Has the B.N.A., then, as a whole been accepted in England by anatomists and is it being used in medicine and surgery and their allied sciences? has all thought been abandoned of a truly international nomenclature? or even of an English nomenclature leading on towards an international? And what about France? For each nation to retain its own nomenclature or to adopt substitutes, even if only for those terms which it dislikes, is everlasting Babel.

The present moment is critical. Instead of pursuing our own bêtes-noires and crushing them out of existence let us find principles—not such that they all must determine the nature of each structure, which is impossible, but such that one or more will give every structure a name so reasonable and so convenient as ultimately to win unanimous approval even when that involves compromise. In a crowded afternoon to discuss for a few minutes 56 terms out of 4500 is to tickle Niagara with a straw. So serious and so subtle are the pitfalls that even the list just issued proposes for one correct and convenient B.N.A. term a substitute no more convenient and anatomically inaccurate. General principles readily solve the difficulty, and provide a term as accurate as the B.N.A., more convenient than either, and comprising both.

Would it be possible, then, for the Anatomical Society to meet eminent medical and surgical practitioners, specialists and otherwise, not to discuss particular terms, but to seek means of securing principles on which to base such a nomenclature as would appeal to all English-speaking teachers, students and practitioners, and also mutatis mutandis to all teachers, students, and practitioners speaking other tongues?—I am, Sir, yours faithfully,

WM. CUTHBERT MORTON,
Hon. Demonstrator in Anatomy,
Leeds University.

May 7th, 1928.

LIVER IN PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—As the disease appears to have belied the readful title its name ceases to be descriptive, and only for this reason, we should revert to its former esignation—Addison's anæmia.

Dr. Knyvett Gordon's conception of the disease THE LANCET, May 5th)—"the persistence of nbryonic *erythropoiesis* in the liver"—cannot possibly e upheld. For some unknown reason attention has een focused almost entirely on the hæmoglobini- rous cells and their precursors; but dramatic as the anges in these cells and the appearance of the egaloblast are, equally striking features are present the other descendants of the hæmocytoblast. The normal myelocytes and eosinophils in the blood ream, the polymorphs of normal size with hyper- gmented nuclei so often encountered in films and in arrow puncture, the right-handed polynuclear unt, the frequent presence of macropolycytes of ype I., and in the terminal stages, of the mega- ryocyte type, show that the granulocyte series is so profoundly affected. Many of the cells in ldison's anæmia have no prototype in the human, ammalian, or avian embryo. And why limit the thological process to the liver when the mesen- yme descendants in other parts are abnormal?

A view that has some confirmation, both experi- entally and clinically, may be briefly mentioned. he hæmocytoblast is abnormal from birth, but rforms its functions sufficiently well for the main- nance of health until abiotrophy occurs. Chemically normal erythrocytes are then formed, and these e readily phagocyted by the cells of the reticulo- dothelial system in the spleen, liver, hæmo-lymph nds, and in the marrow itself. The alteration in e environment of the hæmocytoblast produced by is intracellular hæmolysis still further embarrasses e failing parent and mesenchyme descendants uated in places other than the marrow attempt to vert to their embryonic function. On account of the ered environment true metaplasia cannot take ce and the result is an abnormal reversion. This te continues until either the reticulo-endothelial stem becomes refractory and phagocytosis ceases, dietetic alteration restores some essential constituent the plasma. A remission occurs, followed by a apse when the environmental state of the abnormal mocytoblast again becomes unfavourable.

This view includes both the congenital and the chemical hypotheses, so interlinked as to be eparable, and however tempted we are to ascribe e disease to the one or the other, both factors, in the sent state of our knowledge, must be considered ether. The abnormal hæmocytoblast cannot be arated from its environment, nor can we say that cell itself is not solely responsible for that vironment. I am, Sir, yours faithfully,

Vigan, May 5th, 1928. W. E. COOKE.

THE MEINICKE REACTION.

To the Editor of THE LANCET.

SIR,—This micro-reaction for determining the philitic or non-syphilitic character of serum was lt with by Dr. David Prentice, in your issue of rch 10th (p. 493), who gave a full account of the ails of the method as well as evidence of its great lity. The inference to be drawn from his account that he, like Kovács, whom he quotes, would be isfied with the reaction as an exclusive routine test cept in certain instances for which the Bordet- assermann method cannot as yet be discarded. rther evidence to this effect is available from the rk of Jaubert and Gory,[1] who examined 610 samples of syphilitic serum and 1490 samples of serum from other patients in the Hôpital Broussais, using a tolu antigen prepared by the method of Mutermilch of the Pasteur Institute. The sensibility of this antigen is as great as that of the German product. It was impossible to establish a comparison between the sensibilities of the Bauer-Hecht reaction and that of Meinicke for the different forms and manifestations of syphilis. The B.H. reaction was tested, with precise determinations of the hæmolytic index, in 2100 samples. The greatest importance is attached to the technique of preparing the emulsion, which is much the same as that given by Dr. Prentice, but heat (*à chaud*) is recommended. The stability of the emulsion of tolu antigen is shown by its remaining clear for more than a year. In 91 per cent. of all cases the Meinicke reaction permitted definite classification of the serum as positive or negative. Dr. Prentice found agreement between the Meinicke and Wassermann reactions in 93·3 per cent. of cases. The authors consider the reaction to be of great value in the battle with syphilis, and it is so simple that it may be employed by everybody and everywhere. Practitioners are advised to exact its use in laboratories to which they look for diagnosis, or at least to insist on the simultaneous use of different methods.

I am, Sir, yours faithfully,

University College, Cork, May 3rd, 1928. D. T. BARRY.

HAS THE CAMPAIGN AGAINST VENEREAL DISEASE BEEN A FAILURE?

To the Editor of THE LANCET.

SIR,—All will agree with Mr. Johnston Abraham that more beds are needed for the treatment of gonorrhœal cases in women, especially those who work in an out-patient clinic. Our experience in the female V.D. department of the Royal Free Hospital confirms the opinions of Dr. Cumberbatch and Dr. Robinson, that the treatment of chronic gonorrhœa in women by cervical or urethral diathermy is, in many cases, the method of choice, but we differ from them as to the speed with which these cases can be rendered non-infectious. We find that cases which yield satisfactory results after only three to six diathermy applications include only (1) non-gonococcal cases of chronic urethritis and cervicitis, and (2) cases which, though at one time positive, have been subjected to a course of treatment other than diathermy and no longer show bacteriological signs of infection. We can quote six cases of gonococcal urethritis from our numbers, five of which showed pus and gonococci in the films after 4, 6, 7, 9, and 15 applications of diathermy respectively, while the remaining case showed pus in the urethral films after 24 applications. Several cases appeared to be free from infection at the end of six applications but, in the course of a few weeks, pus was again found in the films. These cases were nearly all either single girls or married women living apart from their husbands, where presumably there was no reinfection.

In our opinion diathermy applications are certainly the most adequate means of bringing a chronic gonococcal infection to an end, but the time taken up by a course of such tedious length makes it impracticable on a large scale in an out-patient clinic.

I am, Sir, yours faithfully,

ELIZABETH GOURLAY,
Assistant to the Medical Officer in Charge, Female V.D. Department, Royal Free Hospital.

May 8th, 1928.

To the Editor of THE LANCET.

SIR,—Dr. Tytler Burke's letter calls for a reply. He is right in inferring that I suggest the operation of vasotomy should be done in all cases of acute, chronic, anterior and posterior gonorrhœa. I have so far found no difficulty in doing so in these cases. As the rationale of this treatment is based on the attempt to disinfect the tract from beyond the limit of extension

of infection it is obvious that it should be applied in every instance. In a case of acute gonococcal anterior urethritis my practice is to inject one vas at once, and if the discharge has not disappeared at the end of a week to inject the other vas. I can strongly recommend this treatment to Dr. Burke and will be very interested to hear of his experience which will be valuable. With regard to detention in bed my remark did not apply to cases where constitutional symptoms necessitate rest in bed. But in the absence of these I find no objection to allowing the patient up after 24 hours with a collodion dressing.

I am, Sir, yours faithfully,

Harley-street, W., May 4th, 1928. J. F. PEART.

To the Editor of THE LANCET.

SIR,—Dr. Peart's claim that "injection of the vas" has in his hands been "absolutely reliable in dealing with every stage" of gonorrhœa astonished me, in view of my impression that such treatment had been largely given up, even for chronic vesiculitis; as wide investigation during the last five years had shown that it was neither free from risk of damage to the vas nor was very reliable as a cure, although of undoubted value in some cases. It is difficult to understand the raison d'être of treatment of any other gonococcal condition than vesiculitis by way of the vas, and, personally, I should consider vasotomy and injection of vesicles as unjustifiable and contra-indicated in the absence of symptoms suggesting gonococcal infection of the vesicle.

It appears to be unreasonable to claim that urethral folliculitis, probably the commonest complication of gonococcal urethritis, can be influenced in any way by injection of the vas with any antiseptic. It would be interesting to know the number and nature of the cases on which Dr. Peart founds his dogmatic statement in favour of treatment per vasa rather than per urethram in "every stage of the disease." I venture to suggest that intravenous injection of sulfarsenol as recommended by Dr. Carminow Doble, and diathermy of the prostate per rectum as introduced by Dr. Cumberbatch, are more likely to be of value in the treatment of epididymitis and prostatitis, in additional to the usual routine treatments of these conditions, than any treatment per vasa.

I am, Sir, yours faithfully,

H. WANSEY BAYLY.

Harley-street, W., May 7th, 1928.

MULTIPLE DENTAL EXTRACTIONS.

To the Editor of THE LANCET.

SIR,—It is not easy to decide between the "all at once" and "a few at a time" arguments of Dr. Hilliard and Mr. Johnson. In nine cases out of ten the patient's mouth will probably make a good recovery whichever method is adopted. In the tenth case, where there has been systemic infection from the sockets and the resistance is dangerously low, it is not obvious that multiple extractions will have worse results than the extraction of three or four teeth, three or four times repeated. On the whole, my impression is that the latter procedure has been less well borne. But has not the time come to abandon these haphazard and speculative methods? We are now able to have the blood tested, and if the non-specific bactericidal power is found to be dangerously low, it is possible to increase it substantially by ultra-violet body-baths or by really effective irradiation, producing erythema, in the mouth itself—the former method being, in my judgment, preferable from every point of view. This may, or may not, involve the postponement of the operation for as much as a week, but it is certainly calculated to promote rapid and painless healing and to prevent residual sepsis—a frequent and formidable sequel.

I am, Sir, yours faithfully,

London, W., May 8th, 1928. F. TALBOT.

DOCTORS AND THE NURSING HOMES REGISTRATION ACT, 1927.

To the Editor of THE LANCET.

SIR,—It has taken a quarter of a century to effec the legal registration of nursing homes, but those wh first advocated this legislation—yourself among other —never anticipated the inclusion of doctors' house and still less the exclusion of Christian Science homes It may be of interest to recall that the first publi discussion on the subject took place at the congres of the Royal Sanitary Institute at Bradford in 1903 and was quickly followed by a leading article an correspondence in your columns.

I am, Sir, yours faithfully,

E. M. HOMERSHAM,

Devonshire House, King Henry's-road, N.W., May 5th, 1928. Assoc. R.S.I.

MEDICAL AUTOGRAPHS.

To the Editor of THE LANCET.

SIR,—I am endeavouring to compile a list o medical societies or institutions that possess collection of medical autographs, my purpose bein to encourage this method of perpetuating the memor of those pioneers of medicine who have for the mos part passed beyond the veil, but whose names live a the benefactors of mankind. The extensive collectio that are possessed by the Royal College of Physician of London, the Royal College of Surgeons of Englan the Royal Society of Medicine, and that more recentl acquired by the British Medical Association a familiar to me, but there must be many othe professional societies both at home and abroad tha have recognised the historical interest of such litera memorials, especially when associated with an albu of portraits. I shall be grateful if such societies wi furnish me with some particulars of any collectio they possess.—I am, Sir, yours faithfully,

JAMIESON B. HURRY.

"Hinton Firs," 15, Gervis-road, Bournemouth.

VISIT OF DR. SCHWEITZER TO ENGLAND.—D Albert Schweitzer, who is on furlough from his hospit work at Lambarene in Central Africa, will be giving a seri of organ recitals and lectures during the month he is spendi in England. On Wednesday, May 16th, at 7.30, he w give a lantern lecture on his work, at Friends Hous Euston-road, London.

DONATIONS AND BEQUESTS.—The late Mr. Willia Fletcher Moore Patten, of Hove, left, in addition to oth bequests, £2000 to the Sussex County Hospital and £10 to the Royal Alexandra Hospital for Children, as well £200 each to the Victoria Jubilee Annuity Fund and t Molyneux Asylum for the Female Blind, Dublin. On t death of his aunt £2000 will go to the Alton Childre Hospital and College and £1000 to Reedham Orphanage. By the will of Miss Emma Tedbury, of Exeter, the followi bequests have been made: £300 to the Cottage Hospit Budleigh Salterton; £100 each to the West of England E Infirmary, the West of England Blind Institution, t Royal West of England Deaf and Dumb Institution; a the residue of the property to the Royal Devon and Exet Hospital.—After the fulfilment of certain bequests M William Thomas Higginbottom, of Blackburn Pa Didsbury, left £1000 each to Manchester Royal Infirma Dr. Barnardo's Homes, Ancoats Hospital, and Ardwick a Ancoats Dispensary, and £500 to the Christie (Cance Hospital, Manchester.—Among other large bequests the la Alderman F. C. Clayton, of Edgbaston, left £3000 to Quee Hospital, Birmingham, with the request that this sum shou be used for a Queen's Hospital Convalescent Fund, for t benefit of in-patients of that hospital by the purchase tickets for their admission to the Sanatorium at Blackwe or otherwise in procuring for them change of air and res £1000 to the Queen's Hospital, Birmingham, for gene purposes; and some £353 per annum from ground rents the University of Birmingham. Under the same will t University of Leeds will receive £2000 in stocks to found Richard Reynolds scholarship in chemistry or pharmacy.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

NATIONAL HEALTH INSURANCE BILL.

Payment of Insured Persons While in Hospital.

WHEN the Committee resumed its sittings on April 26th, Sir KINGSLEY WOOD (Parliamentary Secretary to the nistry of Health) referred to the promise given by Mr. namberlain at the previous sitting to reconsider his attitude regard to the payment of sickness and disablement nefit while insured persons were in a poor-law institution, spital, or other institution. His right hon. friend cognised, he said, that there might be cases where a lump m should be given, and if Mr. Broad would withdraw his nendment he (Sir Kingsley Wood) would be prepared to ove an amendment providing that the matter should be t to the discretion of the society or committee.

Dr. VERNON DAVIES: Does this mean up to the maximum £50?

Sir KINGSLEY WOOD: Yes.

Mr. BROAD'S amendment was withdrawn and Sir KINGSLEY OOD'S proposed amendment was agreed to.

Clause 3: Administration of Medical Benefit.

On Clause 3 (which amends Section 24 of the principal t as to the administration of medical benefit),

Mr. JOHN said he wished to oppose the clause on the ound that it proposed to refuse recognition or approval medical institutions that have been approved for the t 13 or 15 years, and also prevented similar institutions m being recognised or approved in future. He was a loss to understand why this clause had been inserted, cause the medical schemes or institutions which were existence met the desire for a greater scope in medical eatment or benefit than could be given by the individual nel practitioner. The Act itself only gave the insured rson a guarantee of one doctor, who was not called upon have more skill than could be reasonably expected. The edical institutions to which he referred coördinated medical eatment and benefit in such a way that the members re entitled to the services of a number of doctors in spect of both medical and surgical treatment. They re also entitled to electric treatment, massage, light eatment, and laboratory advice. If it was intended to use recognition to these institutions, a large number of em would be placed in an awkward position.

Sir KINGSLEY WOOD said that although he did not wish condemn what had been done under the guise of making dividual arrangements, unfortunately a number of insti-tions had purported to make arrangements to escape the dinary normal arrangements of medical benefit. When e Act was passed it was never intended that a number of ople should be able to band themselves together, and by me sort of device, put themselves in exactly the same sition as those existing institutions which were covered Section 24 of the principal Act. The result was that the partment had found itself with little or no control over ch institutions. It had been the sole aim of the Ministry Health to see that the Act was properly administered, d particularly that the standard of medical treatment as as high as they could make it. It was very unfair, d not right, that a number of these so-called institutions ould be in the position of being under no obligation to nder any returns to the Department and over which ey had no effective control, to see that the standard of edical treatment was sufficient. When he told the mmittee that this sort of society made a profit out of a atter in which there ought not to be any profit, and that e payment to the doctors was not of a nature which sured the best medical attention, he thought they would ree that the Government were right to intervene as they d done under this clause. They said that if existing stitutions wished to put themselves within the same nditions as the old existing societies under the principal ct, and have the same objects and purposes as the old cieties which had to obey rules and regulations, then ey must apply to the Ministry of Health. If they did so eir claims would be examined sympathetically, but with e sole object of ensuring an adequate standard of treatment r their members. He also wished to make it quite clear at if such societies were approved they would have to pply proper returns to the Department and generally nduct their institutions in the same manner as the original stitutions had to do.

Dr. DAVIES said that if Sir Kingsley Wood meant that it as quite possible that in future the Ministry would sanction her schemes on similar lines to existing schemes, he would very much opposed to such a course. "Institutions" as another name for colliery clubs. On the second reading of the Bill he spoke in favour of those clubs, and said that they had done extremely good work, but he sincerely hoped that no new ones would be allowed.

Sir KINGSLEY WOOD: No new ones?

Dr. DAVIES said that the right hon. gentleman's speech was not very definite on the point. The success of all these institutions depended on the standards and qualifications of the medical men. He said, on second reading, that he was quite convinced that the medical men associated with these schemes were competent in every shape and form, and that they had done, and were doing, extremely good work, but they had to bear in mind that for some years now the British Medical Association had set their face very definitely against this type of institution or practice. Every week they put in the *British Medical Journal* a warning notice asking anybody applying for such a job to consult them first. When the present competent medical men retired, those who took their places would do so contrary to the advice of the British Medical Association; the highest type of doctor would not apply for these appointments. The majority of medical men liked to keep in touch with, and sympathy with, their fellows, and if they found that a big proportion of the profession said: "We would rather you did not take these appointments; perhaps it is not unprofessional, but it is inadvisable to do so," the best type of medical man would not accept such appointments, and ultimately they would be landed with a type of medical man, who though fully qualified was yet perhaps not the highest type of man in the profession, and ultimately the nstitutions would suffer.

Sir KINGSLEY WOOD said he would not like the medical members of the Committee to be disturbed, and he would give an assurance that the Department had no intention of dealing with any but those systems and societies which were already in existence. They did not propose in any way to encourage the practice.

Dr. WATTS said that he did not wish to encourage these institutions but if the clause was allowed to remain there was a danger. With the growing discontent in the country generally with the nature of the treatment people got under National Health Insurance, a large number of persons were anxious to band themselves together in order to make arrangements with private doctors under a system by which the insurance committees would hand over to them the capitation fee, and the patients would be willing, so he was informed, to pay a supplementary fee in order to make sure that they got decent attendance as insured persons. He held no brief for the institutions or clubs; he believed the medical attendance they gave to be equally as bad as—if it were possible to be as bad as—the medical attendance under National Health Insurance. (Laughter.) Hon. Members might laugh, but he was speaking from some knowledge of the matter. It was not the fault of the doctors. Under the National Health Insurance scheme a doctor's time was taken up in a large measure by red-tape regulations and by keeping silly records which were of no use to anybody, and which, when they arrived at the Ministry of Health, were, he was given to understand, destroyed, no use being made of them. If certain groups of the insured population banded together and made a private arrangement with medical men they would be prevented from doing so by this clause, and he therefore supported the proposal to delete it.

Mr. JOHN withdrew his opposition to the clause, which was agreed to.

Clause 4: Subscriptions to Charitable Institutions.

On Clause 4 (amendment of Section 26 of the principal Act as to subscriptions to charitable institutions). The clause provides that a society "in the case of which no disposable surplus was disclosed on the last preceding valuation, or an insurance committee, may from time to time, with the consent of the Minister, make subscriptions or donations of an eleemosynary character to hospitals and similar institutions."

Mr. BRIANT moved to leave out the words "of an eleemosynary character." His object, he said, was to remove any difficulties in the way of extending these subscriptions to any likely societies that might not exist at present, but might exist in the future.

Sir KINGSLEY WOOD said that this was perhaps a more important amendment than the hon. gentleman might realise. The particular words to which he had taken exception were intended to emphasise the nature of the subscription to be made by the societies to charitable institutions, and the intention was to limit the contribution which the society should make to general charitable gifts of an unconditional character, having regard to the excellence of the institution and the good that it was doing. The clause endeavoured to put an end to a system by which advantage was taken to enter into contracts with institutions and, in return, receive certain benefits for the society's members. They desired to see that if the societies made

charitable gifts in the future they should be genuine and not the kind of thing to which he had referred.

Dr. DRUMMOND SHIELS said that he would like the Parliamentary Secretary to the Ministry of Health to explain the term "contracts" used in his speech. The speeches which the Committee had heard had shown the obviously unsatisfactory character of the present medical attention given under the National Insurance Act, and they were warned against societies competing against each other to provide benefits under this scheme. He was interested in this section in connexion with the important matter of specialist benefit. He understood that societies in the past had tried to make arrangements with voluntary hospitals that, in return for a donation, a certain number of beds would be set aside. He knew that in many cases arrangements had been refused, as the managers of voluntary hospitals had not felt that they were entitled to make such allocations. He would like to know if an arrangement with a voluntary hospital for a certain number of beds to be set aside for a particular approved society would be allowable under this clause?

Sir KINGSLEY WOOD said he thought that the hon. Member would have an opportunity of raising this matter on another part of the Bill.

Lieut.-Colonel FREMANTLE asked whether such invaluable agencies as district nursing associations, the Queen Victoria Jubilee Nurses, and midwives societies, had been definitely and intentionally omitted, or were they included under the words "similar charitable institutions"?

The amendment was withdrawn.

Mr. HARVEY moved to leave out the words "and similar" and to insert thereof the words "dispensaries and other."

Sir KINGSLEY WOOD said he could assure his hon. friend that they did not want to rule out any charitable gifts of such a character as those to such an institution as the District Nursing Association. On the other hand, he must call the attention of the Committee to the fact that for the first time the schedule made provision for the payment of the whole, or any part, of the cost of the provision of nurses for members.

The amendment was agreed to.

The National Health Insurance Bill was further considered by Standing Committee of the House of Commons, and a detailed report will be given in a coming issue of THE LANCET.

HEALTH INSURANCE (PROVISIONAL REGULATIONS).

On Thursday, May 3rd, on the motion for the adjournment,

Mr. A. V. ALEXANDER said he desired to bring to the notice of the Government a very strong protest, first of all with regard to the increasing practice of making new breaches of contract and creating new crimes and penalties by means of regulation instead of by Act of Parliament. The necessity for some regulations under the National Health Insurance Act was apparent, but in the regulations to which he desired to draw attention, a very vital principle was involved which ought not to have been dealt with by regulation, but ought to have been the subject of amending legislation. The regulation of which he complained was found in the Medical Benefit Regulations (No. 2), 1928, which was laid on the Table of the House on April 17th. In those regulations they found the extraordinary clause:—

> Clause 4 of Part I. of the Third Schedule to the principal Regulations shall be read and have effect as if the following paragraph were added thereto: "A chemist shall not give, promise or offer to any person any gift or reward (whether by way of a share or dividend on the profits of the business, or by way of discount, or rebate, or otherwise) as an inducement to, or in consideration of, his presenting an order for drugs or appliances on a prescription form provided by the Committee."

Effect of the Clause on the Coöperative Movement.

He wanted members of all parties who were interested in the coöperative movement to observe that the clause prevented, in future, any chemist's department and a coöperative society from continuing its practice in so far as its business was conducted under the terms of the National Health Insurance Act. Any member of a coöperative society who was also a member of an approved society, who took a health prescription to be made up in a coöperative store instead of an ordinary chemist's shop, would not be allowed to be given a note to the effect that he had taken goods from the store at the rate of 5*d.*, which was the flat rate allowed to the chemist for his services. In 1925 the Parliamentary Committee of the coöperative movement had overtures made to it by the Retail Pharmacists' Union, desiring that coöperators should undertake that, in future, they would not allow the value of the prescription made up for their members under the National Health Insurance Act to count as part of their business for the final distribution of the surpluses of the coöperative societies. The Coöperative Committee said that they could not consider such a proposal, because it would cut at the root of the basic principle on which the coöperative movement did business. He had obtained an assurance from one of the principal officials of the Ministry of Health that there was nothing against the practice of allowing a member of an approved society, who was a member of a coöperative society, to share in the rightful benefits of his mutual association. Since then they had never received a word of communication from the Ministry of Health. On April 21st, however, a circular was issued to the local insurance committees, which was obviously a circular issued from headquarters. The regulations did away entirely with the present perfectly genuine trade practice of the coöperative societies in this country. The reason for the Retail Pharmacists' Union bringing pressure to bear on the Government in this matter was simply to get the Government to take sides against a body which they regarded as a trade competitor. He imagined that the only real ground of defence which the Minister of Health could possibly put forward for this action was that it had been stated that considerations were being given for prescriptions to be taken to certain chemists, and that that might lead to corruption and malingering. How many prescriptions would have to be used up by a person before he could get any substantial monetary advantage to the extent of leading to malingering? If there existed a real danger of considerations being offered to aid malingering, what were the doctors doing? Surely it was the duty of panel doctors to see that they gave prescriptions only where there were genuine cases to be treated.

Increased Cost of Drugs and Appliances.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said the regulation to which Mr. Alexander had referred was not directed against any particular body, association, or individuals, but was in the true interests of the proper administration of the National Health Insurance funds. It was well known that the position of the drug fund in connexion with national insurance had given serious anxiety to the Government and the approved societies. There were some 11,000,000 people in England and Wales who came under the ordinary drug arrangements with chemists. The average cost of drugs and appliances so far as the National Health Insurance Act was concerned had very steadily and very seriously increased. For instance, in 1916 the total cost of drugs and appliances supplied by chemists was £634,651. In 1926 that figure had risen to a sum of £1,729,078, and the Ministry of Health had been driven to the conclusion, which he thought was shared by those people who had been concerned with the administration of National Health Insurance, that whilst a certain increase was no doubt due to increased sickness, there was considerable evidence of extravagant prescribing. The difficult situation was accentuated because, under the National Health Insurance Act there was only a certain sum permitted for the cost of drugs. Directly that sum was exceeded a serious question arose as to where the increase in cost was to come from. The question that confronted his Department was whether there should be a revision of the drug tariff, or whether the fees ought to be reduced. If either of these matters were to be taken in hand it would undoubtedly be very serious, especially so far as the smaller chemist's business was concerned. Therefore his Department had several consultations with the Retail Pharmacists' Union, which represented some 8000 chemists throughout the country. They pointed out to the union that this was a case which obviously had to be met, and asked whether the union was prepared to take the matter in hand and set their own house in order? The representatives of the union gave an undertaking to his Department that they would be responsible for the proper administration of the fund, and see that it was conducted within its proper financial limits, and that the service was adequate. But, as was perfectly natural, the union said that if they were going to take this unlimited liability, proper conditions must be laid down as to the administration of this drug traffic. To show the House that there was no attack upon the coöperative societies he would cite certain instances to indicate what occurred in relation to this important benefit. A leaflet had been distributed broadcast in a particular area of London to the following effect:—

> "Insured persons will receive a free gift, value 6*d.*, for two weeks only, Sept. 19th to Oct. 3rd, 1927. Every person bringing a panel prescription to be dispensed at the above address will receive, free of charge, certain items value for 6*d.*"

Then there was the further statement:—

> "No matter where you live or who your doctor is, you are quite free to bring your prescription to Mr. ——. He is the most reliable chemist in the district."

That was, the gentleman who was offering 6*d.* He said:—

> "He is really interested in your particular case, and will give free advice to patients if required. Please bring your prescriptions as early in the day as possible. Note only address. No branches."

le (Sir Kingsley Wood) had another leaflet issued by a hemist who offered in the same way another inducement o insured persons to go to him with their prescriptions, nd in another case a draw was to take place among insured ersons, and it was stated that the insured person who took is prescription to the particular chemist and drew the inning number, would receive a solid-gold wristlet watch. very member of the House would see that that was a most ndesirable practice, and they had therefore laid down in his regulation that these inducements and gifts were not o be given. Once they directed a regulation of that kind gainst this particular practice, they obviously could not, n fairness to the other chemists who administered the Act, ermit inducements to be given by coöperative societies n the same connexion.

The motion for the adjournment was carried by 200 votes o 97.

HOUSE OF COMMONS.

WEDNESDAY, MAY 2ND.

Preservatives in Butter and Cream.

Mr. THOMAS KENNEDY asked the Secretary of State for cotland if he had received any representations from traders n Scotland regarding the effect of the regulations prohibiting he use of preservatives in butter and cream; and whether, n view of the special difficulties in Scotland involving serious ss to retail traders through the regulations, he would onsider the desirability of modifying the restriction on the se of preservatives during the summer months.—Sir J. ILMOUR replied: I have received the representations eferred to by the hon. Member. I have also received epresentations supporting the prohibition of boric acid n cream. As advised, I see no reason to modify the estriction on the use of preservative for these articles.

Regional Medical Officers' Fees.

Mr. BROMFIELD asked the Minister of Health whether he as prepared to allow regional medical officers' fees paid y approved societies to be charged against the benefit nd account instead of against the administration account, n view of the fact that a large number of approved societies ere on the border-line in respect to administration, which ct had a tendency to prevent societies using the regional edical officers as often as they would do if the cost was orne by the benefit funds instead of, as now, by the dministration account.—Mr. CHAMBERLAIN replied: No, ir. The fees in question are part of the administrative xpenditure of Approved Societies, and must, under the ct, be charged to the administration account. An increase as been made, as from the present year, in the amount per ember which societies may appropriate for purposes of dministration, and I have no reason to think that the harges for references to the regional medical Officers, hich amount on the average to under a halfpenny per ember per year, cannot be met in the proper way out of he administration account.

Accidents in the Woollen and Worsted Industries.

Mr. JOHNSTON asked the Home Secretary the number of ccidents caused by lifting heavy weights in the woollen and orsted industries prior to the order fixing maximum eights compared with the number of such accidents since he order became effective.—Sir WILLIAM JOYNSON-HICKS eplied: I regret that the figures necessary for any such omparison cannot be given. At the time these regulations ere made, no evidence was available as to the total number f cases of injury from lifting of heavy weights. What appened was that one of the employers' associations ubmitted to the Factory Department evidence of injuries o workers employed in their section of the industries, and n this evidence the Factory Department invited the ational Wool (and Allied) Textile Industrial Council to ake the matter up. The Council thereupon appointed a pecial committee, on which both employers and workers ere represented, to investigate the question. As a result f this inquiry unanimous agreement was reached and the egulations were made, at the request of the Council, to give ffect to this agreement.

THURSDAY, MAY 3RD.

School Medical Services.

Dr. VERNON DAVIES asked the President of the Board f Education the cost of the school medical services classified nder medical officers, nurses, school clinics, and treatment y dentists and oculists, for the last three years, respectively?—The Duchess of ATHOLL (Parliamentary Secretary o the Board of Education) replied: I am afraid that the eturns made by local authorities do not enable me to nalyse the expenditure under the heads named in the uestion, but the total cost of the school medical services for the last three years for which returns are available are as follows:—

	Gross expenditure.	Receipts.	Net cost.
	£	£	£
1924–25	.. 1,307,228	 53,899	 1,253,329
1925–26	.. 1,441,415	 60,970	 1,380,445
1926–27	.. 1,516,995	 66,010	 1,450,985

Substitutes for Cream.

Viscount SANDON asked the Minister of Health if he had any information as the the use of substitutes for cream by bakers and confectioners involving the breach of the Milk and Dairies Act; and what steps were being taken to circumvent this.—Mr. CHAMBERLAIN replied: It is a well-known fact that substitutes for cream are commonly used by bakers and confectioners, but so long as these substitutes are not injurious to health and the articles in which they are used are not incorrectly described. There is no offence in regard to which statutory proceedings could be taken. It is not a matter to which the Milk and Dairies Acts apply.

Miners' Phthisis.

Mr. DAVID GRENFELL asked the Home Secretary whether he had definitely arranged for the extension of the schedule of industrial diseases so as to include men who contracted miners' phthisis while following the occupation of rock-boring in coal mines by the use of compressed-air machines; and how many cases of disability from this cause had been notified to his department in the last four years.—Sir WILLIAM JOYNSON-HICKS replied: The matter is one which will have to be dealt with by a scheme under Section 47 of the Workmen's Compensation Act, 1925, and I have asked the Departmental Committee on Workmen's Compensation for Silicosis to advise as to the terms of a scheme. I have offered for this purpose to appoint to the Committee two representatives of the industry on each side, but have not yet received the reply of the Miners' Federation. The disease is not notifiable and no statistics are available, but its incidence, to a limited extent, in the coal-mining industry has been established.

Vaccination Committee's Report.

Lieut.-Colonel FREMANTLE asked the Minister of Health when the Report of the Departmental Committee on Vaccination would be published.—Mr. CHAMBERLAIN replied: This report is now being printed and will be published at an early date.

Treatment of Venereal Disease.

Miss LAWRENCE asked the Minister of Health the amount of grant given towards the treatment of venereal disease in the years 1921 and 1927, and the amount which local authorities had been informed was the maximum they would receive for the year 1927–28; the number of treatment centres for venereal disease in England in 1921 and at the present time; and the number of health authorities where no such centres were provided.—Mr. CHAMBERLAIN replied: The grants paid to local authorities for this purpose amounted to £421,687 and £272,921 during the financial years 1921–22 and 1927–28, respectively. The maximum grant payable to these authorities in respect of the financial year 1927–28 is £286,763. There are at the present time 177 treatment centres in England, compared with 184 in 1921, the reduction being due mainly to the policy adopted in some large towns of concentrating the work of two or more centres in one centre, at which extended facilities for treatment have been provided. Facilities for the treatment of venereal disease have been provided by all the local authorities responsible for this work, but in a few cases the treatment centres are outside the administrative areas of the authorities.

MONDAY, MAY 7TH.

League of Nations and World Output of Morphine.

Mr. SCRYMGEOUR asked the Secretary of State for Foreign Affairs whether he was aware that the world output of morphine had increased between 1921 and 1926 from 30 to 60 tons; and whether, in view of the statement of the Italian representative to the League of Nations that the British Government had concealed the real figures of British drug exports, he had any official information to explain the difference between the amount of drugs imported into America and the amount admitted by British exporters.—Mr. G. LOCKER-LAMPSON (Under-Secretary for Foreign Affairs) replied: The answer to the first part of the question is in the negative. A statistical summary recently issued by the League gives the production for 1926 as 40,245 kilos, and the production for 1921 as 29,657 kilos (about 40 and 30 tons respectively), but complete statistics are not available. Both the figures in question are incomplete, and the figure for 1921 more so than that for 1926. Any comparison, therefore, between them would be unsafe.

Further, the 1926 figure includes large quantities of morphine which were produced solely for transformation into non-dangerous products, such as codein. The actual quantities of morphine manufactured for sale as such were far smaller. So far as Great Britain is concerned, the manufacture of morphine has shown a steady decrease during the last five years. I am not aware that the Italian representative on the Advisory Committee charged His Majesty's Government with concealing their drug exports. He called attention to the fact that the amount of raw opium returned by Great Britain as exported to the United States was less than the amount of raw opium returned by the Government of the United States as imported from Great Britain. This discrepancy is being examined by the two Governments, but is probably due, in part, to the fact that the returns of the two Governments relate to different periods, the British returns being for the calendar year, the United States returns for the fiscal year, from July to July, and in part to the fact that opium sold from Great Britain may not be actually exported from Great Britain, but may be conveyed direct from a foreign port to the United States. The British figures are official figures compiled from the export licences issued by the Home Office, and there is no reason to question their accuracy.

Classification of Milk.

Mr. ROBERT YOUNG asked the Minister of Agriculture the total amount of milk for commercial purposes produced during the past two years; how much of it was pasteurised milk, Grade A milk, and Grade A tuberculin-tested milk; and how much described as clean milk, purified milk, &c., was produced for consumption.—Mr. GUINNESS replied: The total amount of milk produced in England and Wales during the past two years, exclusive of milk fed to calves and pigs, but inclusive of milk manufactured into various products, both on and off farms, as well as milk consumed in liquid form, has been estimated as follows: June to May (per million gallons): 1925–26, 1135; 1926–27, 1150. As regards the proportions of these quantities which may be classified as officially designated milks, it is estimated that "Certified," "Grade A (T.T.)," and "Grade A" milks constitute approximately 1 per cent. of the milk consumed as liquid milk. No reliable estimate for "pasteurised" milk is available. The terms "clean" and "purified" are not recognised as official designations; they are entirely relative terms, and as they signify no definite or absolute standard, the quantities of milk sold under them are unknown.

Death Certificates and Reports to the Coroner.

Sir CHARLES OMAN asked the Minister of Health whether, as it was part of the duty of a registrar of deaths to decide whether to give a burial certificate or whether to send a case to the coroner, he would provide that officers of the boards of guardians should not be appointed registrars of deaths for the future, and vice versa.—Mr. CHAMBERLAIN replied: A registrar of births and deaths is required by regulations to report to the coroner every death which, on the information before him in the medical certificate or otherwise, was due to any one of certain prescribed causes or occurred in certain prescribed circumstances, and, pending consideration by the coroner, to defer registration and the issue of an authority for burial. He has thus no discretion to decide whether to report such cases or not. I am aware of no reason for apprehension that registrars of births and deaths do not discharge faithfully the duties of their office in those cases where they also hold poor-law office.

BRADFORD ROYAL INFIRMARY.—The Duke and Duchess of York have laid the memorial stones of the new infirmary at Daisy Hill. This great hospital is estimated to cost at least £500,000, of which £380,000 has already been given or promised.

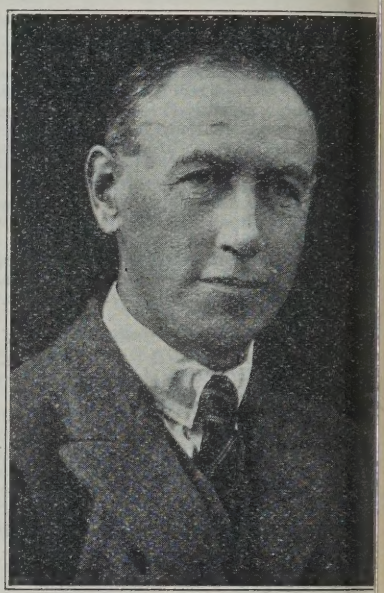
ROCKEFELLER MEDICAL FELLOWSHIPS. — The Medical Research Council will shortly award these Fellowships for the academic year 1928–29. Applications should be lodged with the Council not later than June 1st, 1928. The Fellowships are provided from a fund with which the Medical Research Council have been entrusted by the Rockefeller Foundation. Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a University or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A Fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C.2.

Obituary.

THOMAS VILLIERS CROSBY, M.D. LOND.

Dr. T. V. Crosby, of Leicester, died on April 26th after two and a half years' illness, which began just after he had retired from active practice. His death at the age of 57 will be deeply regretted by those who worked with him.

The second son of the late Mr. James Crosby, of Burlescombe, in Devon, he was educated at Blundell's School, Tiverton, and at University College, London, from which he graduated in medicine in 1894. As a student at University College Hospital and afterwards as resident, he came into contact with several men who were to be fellow practitioners and life-long friends in Leicester, where he settled on leaving London. He was appointed assistant physician to the Royal Infirmary in 1902, and his practice soon became a large one, so that assistance was eventually required. He was joined in partnership by Dr. Ernest Parker in 1916 and later by Dr. A. V. Pegge, Dr. Ernest Garratt, and Dr. Harold Ingham, all of whom, like himself, had served for a time as medical resident officers at the infirmary.



DR. T. V. CROSBY.

Photograph by F. Sproston.

Apart from his duties as a general physician, Dr. Crosby was a skilful anæsthetist. A colleague at the infirmary writes of him that he was "a conscientious worker, always ready to give a helping hand to others; always perfectly willing to assist in anything which might help in the smooth running of the medical work. His kindly disposition endeared him to patients and colleagues alike. He had many friends, enjoyed being in company, and was fond of sport, but in recent years his work monopolised his whole time and he found little chance of recreation. Country bred, he lived an active life in a large city, but his tastes were simple, he cared nothing for show, and his sympathies were broad. Such characteristics form the most laudable of our profession. The memory of T. V. Crosby will be cherished alike by patients and colleagues as one of unusual kindness."

For some years Dr. Crosby served the city as a guardian of the poor, but during the war he had to relinquish this responsibility in favour of service with the Fifth Northern General Hospital, a Territorial unit to which he was appointed, with a major's commission, in 1908. In his earlier years he was a fair shot, a good horseman, and a Rugby forward, but his leisure pursuits were reduced to a minimum long before his retirement at the end of 1926. The illness which followed was borne with the imperturbability that had characterised his professional life.

Dr. Crosby married in 1898 the second daughter of Mr. G. J. B. Woolley, J.P. She survives him with two sons, one of whom is Dr. G. J. V. Crosby, of Bushby, Leicester.

Medical News.

UNIVERSITY OF OXFORD.—At a Congregation held May 3rd the following degrees were conferred:—

D.M.—L. N. Jackson.
B.M.—C. W. Flemming.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held on May 3rd the following degrees were conferred:—

M.B., B.Chir.—P. E. Pym, G. D. Thomson.
M.B.—C. E. Kellett.
B.Chir.—G. C. Milner.

UNIVERSITY OF SHEFFIELD.—At the undermentioned examinations held recently in the Faculty of Medicine the following candidates were successful:—

Final M.B., Ch.B. (Part I.).—John D. Gray and Bessie Hatherley.

Third M.B., Ch.B.—William H. Carlisle, Abraham Cohen, Frank Ellis (with distinction in Pathology), Ralph B. Gould, Iris M. Moody, Sankar K. Panniker, Thomas H. Pullar (with distinction in Anatomy, Pathology, and Pharmacology), Isaac Slesnick, and John H. Wilbourn.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Final Examination of the Conjoint Board held from March 26th to April 20th the following candidates were approved in the subjects indicated:—

Medicine.—V. E. N. Allen, Bristol; M. A. E. Anous, Cairo and Middlesex; Lucy E. Arthur, Royal Free; H. F. Bateman, Cambridge and St. Bart.'s; W. A. Bellamy, St. Bart.'s; T. H. Berrill, Bristol; C. V. Bloom and K. C. Blyth, London; N. J. Boulton, Guy's; Beatrice A. Butterworth, Royal Free; L. A. Canaan, London; Mavis H. D. Carr, Cambridge and Royal Free; B. R. Caygill, Leeds; Nellie Clifton, Royal Free; L. I. Cohen, London; Elizabeth Cooper, Royal Free; J. H. Crawford, St. Mary's; Evelyn M. Davies, King's Coll.; W. F. de Villiers, Cape and London; Marjorie M. Dobson, Royal Free; R. M. Dowdeswell, Cambridge and St. Thomas's; Geraldine W. Everett, Royal Free; P. H. Fox, Cambridge and St. Bart.'s; Agnes B. Francklyn, St. Mary's; Leslie Godlove, Leeds; Valentina P. Guercken, Westminster; C. K. Haskard, Adelaide and London; W. E. Herbert, Guy's; Violet L. de A. Hickson, Westminster; D. R. House, Bristol; K. Jilani, Liverpool; C. H. Johnson, Guy's; Esther M. Killick, Leeds; K. E. Lane, Guy's; Jane S. McDowell, Charing Cross; K. L. Malhautra, Univ. College; A. Milner, Leeds; Edith G. Niven, Univ. College; Dorothy M. M. Rees, Charing Cross; R. D. Robinson, St. Bart.'s; W. P. Roe, Guy's; Pattie E. Rose, St. Mary's; Margaret C. Rosser, Birmingham; Alice I. Roughton, Cambridge; Eluned Saunders, Westminster; Christine F. T. Saville, Univ. College; Elizabeth S. Smith and G. A. Stevenson, Birmingham; Frances J. Vinter, Royal Free; A. T. D. Whitfield, Birmingham; and G. W. Willcox, Cambridge and St. Thomas's.

Surgery.—G. M. Ali, Royal Free; Constance E. Allen, Charing Cross; G. Allen, London; Sofia Antonovitch Royal Free; T. C. Baker, St. Mary's; W. A. G. Bell, Cambridge and St. Thomas's; G. Bellman, St. George's; H. Bernstein, Univ. College; F. A. Blackwood, St. Thomas's; J. V. Broad, St. George's; M. K. Bryce, London; Beatrice A. Butterworth, Royal Free; L. A. Canaan, London; H. A. Clarke, Guy's; A. M. Clarkson, Univ. College; W. A. Clements, Sheffield; Dorothy M. Conyers, Royal Free; S. J. Cope, St. Thomas's; T. M. Corcoran, Univ. College.; E. Courtin, St. Thomas's; A. M. Cunningham, Univ. College; T. Dagger, Liverpool; A. Danin, Guy's; H. W. Daukes, St. Thomas's; F. T. Doleman, St. Mary's; E. C. Duffett, Guy's; E. L. Edmondson, Cambridge and London; H. F. Ellis, Liverpool; J. W. Ellis and M. M. El Mishad, Guy's; G. W. Etches, Leeds; I. Friedman, Guy's; L. Godlove, Leeds; F. W. H. Grenier and J. P. Gubbins, London; H. S. Hamlin, St. Thomas's; W. F. L. Hannay, Guy's; H. Harris, Manchester; R. T. Hicks, Univ. College; B. Hoffenberg, Liverpool; J. M. Hulett, Guy's; K. T. Hunter, Toronto; J. Ives, St. Mary's; M. Jafar, Punjab; L. A. Joelson, London; S. E. Knowles, Guy's; M. L. Kreitmayer, St. Bart.'s; A. J. C. Latchmore, Leeds; A. J. Leslie-Spinks, Oxford and Westminster; A. L. Light, Leeds; C. M. MacGeoch, Birmingham; H. M. Mills, Royal Free; L. Milner, Guy's; G. P. Nixon, St. Bart.'s; J. P. O'Donnell, Leeds; L. G. M. Page, St. Bart.'s; A. J. D. Perkin, St. Thomas's; Alice D. K. Peters and H. G. Pritchard, Charing Cross; A. S. Rajasingham, Middlesex; R. G. E. Richmond and H. G. G. Robertson, St. Thomas's; R. S. Robinson, Middlesex; H. W. Round, Birmingham; I. A. Sabri, St. Bart.'s; M. V. Samuel, Adelaide and London; S. Schenkman, London; J. E. Schneider, St. Thomas's; D. A. Seaman, Birmingham; G. M. A. Shaikh, London; A. Southgate, Charing Cross; T. T. Stamm, Guy's; A. R. Thomas, St. George's; E. W. Thompson, Manchester; V. C. Thompson, St. Bart.'s; J. G. Thwaites, St. Thomas's; B. T. Utley, St. George's; H. D. Vasey, St. Thomas's; V. C. Verbi, King's Coll.; P. Wiles, Middlesex; G. W. Willcox, St. Thomas's; L. V. Williams, St. Bart.'s; Muriel Williams, King's Coll.; L. K. Wills, Guy's; W. A. Wilson, Univ. College; J. Winter, Middlesex; F. W. J. Wood and T. C. Yip, St. Bart.'s; and E. Zimbler, Middlesex.

Midwifery.—S. S. Ahluwalia, Lahore; Gulzar M. Ali, Royal Free; G. Allen, London; M. W. Atkinson, Middlesex; T. C. Baker, St. Mary's; H. F. Bateman, St. Bart.'s; W. A. G. Bell, Cambridge and St. Thomas's; W. A. Bellamy, St. Bart.'s; Mark Berkeley, Royal Free; Kathleen L. Bland, Univ. College; K. S. P. Blatchley, Edinburgh; N. J. Boulton, Guy's; G. H. Bradshaw, Cambridge and St. Bart.'s; J. V. Broad, Cambridge and St. George's; M. A. Chamberlain, Manchester; Rochelle Churin, Royal Free; A. M. Clarkson, Univ. College; W. A. Clements, Sheffield; Lilian M. C. Clopet, Cardiff; S. J. Cope, St. Thomas's; J. E. Curnock, Charing Cross; T. Dagger, Liverpool; K. K. Dalal, Middlesex; A. Danin, Guy's; H. W. Daukes and D. C. L. Derry, St. Thomas's; P. C. C. de Silva, King's Coll.; W. F. de Villiers, London; F. T. Doleman, St. Mary's; H. F. Ellis, Liverpool; W. T. Ellis, Manchester; N. B. Fadia, Bombay; M. Gamboa, St. Bart.'s; Agnes G. Gillespie, Liverpool; H. Gordon, Durham; I. Gordon, St. Bart.'s; C. Graham, Belfast; Valentina P. Guercken, Westminster; H. W. Guinness, St. Bart.'s; Hafizuddin, Charing Cross; A. G. J. Harris, St. Bart.'s; Violet L. de A. Hickson, Westminster; C. F. House, St. Thomas's; Esme I. Hyam, Univ. College; J. Ives, St. Mary's; D. Simmons, Manchester; U. P. Sinha, Calcutta and Patna; T. T. Stamm, Guy's; M. Sternfeld, Freiburg; L. Taylor, Sheffield; R. S. Thomas, Guy's; J. G. Thwaites, St. Thomas's; W. E. Tucker, Cambridge and St. George's; R. G. L. Waller, Westminster; P. Wiles, Middlesex; L. K. Wills, Guy's; Kathleen Wilson, King's Coll.; W. A. Wilson, Univ. College; F. W. J. Wood, Cambridge and St. Bart.'s; F. C. A. Wright, King's Coll.; J. M. Wrigley, Sheffield and London; and T. C. Yip, St. Bart.'s.

THE RATING OF HOSPITALS.—The Devonshire Valuation Committee recently convened a conference of representatives of rating and assessment committees, the object of which was to fix a uniform rate for the assessment of voluntary hospitals in the county. The assessments at present vary enormously, the lowest figure per bed being 3*s.* and the highest £4 4*s.* The county valuation officer suggested £3 per bed gross, but the conference decided that the amount should be 7*s.* 6*d.*, to include nurses' beds.—Mr. Walter Kewley, the house governor of Middlesex Hospital, has written a letter urging the total exemption of hospitals from local rates.

CONTINENTAL ANGLO-AMERICAN MEDICAL ASSOCIATION.—The annual meeting, the first since the late war, was held at the Hôtel de Paris, Monte Carlo, on May 1st, members attending from the whole length of the Italian and French Rivieras. Dr. R. Pryce Mitchell (Monte Carlo), who presided, explained the objects of the Association and acknowledged the debt of gratitude due to the hon. secretary, Dr. R. Sherwood-Dunn (Nice) for his successful efforts in resuscitating the Association. Dr. Sherwood-Dunn, in presenting his report, said he had visited Paris for a personal interview with Dr. R. Turner, a former hon. secretary, and other old members, and had endeavoured to communicate with the 122 medical men and women whose names appeared in the last issue of the Continental Anglo-American Medical Directory. The report was approved and it was decided to limit membership of the Association to persons of British and American nationality and to those possessing British and American qualifications who are rightfully practising in Europe or Northern Africa. The annual subscription was raised from 40 to 100 French francs. At a banquet held the same evening Dr. H. Warren Crowe, an hon. president, presented to Dr. Thomas Linn (in absentia), founder of the Association, on behalf of its members, an address and the latest edition of the Encyclopædia Medica. The evening concluded with a visit to the Russian ballets in the local theatre at the invitation of the directors of the Casino.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The Registrar of this College announces that a Charles Murchison Scholarship in Clinical Medicine will be awarded after an examination on June 26th, and that a Streatfeild Research Scholarship in Medicine and Surgery, tenable for three years, and valued at £250 per annum, is to be offered in conjunction with the Royal College of Surgeons of England. Further information will be found in our advertisement columns.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the College was held on May 1st, with Dr. Robert A. Fleming, the President, in the chair. Dr. James Thomson was introduced and took his seat as a Fellow of the College. Dr. John Bowes McDougall and Dr. Anna Justina Augusta Wilson were elected Fellows of the College.

Alfred Joseph Clark, Margaret Black Martin, David Taylor Hackie, Joseph Ryland Whitaker, and Mohamed Abd El-Hamid Gohar were elected Members of the College.

Dr. Robert Thin was elected a representative of the College on the Conjoint Committee of Management of the Triple Qualification.—Dr. William Russell was re-elected the representative of the College on the General Council of Medical Education and Registration.—The Lister Fellowship was awarded to Dr. Charles G. Lambie for his work on carbohydrate metabolism.

At an extraordinary meeting held the same day, Dr. Walter Tyrrell Benson was elected a Fellow of the College.

UNIVERSITY OF LONDON: *University College.*—A public lecture on Modern Trends in the Study of Animal Development will be given by Prof. R. G. Harrison, of Yale University, on Monday, May 21st, at 5.30 P.M. Prof. Elliot Smith, F.R.S., will preside and admission will be free without ticket.

BIOCHEMICAL SOCIETY.—The next meeting of the Society will be held on Saturday, May 12th, beginning at 11.45 P.M., in the Department of Brewing and Biochemistry of Fermentation, of the University of Birmingham.

UNIVERSITY OF LONDON GRADUATES' ASSOCIATION. At a meeting of the Council of this association, held on May 7th, it was resolved, nem. con., to support the re-election of Dr. E. Graham Little as representative of the University in Parliament.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society to be held to-day (Friday, May 11th), at 8.45 P.M., at the Miller General Hospital, Greenwich, Dr. Charles Thomson will give a presidential address on Intestinal Stasis: Its Effects and Treatment.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, May 15th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship.
WEDNESDAY.—8.30 P.M., DERMATOLOGY, SURGERY. Special Discussion on Treatment of Varicose Ulcers by Intravenous Injection. Openers: Prof. Sicard (of Paris) (Dermatology), Mr. Twistington Higgins (Surgery). Other speakers will include Sir Sidney Alexander, Dr. Goldsmith, and Mr. David Levi.
THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Annual General Meeting (at 4.45 P.M.). Election of Officers and Council. Cases: Dr. H. W. Barber: (1) Kaposi's Idiopathic Hæmorrhagic Sarcoma. (2) Morphœa with Root Distribution. Other cases will be shown. The Annual Dinner will be held at 7.45 for 8 P.M.
FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P.M.) Annual General Meeting: Election of Officers and Council. Cases will be shown. 8 P.M., OBSTETRICS. Annual General Meeting: Election of Officers and Council. Specimens: Mr. R. Christie Brown: A Case of Perforation of the Uterus, Following the Criminal Attempt to Induce Abortion in a Case of Tubal Pregnancy. Mr. J. Bright Banister: A Case of Ovarian Pregnancy. Mr. W. Gilliatt and Dr. R. M. Saunders: An Unusual Case of Interstitial Pregnancy. Short Communication: Dr. Everard Williams: Full-Term Pregnancy in a Patient with Grave Myelocytic Leukæmia. 6.30 P.M., ELECTRO-THERAPEUTICS. Annual General Meeting: Election of Officers and Council. Annual Dinner at 7.15 for 7.30 P.M. at the Café Verrey, Regent-street, W.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
The Annual General Meeting and Conversazione arranged for Monday, May 14th, has been postponed to Monday, May 21st. At 9 P.M. on this evening Sir Archibald Garrod will deliver an oration entitled "Lessons on Rare Maladies."

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.
THURSDAY, May 17th.—8.15 P.M. (at 11, Chandos-street, Cavendish-square, W.), preceded at 7.45 P.M. by a demonstration to illustrate the subject of the paper. Dr. George W. Bray (Medical Officer, Nauru, Central Pacific): Vitamin-B Deficiency in Infants—Its Possibility, Prevalence, and Prophylaxis.

LONDON CLINICAL SOCIETY.
THURSDAY, May 17th.—8.15 P.M. (at the London Temperance Hospital), Clinical Evening.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.
WEDNESDAY, May 16th.—3.30 P.M. (in the Great Hall of the British Medical Association, Tavistock-square, W.C.) Sir John Macpherson: Maudsley Lecture—The New Psychiatry and the Influences which are Forming It.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.
WEDNESDAY, May 16th.—7.30 P.M., Dr. H. Moore, D.Sc. The Mode of Formation of the Image in the Microscope. Mr. G. F. Marrion, M.Sc., and Dr. A. S. Parkes, Ph.D. The Effects of Inanition and Vitamin B Deficiency Upon the Testes of the Pigeon. Miss M. E. Shaw, M.Sc., and Dr. F. W. Rogers Brambell, D.Sc.: An Aberrant Ovary in a Frog.

ROYAL STATISTICAL SOCIETY.
TUESDAY, May 15th.—5.15 P.M. (in the Hall of the Royal Society of Arts, John-street, Adelphi, W.C.), Mr. D. Caradog Jones: The Cost of Living of a Sample of Middle-Class Families.

CHELSEA CLINICAL SOCIETY.
THURSDAY, May 15th.—8.30 P.M. (at the Hotel Rembrandt, Thurlow-place, S.W.), Dr. J. H. Ruffel and Dr. O. L. de Wesselow: Clinical Value of Biochemical Methods.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: Harvey Celebrations.
MONDAY, May 14th.—11 A.M., Reception by the King at Buckingham Palace. 3 P.M., Reception at the College. 6.30 P.M., Dinner given by Grocers' Company, Grocers' Hall, E.C. 9 P.M., Lady Bradford "At Home," 8, Manchester-square.
TUESDAY.—10.30 A.M., Demonstrations at University College; kinematograph reproduction of Harvey's original experiments. 1.15 P.M., Luncheon at St. Bartholomew's Hospital. 4 P.M., Tea and Exhibition at St. Bartholomew's Hospital. 9 P.M., Conversazione at Merchant Taylors' Hall.
WEDNESDAY.—10.30 A.M., Demonstration at University College. 6.30 P.M., Dinner by the President and Fellows of the Royal College of Physicians at the Guildhall.
THURSDAY.—Visit to Oxford. 8.30 P.M., Reception by the President of the Royal Society at Burlington House.
FRIDAY.—Visit to Cambridge.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, May 14th, to SATURDAY, May 19th.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. Clinical demonstration by Dr. Thomas Cotton on Tues., at 2.30 P.M.—ST. MARK'S HOSPITAL, City-road, E.C. Clinical demonstration by Mr. W. H. Gabriel on cases illustrating Diseases of the Rectum on Tues., at 5 P.M.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C. Clinical demonstration by Mr. Whiting on Thurs., at 1 P.M. The above are free.—INFANTS HOSPITAL, Vincent-square, S.W. Course on Diseases of Infants, afternoons only (second week).—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C. Intensive course—clinical and operative. Three weeks. All day.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Course in Psychological Medicine (third week).—NATIONAL HOSPITAL, Queen-square, W.C. Course in Neurology for two months. Particulars and fees from the Fellowship of Medicine.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. On Wed., at 5 P.M., Prof. Louise McIlroy will give the first of four lecture-demonstrations on Antenatal Diagnosis and Treatment. Further particulars from the Secretary.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, May 14th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Spastic Paraplegia (1).
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Risien Russell: The Significance of Muscular Atrophy.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Active Infective Diseases of the Central Nervous System (2).
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M. Sir Percy Sargent: Meningeal Tumours from the Surgical Standpoint.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY, Paddington, W.
THURSDAY, May 17th.—5 P.M., Prof. Hamilton Hartridge, F.R.S.: Poisoning by Coal Gas and Products of Combustion.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.
MONDAY, May 14th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M. Dr. Trevor Davies: Gynæcological Department.
TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose, and Ear Department.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Department.
FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Children's Medical Out-patients.
TUESDAY, May 15th.—4.30 P.M., Special Lecture, Mr. Sinclair: Gall-stones.
Daily, 10 A.M. to 5 P.M., SATURDAYS, 10 A.M. to 1 P.M., In-patients, Out-patients, and Special Departments. Anæsthetic and Operative Surgery Courses.

ADWICK PUBLIC LECTURE.
TUESDAY, May 15th.—8.15 P.M. (at the House of the British Medical Association, Tavistock-square, W.C.), Major Walter Elliot, M.P.: Sunlight—Natural and Manufactured—Its Use in Modern Medicine.

IVERSITY COLLEGE, Gower-street, London, W.C.
TUESDAY, May 15th, THURSDAY, May 17th, and FRIDAY, May 18th.—Prof. L. H. Henderson (Harvard): Blood, a Study in General Physiology.

YAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, May 15th.—3.15 P.M., Mr. C. C. Choyce: Some Reflections on Tumours of the Breast.

STITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, May 16th.—3.30 P.M., Prof. J. W. H. Eyre: Rheumatism from the Bacteriological Viewpoint.

RTH-EAST LONDON POST-GRADUATE COLLEGE, rince of Wales's General Hospital, Tottenham.
MONDAY, May 14th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Tuesday and Friday, at 2.30 P.M., there will also be demonstrations of Surgical Cases and Cases for X Ray by Mr. W. E. Tanner and Dr. S. C. Shanks respectively.

NDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 9, Leicester-square, W.C.
MONDAY, May 14th.—5 P.M., Dr. J. E. M. Wigley: Napkin-Area Eruptions in Infants.
TUESDAY.—5 P.M., Dr. H. M. MacCormac: Treatment of Syphilis.
THURSDAY.—5 P.M., Dr. I. Muende: Pathology Demonstration.
FRIDAY.—5 P.M., Dr. K. Sibley: Alopecia.

IVERSITY OF BIRMINGHAM.
THURSDAY, May 17th.—4 P.M., Dr. L. G. Parsons: Recent Advances in Our Knowledge of Rickets and Allied Diseases. (Last Ingleby Lecture.)

NCHESTER ROYAL INFIRMARY POST-GRADUATE OURSE.
TUESDAY, May 15th.—4.15 P.M., Dr. A. Ramsbottom: Treatment of Pernicious Anæmia.
FRIDAY, 4.15 P.M., Mr. W. H. Hey: Demonstration of Surgical Cases.

IVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, May 8th.—3.30 P.M. (at the Royal Hospital), Dr. Skinner: Neurological Cases.

Appointments.

KWOOD, J. F., M.B. Lond., F.R.C.S. Eng. & Edin., has been appointed Resident Medical Officer, Farnborough Hospital, Kent.
ILL, H. M., M.B., B.Ch. Edin., Assistant Medical Officer to the Stokesley, Yorks, Board of Guardians.
ifying Surgeons under the Factory and Workshop Acts: DAWSON, R., M.B., Ch.B. Aberd. (Middleton-in-Teesdale); WARD, K. L. S., M.B., Ch.B. Edin. (Westerham); and DOYLE, J. L. C., L.R.C.P. Lond., M.R.C.S. (Fakenham).

Vacancies.

The following vacancies for Certifying Factory Surgeons are announced: Kirkwall (Orkney), Halstead (Essex), and Lewes (Sussex).

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On May 4th, at Avenue-road, N.W., the wife of Dr. F. Shirley Adams, of a daughter.
BEVAN.—On April 30th, at a nursing home, the wife of Dr. Frank A. Bevan, of Hadleigh, Essex, of a daughter.
GIBSON.—On May 4th, at Amalfi, Kents-road, Torquay, the wife of Dr. Paul Currey Gibson, of a daughter.

MARRIAGES.

FINNY—MANNERS SMITH.—On April 30th, at St. George's Church, Camberley, Major Charles Morgan Finny, O.B.E., R.A.M.C., to Doris Manners Smith, daughter of the late Lieut.-Colonel John Manners Smith, V.C., C.V.O., C.I.E., and Mrs. Manners Smith, Home, King's Ride, Camberley.

DEATHS.

ELLIOTT.—On April 28th, at Broad-street, Stamford, George Elliott, L.R.C.P., L.R.C.S., aged 65.
FENN.—On May 3rd, at Ashley Park, Rusthall, Tunbridge Wells, Joseph H. Fenn, M.R.C.S., L.R.C.P., late Captain, R.A.M.C.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE HOSPITAL OF ST. MATTEO, ZARA.

THE writer of the article on Yugoslavia, which appeared last week in THE LANCET, sends us a description of this institution in Zara which he visited while on the tour. He points out that it would have been inconvenient to include an inspection of St. Matteo in an article dealing with Yugoslavia, inasmuch as that country and Italy manifest such reluctance to be associated in the minds of Europe. Zara and a few miles of territory to the east of it are, of course, in an Italian enclave on the Adriatic coast. "A section of the touring party," writes our correspondent, "complied with the necessary passport formulæ and went up from Sebenico to Zara. It was necessary to leave their car outside the city and enter by cabs which had been telephoned for to meet them on the frontier. In the city of Zara they were met by the Prefect, by Major Grant Smith, an English resident, and other representatives of science and business, and were conducted round the interesting city, when they had the good fortune to have an excellent cicerone, whose descriptions of the cathedral, the old noble residences, the fortifications, and harbour made clear why the possession of Zara has always played a part in political and military contests. But from the medico-social point of view the institution of the greatest interest offered by Zara proved to be the Hospital of St. Matteo, a shelter for aged and indigent women, owing its foundation to the generosity of a wealthy citizen named Pavaz. This handsome building, situated on the Cereria, just without the walls of the city, stands in large and well-kept grounds and interiorly is a model of cleanliness and good arrangement. The funds are administered by the Congregation of Charity, with a resident Sister Superior and a lay president; and public statements are made from time to time as to the care of the inmates. Such refuges for subjects who form a particularly difficult charge upon health authorities might well be instituted by charitable folk in this country, and the St. Matteo Hospital at Zara would be a good model."

POLYNEURITIS COMPLICATING MUMPS.

NEUROLOGICAL complications of epidemic parotitis are not uncommon, but it is rare to find diffuse polyneuritis following this infection. In a case recently published by Dr. W. S. Collens and Dr. M. A. Rabinowitz [1] the patient was a man of 29 who had a mild attack of mumps followed a week later by orchitis. Three weeks after the onset of mumps he felt weakness in the legs, and in 48 hours was almost unable to move; besides quadriplegia he had complete bilateral upper and lower facial paralysis. No reflexes, deep or superficial, could be elicited, and after another day he complained of hyperæsthesia of the hands and feet. About a week later he showed signs of returning control, and about four months from the onset he was perfectly well again. The authors quote four previous cases, which are all they have been able to find in the literature; in each of them, as in their own, the picture resembled the condition seen in other specific fevers and in poisoning by alcohol and lead. Flaccid paralysis of the extremities, loss of both deep and superficial reflexes, slight or no sensory disorders and disturbance of muscle and joint sense were common to the five cases. All the patients recovered completely after illnesses lasting for 1–12 months. Whilst this alarming syndrome is too rare to be of much clinical importance, it raises once again the interesting question why such a complication should affect some patients and not others.

THE SCHOOL-BOY'S HOWLER.

THE familiar school-boy howler does not arouse in the minds of most people much curiosity into the causes of juvenile malapropisms. Sir John Adams. however, attempts a scientific investigation [2] into the causes of these amusing and instructive phenomena. Close scrutiny of the atmosphere of the class-room throws light upon the child's errors. The over-zealous teacher may be led to the belief that his function is to impart knowledge at all costs. He may take delight in so doing and may be completely carried away by his own flow of pedagogic eloquence. Indeed, according to Sir John Adams the pedantry that grows out of excess of method is manifest in the rigid adherence to rule even of such apparently broad and free methods as those of Froebel and Montessori. Unless the peculiarity of the mental life of the child be taken into account, unless the teacher identifies himself with the child's mental world, modifying hi vocabulary and seeing the child's needs, he will find tha the knowledge he has imparted has been twisted into th youthful mould and will, when re-evoked, appear grotesquel distorted. It is the duty, therefore, of the teacher to buil a bridge from this inner world to that world of organise experience which adult and realistic thinking has constructed To achieve this the teacher must have explored the processe of the one and the collective and systematised data of th other.

Sir John Adams has written an enlightened and instructiv book, illuminated with flashes of humour and a warr humanity.

RELATION OF THE THYROID GLAND TO THE NASAL MUCOUS MEMBRANE.

THE theory has been put forward that a common embryc logical origin has imposed on the thyroid gland and th nasal mucous membrane a common response to stimul Dr. Giuseppe Calogero, of the University of Naples, ha lately published [1] some experiments which are intended t establish the reality of the connexion between the tw He operated on a dog and five guinea-pigs by cauterisin the nasal fossæ with a weak nitric acid solution on a fir red hot iron wire. The animals were afterwards killed, an on examining the thyroid gland Dr. Calogero found hist logical changes from which he infers that the stimul produced by the cauterisation gives rise in the first instan to an increase in the secretory activity of the thyroid, an secondarily leads to phenomena of hyperplasia in th lining cells of the acini, presumably through the medium the sympathetic nerves which connect both the nas mucosa and the thyroid gland to the cervical tract of th sympathetic.

DOMESTIC BIOLOGY.

AN admirable account [2] of the various small anima which are likely to interest students of domestic science ha recently been written by Miss P. Esdaile, D.Sc. The tit is a little misleading, for the book contains nothing abo vertebrates which certainly include a number of "harmf and useful animals." She deals, however, with protozo worms, insects, spiders, and mites, and describes those whi produce familiar articles (e.g., the bath sponge and th silkworm moths) and those which are pests (e.g., cockroache wood-boring beetles, clothes moths), indicating at the san time appropriate methods of control of the spread of th latter group. In small details the book is open to a fe criticisms; it is, for example, hardly correct to descril *Xenopsylla cheopis* as a "parasite" of man (p. 70) ar *Ptinus* would be easier to recognise (p. 119) if he was show sideways; the theoretical morphology on pp. 28–29 is o of place. But we know of no other book which covers ju the same ground, and it should certainly find a place in th library of every housewife who wants to understand h job; district nurses will also find it useful.

THE YEAR OF AMBROISE PARÉ'S BIRTH.

Dr. Herbert Spencer writes: In my Lloyd Rober Lecture, 1924, I stated: "As with the founder of this lectur there seems to be a doubt about the actual date of Paré birth, the years 1509, 1510, 1514, 1516, 1517, 1528 havi been given by various authors. Malgaigne, 'Œuvres cor plétes d'Ambroise Paré,' 1840, states, on the authority Bégin, that 'A. Paré was actually born in 1517.' H would thus be 73 and not 80, as usually stated, at the tin of his death." I was unable to obtain access to the eviden on which Bégin based his statement. It is to be hoped th some French medical historian will settle the date of t birth of the great reformer of surgery and midwifery.

A HOME FOR DISSEMINATED SCLEROSIS.

"PERPLEXED" writes:—I should be very grateful if a of your readers would tell me of a home which would recei a middle-aged patient of mine suffering from disseminat sclerosis. She could only afford to pay 3 or 4 guineas a wee

A CORRECTION.

Dr. SPENCER MORT writes:—A short time ago I sent communication to THE LANCET (1927, ii., 1341) on t Value of Sodium Tetra-Iodo-Phenolphthalein. . . . In was a statement that a patient had been "referred to r recently by Mr. James McClure for diagnosis and treatment Mr. McClure tells me this is not so, and at his wish I wr to ask if you will kindly insert this correction.

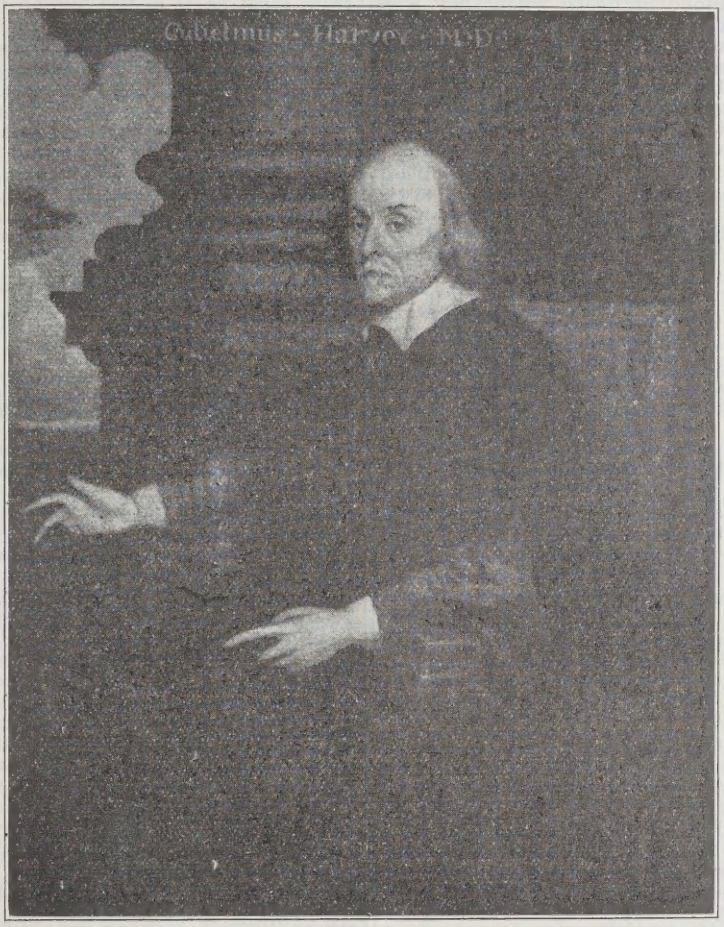
LIBRARY UNIVERSITY OF ILLINOIS URBANA

An Appreciation OF HARVEY AS ANATOMIST.

Prepared for the Harvey Tercentenary Celebration

BY SIR ARTHUR KEITH, M.D. ABERD., F.R.S., PRESIDENT, BRITISH ASSOCIATION; CONSERVATOR OF MUSEUM AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To understand how any given masterpiece of art s come into existence we must have access to the udies, sketches, and ideas which preceded its execu-on. It is also so in the case of great inventions; it not the finished echanism which terests the ident of dis-very, but the rude first tempts and the perfect models the inventor. is also so in e world of bio-gical discovery; arvey's master-ece "De Motu rdis," is the ost perfect thing the annals of ological dis-very, but it is ly the com-eted picture we ve—the one ich he gave to e world—after had laboured it for a quarter a century. No-ere, unfortu-tely, does he l us what set n off on his est, nor the der of events ich convinced n that he was ht and all the st of the world ong. We may certain, I think, at his inspira-n and his first es came to him he learned to e scalpel, for-os, and probe in e pursuit of atomy.



WILLIAM HARVEY.

From the portrait belonging to the Royal College of Physicians of London.

When Harvey was studying in Padua, his aster, "the celebrated Hieronymus Fabricius of quapendente, a most skilful anatomist and venerable d man," was preparing his monograph on the valves the veins (published in 1603), and his pupils must ve had their attention concentrated on these echanical contrivances. A keen student is always tracted to subjects investigated by his teacher. bricius taught, as was accepted by all of his day, at the blood in the veins flowed outwards from e heart to the periphery and that valves had been in the walls of veins to regulate the distribution blood to dependent parts. Now, we see that at ery point of his final argument Harvey accepts the ctum of Galen—as all anatomists must still do—at Nature is the perfect contriver. "For Nature ways does that which is best," Harvey says in e passage; "Nature does nothing in vain" he writes in another; "Nature ever perfect and divine" in a third. "But is not the thing rather arranged as it is by the consummate providence of Nature?" is a question he puts to his reader. If Harvey thought thus he must have perceived that, in setting valves in the veins, with their catching edges directed towards the heart, either Nature had blundered or his teacher Fabricius had misread Nature's design. Often the young inquirer makes a flaw in his teacher's argument the point of departure for his own research, and it is probable that this was the case with Harvey. The first clue that put him on the track of his great discovery was probably his search for an explanation of those minor structures—the valves of veins. How soon he took to examining the action of valves as revealed in the distended veins of the living arm and that in life they prevented any kind of reflux, we cannot say. In this, as in all other instances, he never failed to put anatomical conjecture to the test of physiological proof. Herein we see that Harvey was that very rare kind of man—the perfect anatomist.

Long before he left Padua it must have dawned on Harvey that all was not well with the doctrine which the leading anatomist of the day taught his pupils concerning the uses of the heart and of its great vessels. If "Nature had made nothing in vain," why had such a useless structure as the right ventricle, "an apparatus of fibres, braces, and valves," been added to the heart? Why should there be placed within the heart and in the pulmonary artery and aorta contrivances which were as perfect in their mechanical action as the "clacks of a water bellows"? If the heart was, as Fabricius taught, merely a vat in which blood was concocted and vital spirits brewed, such structures were purposeless. And why should the lung require such an enormous blood-supply? Fabricius could explain none of these things and the first duty of an anatomist is to explain.

At several points of his argument Harvey makes statements which suggest that there was another and weightier reason which caused him to be dissatisfied with what Fabricius taught concerning the action of the heart. In Chapter V., and again in Chapter VI., he states that "the grand cause of doubt and error in this subject (the circulation of the blood) appears to me to have been the intimate connexion between heart and lungs." One may infer from this statement that the first real step in Harvey's discovery was a realisation of what was the exact nature of the relationship which existed between heart and lungs.

The way had been prepared for him by Servetus and Columbus; both held the heretical opinion that there were passages in the lungs by which blood passed from the right ventricle to the left. In this matter Fabricius was orthodox. He taught Harvey that the pulmonary artery supplied the lungs with nourishment and that the pulmonary veins served as pipes or passages—first, for the conveyance of air from the lungs to the left ventricle; and, secondly, for the return of fuliginous vapours from the left ventricle to the lungs. The mitral valve, Fabricius held, was designed to prevent the regurgitation of air once it had entered the left ventricle. "Good God," demanded Harvey, "how should the mitral valve prevent the regurgitation of air and not of blood?" And why, if the pulmonary veins were for the conveyance of air had they not the rigid walls of the windpipe? And why should they be filled with blood at death when they were charged with air in life? And why was it, when lungs were inflated in a living dog or in a dead man, that air never passed into the pulmonary veins and left ventricle? Fabricius could explain none of these things. Harvey could explain all if he were allowed to presume that there were "pores" in the lung by which blood could pass from pulmonary artery to pulmonary vein. Such an assumption he claimed to be legitimate, for did not everyone allow that blood percolated through liver and kidneys? If blood could pass through the dense substances of these organs why, asked Harvey, cannot it not find its way through the porous texture of the lungs?

Study of the Living Heart in Action.

All the men who taught Harvey agreed that the blood was formed in the liver, and that somehow it was conveyed from the right side of the heart to the left. The accepted opinion was that it passed by "secret pores" through the interventricular septum. "But, by Hercules!" exclaims Harvey, "no such pores can be demonstrated, nor in fact do any such exist. For the septum of the heart is of a denser and more compact structure than any portion of the body, except the bones and sinews." Harvey here again appeals to his argument from Nature. He points out that in the fœtus, where the lungs are silent in function, Nature has opened a passage whereby blood can pass direct from the right side of the heart to the left; if she had intended that blood should pass from right to left side of the heart, not through the lungs, but direct from ventricle to ventricle, she would certainly have provided an ample and unmistakable passage.

Anatomical conjecture can only give a clue to function; it can never provide the final and convincing proof. At what point of his inquiry Harvey discovered that the heart was a pump—a double pump, the right ventricle attached to the lungs and the left to the rest of the body, we do not know, but it is certain he could never have made this discovery unless he had studied the heart in action within the living body. Harvey's mode of thinking was his own but his methods of inquiry he owed to Fabricius. It was from his master that he learned to resort to embryology, to comparative physiology, and to vivisection when in search of evidence needed for the elucidation of all the problems of structure. It was to Fabricius he owed his faith in comparative physiology. What was found to be true of higher animals was certain to be directly applicable to the case of man. For Harvey, blood and spirit were one and inseparable; so were anatomy and physiology. He found the heart a mass of anatomical incongruities; by making physiology the handmaid of anatomy he was able to leave it a perfectly explained organ. Anatomy provided him with suggestions; physiology furnished him with the proofs.

Rescue of Medicine from the Demonology of Myth.

There is nothing more difficult for us moderns than to feel a pulse with the finger of a pre-Harveian physician. Under his finger the artery expanded of itself, drawing in blood, spirits, air and vapours of all sorts and squeezing them out again as it contracted. We feel only Harvey's stroke of the heart—the arterial distending as "when a bladder is filled." We see the patient's body as a great capillary field, uniting arteries and veins—a field of whose existence Harvey knew nothing save by inference. We think in terms of oxygen, carbon dioxide, and combustion; even Harvey had to content himself with "vital spirits," "fuliginous vapours," and "innate heat." To the pre-Harveian physician the human body was a realm dominated by a cosmogony of spirits; Harvey's greatest service to medicine was not the discovery of the circulation, but his rescue of medicine from the demonology of myth. As his method of inquiry came into fashion spirits became more and more obsolete and less and less used by anatomists for the purpose of explanation. The spirit myth has now departed from most parts of the human body, save the brain where it still lingers.

Even Harvey himself was clearly staggered by one aspect of his discovery. When he had measured the capacity of the left ventricle and calculated its output, the amount seemed to him unnecessarily great. He found that in half an hour, with the heart beating 70 to the minute and only throwing out half an ounce at each stroke, that more than eight gallons of blood would have circled round the body. If blood was merely for the nourishment of tissues why was so much needed? Harvey supposed that such rapid circulation was needed to keep tissues supplied with heat and vital spirits, and that the blood would congeal and thicken if not kept in active movement. More than a century after Harvey's death vital spirits were replaced by oxygen.

Harvey and Darwin.

There is a very remarkable parallel between the discoveries of Harvey and of Darwin—although the two men represent very different physical types of Englishmen. Both put forward a hypothesis to explain an enormous number of biological facts—the one to prove the truth of the circulation, the other to prove the truth of evolution. Before Harvey other men had thought of circulation of the blood, and before Darwin there had been many evolutionists. But whereas the efforts of their predecessors had been tentative and not fully convincing, so overwhelming was the proof they brought forward in support of their contentions that the resistance of men's minds was overborn and what had been heterodox became suddenly orthodox. Both Harvey and Darwin began by conjecture and ended by resorting to experimental proof. In both cases a large presumption had to be made; Harvey had to presume that passages existed between arteries and veins throughout the body; Darwin had to presume that there was a biological process by which the specific characters of any kind of living thing could be altered so that a new species was produced. Such presumptions had to be made by both men; only by making them could all the facts be explained. Within three years Malpighi saw through his microscope the passages which Harvey had seen only by the eye of faith; but although Darwin has been dead these 44 years, his Malpighi has not yet made his appearance. Some day he, too, will arrive.

THE LATE DR. T. D. NICHOLSON.—After a short illness, Dr. Thomas Dryden Nicholson died at Brampton near Penrith, on April 29th. Sixty-four years of age, he was a Cumberland man and was educated at Blencowe Grammar School. His medical studies were pursued at the University of Edinburgh, and he graduated there M.B. in 1890. After several years spent at Bolton-le-Dearne, in Yorkshire, he settled in 1899 at Shap, where for 21 years he carried on a practice covering a wide and thinly populated area. Not only as medical officer and practitioner but also as a public-spirited and active worker in many causes, he was well known throughout the district, and in 1912, he was appointed a magistrate for the county. About seven years ago Dr. Nicholson moved to Brampton. He leaves a widow with two sons and two daughters.

THE COST TO THE COUNTRY OF INDUSTRIAL RHEUMATISM.*

By Sir WALTER S. KINNEAR, K.B.E.,
CONTROLLER OF HEALTH AND PENSIONS INSURANCE, MINISTRY OF HEALTH.

THAT rheumatism has long occupied a large place in the nation's burden of sickness is a matter of common knowledge, and probably even persons unaccustomed to the study of public health questions would not be surprised to learn that a conference has been convened for the discussion solely of rheumatism in its various forms. What has probably been a matter for surprise, even to persons with expert knowledge of the subject, is the extent of the invalidity now known to follow from rheumatic disease, as evidenced by the data which have become available during the last few years. Rheumatism, it was recently been remarked, is now a social as well as a medical question, and the setting apart of a section of this conference for the discussion of its social aspects implies recognition of this fact.

The health insurance system has been of value in adding to our information as to the extent of the prevalence of rheumatism. In 1921 an investigation was made consisting of an examination of a section of the records of 226 insurance practitioners having between them some 400,000 insured persons on their lists, with a view to ascertaining the relative frequency with which insured persons consult their doctors for a number of illnesses, classified in broad groups. In a list of 15 "diseases" causing insured persons to consult their doctors rheumatic complaints came third in order, the number of cases per 1000 illnesses of the most common diseases being: bronchitis, &c., 213; digestive system, 131; rheumatism, lumbago, &c., 88.

The Incidence of Rheumatic Diseases.

Of most value in relation to the subject now under discussion, however, is the report of the Ministry's Committee on the Incidence of Rheumatic Diseases published in 1924. This report is based upon a detailed examination of the illnesses of a rheumatic character during 1922 among all insured persons on the carefully recorded lists of 49 insurance practitioners. The number of insured persons on such lists was approximately 58,000 males and 33,000 females—i.e., 91,000 in all. The number of rheumatic cases among the illnesses recorded in the year was 2510, of which 1771 related to males and 739 to females. With the aid of the material derived from this small but valuable sample the Committee estimated, broadly, the proportion of sickness due to rheumatism among the insured population and the cost of this sickness in health insurance benefit. Having regard to the fact that the insured population numbers over 15,000,000 persons and includes practically all the wage-earning classes between the ages of 16 and 65 (until this year between 16 and 70), it may be said to approximate closely to the mass of industrial workers of the country. Accordingly I propose to estimate the cost to the country of industrial rheumatism by applying the conclusions of the Committee to the most recent sickness experience of insured persons in Great Britain which is available—viz., that for 1927. It must be kept in mind, however, that the figures which I shall presently give relate only to the insured wage-earners. It is to be regretted that they do not cover the invalidity of wives or non-wage-earning dependents of insured persons, nor that of men and women over the age of 70.

It must be remembered that the Committee's estimate of the amount of invalidity due to rheumatism must be accepted with one important reservation. With the object, quite properly, of excluding any sickness as to the origin of which there was any element of doubt, the Committee, unless arthritic or fibrositic symptoms were present, took no account of chronic heart disease, of which it is estimated that at least one-half is rheumatic in origin. We are told in the Ministry's recent report on Acute Rheumatism in Children, published in May, 1927, that probably not less than 40 per cent. of all deaths from heart disease have their origin in acute rheumatism and two-thirds of the acute rheumatic infections which ultimately cause those deaths are contracted in the period of childhood, 5 to 15 years. The Committee, being concerned with the insured population (i.e., at that time persons between 16 and 70), would have no cognizance of cases diagnosed in the period under review as "heart affections," and thus some portion of the total invalidity due primarily to rheumatism has doubtless escaped observation.

Rheumatic Diseases in Various Age-groups.

Some idea of the extent to which the factor of age enters into the question of rheumatism can be obtained from the following comparison in the Committee's report of sickness per annum due to all rheumatic diseases per 100 insured persons in each age-group (Table I.).

TABLE I.

Age-group.	Days of sickness per annum per 100 insured persons in each age-group. All rheumatic diseases.	
	Males.	Females.
16 to 24	27	58
25 to 34	30	74
35 to 44	95	124
45 to 54	243	390
55 to 64	457	1026
65 and over	2007	3190

The division of these figures into three broad disease-groups (Table II.) is still more illuminating.

TABLE II.

Group A.—Acute and subacute rheumatism.
" B.—Non-articular rheumatism.
" C.—Chronic joint diseases.

Age-group.	Days of sickness per annum per 100 insured persons in each age-group. All rheumatic diseases.					
	Males.			Females.		
	A	B	C	A	B	C
16 to 24	20	5	2	41	8	9
25 to 34	12	13	5	28	9	37
35 to 44	24	32	39	24	51	49
45 to 54	34	74	135	57	107	226
55 to 64	22	148	287	71	252	703
65 and over	51	593	1363	139	790	2261

It is to be noted that the amount of sickness due to acute and subacute rheumatism (Group A), while being comparatively heavy at the youngest ages, and costing the insurance funds a large sum of money because it affects the most numerous section of the industrial population, is much lighter than that due to other forms of the disease at all ages over about 40. Sickness due to non-articular rheumatism (Group B) increases quite substantially with age, while that due to chronic joint diseases (Group C) increases in a most marked manner.

TABLE III.

Group.	Men.	Women.
A. Acute and subacute rheumatism	14 per cent.	24 per cent.
B. Non-articular rheumatism ..	32 "	23 "
C. Chronic Diseases	54 "	53 "

The relative prevalence of the various groups of rheumatic diseases for insured persons in each sex can be seen from Table III.

* Communicated to the Bath Conference on Rheumatic Diseases.

Sickness and Disablement Benefit due to Rheumatic Disease.

One of the most interesting conclusions of the Committee, and one to which I desire to direct your especial attention, is to the effect that in the year under observation approximately one-sixth of the total period for which sickness and disablement benefit was paid to men was due to rheumatic diseases. The corresponding figure for women was one-seventh. An examination of the records of certain individual approved societies produced an almost similar result. Since 1922, however, the amount of invalidity under the National Health Insurance Act has risen, the increase being more marked in the case of disablement benefit (i.e., illnesses with a duration exceeding six months) than in the case of sickness benefit (i.e., first six months of illness). It may be that, with the increase in the proportion of protracted sickness, the portion of the total attributable to rheumatism is now a little different from what it was in 1922.

Estimated Cost of Rheumatism in 1927.

It is probable, however, that these two fractions, one-sixth (men) and one-seventh (women) are still sufficiently accurate for my broad estimate of the cost of industrial rheumatism. In 1927 the total sickness and disablement benefit payments made by approved societies in England, Scotland, and Wales amounted to about £20,000,000. This represented about 34 million weeks of incapacity for which benefit was paid. If due allowance be made for incapacity occurring in the initial period of sickness, when no benefit is payable (i.e., the waiting days), it is probable that the total incapacity amounted to about 35 million weeks, the proportion due to rheumatism being about 5½ million weeks. The corresponding cost of medical services and the administration of insurance committees and approved societies in 1927 was about £14,000,000. If we allocate something over one-half of the cost of administering approved societies to the supervision of sickness and disablement benefits, and if, further, we take a fraction a little under one-sixth (to allow for women) and apply the result to both sickness and disablement we arrive at a figure of a little over £5,000,000 as the approximate disbursements made under the national health insurance scheme in Great Britain during 1927 on account of rheumatism.

If to the foregoing we add the amount of wages lost to insured persons through rheumatism on the basis of an average wage of from 50*s*. to 55*s*. per week (man) and from 25*s*. to 30*s*. per week (woman) the £5,000,000 requires to be increased by about £12,000,000, making a total of £17,000,000 in all. This vast sum then represents approximately the yearly disbursements under the national health insurance scheme to insured persons on account of rheumatism together with the accompanying loss of wages. It does not include any sum for the cost of the medical treatment of persons suffering from rheumatism who are not totally incapable of work, of the cost of nursing in bad cases, nor does it take account of the cost of any necessary institutional treatment. Further, it does not cover fully persons over the age of 70, the relative cost in respect of whom must be heavy in view of the rapid increase in the severity of the disease with age, nor does it make any allowance for dependents of insured persons, all of which, if it were possible, should be taken into account in assessing the cost of rheumatism to the country.

Conclusion.

This necessarily brief survey of the cost to the country of industrial rheumatism will, I trust, enable the Conference to gain a fuller realisation of the extent of the invalidity now known to be definitely traceable to rheumatism, and will, I hope, result in a further stimulus being imparted to the efforts which are being made to investigate its causation and methods of treatment, with a view to ameliorating the disquieting incidence of the disease.

THE "RHEUMATIC DISEASE."*

BY DR. FERNAND BEZANÇON,
PROFESSEUR DE CLINIQUE MÉDICALE À LA FACULTÉ DE MÉDECINE DE PARIS;
AND
DR. MATHIEU-PIERRE WEIL,
CHEF DE LABORATOIRE À LA FACULTÉ DE MÉDECINE DE PARIS MEDICIN DES HÔPITAUX DE PARIS.

AMONG the heterogeneous collection of condition grouped together as rheumatic, there is one clinica type which seems to us to possess characteristi features, and which we believe to be an independen disease entirely distinct from such other acute join lesions as may be produced by gout, infective arthriti or chronic rheumatic conditions. This is acut articular rheumatism, characterised by lesions of th joints, multiple, shifting, and transitory, which subsid without leaving any trace, and cardiac manifestation which, on the other hand, persist, become permanen and chronic. This acute polyarthritis is called i France acute articular rheumatism, the rheumati disease or Bouillaud's disease, after the great Frenc clinician who identified it in 1840.

Though the symptomatology of acute articula rheumatism and its cardiac manifestations are we known, we are still unacquainted with its ætiology The infective origin of the condition appears certain but it has not yet been possible to demonstrate th specific pathogenicity of any bacterium or mor complex parasite. A certain number of physician still consider that the disease only develops in particular soil—viz., the arthritic diathesis. Sinc bacteriological evidence has proved inconclusive, w have, during the last few years, attempted to invest gate the true nature of the disease by grouping a the available information on its ætiology, symptom tology, and complications.

Acute Articular Rheumatism and Arthritism.

It seems to us right to refuse to accept any connexio between acute articular rheumatism (Bouillaud disease) and the arthritic diathesis. The relationshi which has been ascribed to acute articular rheumatism applies in our opinion to polyarthritic conditions whic are really gouty in origin, due either to true gout o its atypical forms.

In 84 patients carefully studied from this aspec we only found one case in which the father of th patient was asthmatic, and the mother suffere from migraine; in all the other cases the disea supervened in subjects in whom there was no persona or hereditary evidence of the arthritic diathesis Chronic rheumatism, gall-stones, gout, diabete eczema, hæmorrhoids are exceptional in person affected with acute articular rheumatism. Beside this disease affects the hospital class of patients rathe than the private class, and it is among the latter tha the arthritic diathesis is much more prevalent.

If gout is the disease of the rich, *morbus dominum* Bouillaud's rheumatic disease afflicts on the contrary a social classes, but mainly the working classes and th poor.

Infectivity of Acute Articular Rheumatism.

The infectivity of acute articular rheumatism wa recognised by Stoll, Lanceraux, Thoressen, Feldkamp and Friedland. Chomel, Hirsch, and Lange (o Copenhagen) have described definite epidemics, d la Harpe described an epidemic at Lausanne in 184(Lebert one at Zurich in 1857, and Warrentrap one a Frankfort in 1865. Mantle, Edlefsen (at Keil), an Sweifel described epidemics in houses or road Ch. Fies found evidence at Oyonnax that rheumatism like tuberculosis affected certain dwellings. Th subject has been reconsidered in the light of abundan statistics by St. Lawrence and Faulkner and White.

According to St. Lawrence, in 50 per cent. of the famili of rheumatic patients two or more persons affected wit

* Communicated to the Bath Conference on Rheumat Diseases.

LIBRARY UNIVERSITY OF ILLINOIS

neumatism can be found; of 480 persons exposed to the nfection, 14·8 per cent. were found to be affected; this roportion is higher than that observed in tuberculosis. he frequent occurrence of rheumatic heart disease is enerally recognised; thus, in 22 families out of 50 examined y this author two members were affected with cardiac isease, in five families three members, and in two families our members—i.e., in 29 families out of a total of 50, two r more members were affected with heart disease. Of the 80 persons exposed to the infection 38 had a cardiac lesion, aking 8 per cent., which is a much higher incidence than n the general population among whom the incidence is sually estimated at 1–2 per cent. According to St. awrence the familial incidence of acute articular rheumaism is higher than that of tuberculosis. Faulkner and Vhite have also reached analogous conclusions. Studying 1 families of rheumatic patients they found that in 35·5 er cent. of the cases more than one member of the family ere affected; of 1235 persons exposed to the infection, 79 per cent. were attacked.

During the discussion which followed the publiation of these results, Wilson stated that he had ound that 40 per cent. of the patients affected with neumatism were the children of rheumatic persons, nd that in 28 per cent. of the cases their brothers and sters were also affected with the rheumatic disease. Ve, on our part, before we knew of this research, had ttempted to obtain similar statistics. As a matter f fact, simple questioning will often fail to elicit hether the joint lesions described in the history are uly rheumatic or whether they are merely painful onditions which have nothing in common with this isease, except that they affect the joints. But among ll joint diseases, acute articular rheumatism is disnguished by its affinity for the heart. It is, therefore, the frequency of heart disease in the families of ur patients that we have attempted to ascertain.

In 23 families of rheumatic patients whose histories e have been able to obtain, there was no evidence of rdiac disease in the parents or collaterals; it occurred, owever, in seven other cases—i.e., in 30 per cent. of our atients. Twice the mother was suffering from chronic alvular endocarditis, twice the father, once the sister, nd once the grandfather and grandmother, and once ther, mother, and a brother and sister; the familial nature f the disease was particularly evident in this case.

Entourage of Rheumatic Patients.

Thus, our statistical results are lower than those f St. Lawrence, but comparable with those of aulkner and White. It seems to us, however, that n the families of persons free from rheumatism, acute rticular rheumatism and valvular heart disease are uch more frequent than these authors state. We xamined from this point of view the families of 3 non-rheumatic individuals chosen at random om the in-patients suffering from acute diseases n our department of the Boucicaut Hospital. In 3 of these cases there was no rheumatism or cardiac isease in the ascendants, collaterals or descendants. n the other hand, in six cases—i.e., 17 per cent.—he existence of the rheumatic disease was most robably present in the immediate family of these on-rheumatic patients. Thus, in the entourage f rheumatic patients the incidence is approximately vice as great as in the non-rheumatic. The conagiousness of the rheumatic disease is therefore istinct; it is no way comparable to the exanthemata f certain severe pyrexias. It is, besides, exceptional or the evidence of contagion to be present at the me of the crisis in acute articular rheumatism; acute rticular attacks are never observed to arise from an bvious source of infection in the same family.

In fact, if one keeps to the usual methods, the ifectivity of acute articular rheumatism is not ident. But that of tuberculosis is no more obvious only direct contagion is considered. The infectivity f tuberculosis could not be proved until the tuberulosis attacks of adolescence and adult life were cognised as a lighting up of an infection caught uring infancy when family contagion could be clearly emonstrated. The fact that obscures the rheumatic roblem from an ætiological and a general point of iew is the excessive emphasis on the articular manistations, though these as we shall see in the sequel ly constitute an episode in the course of the disease.

No one thinks of tuberculosis pleurisy as being infectious; the tuberculosis is the condition which is infectious. A similar difficulty arises when the infectivity of cerebro-spinal meningitis is considered; only rarely does the infection spread from one case of meningitis to another; but it becomes evident when the initial rhinopharyngitis is considered and when the rôle of germ-carriers in dissemination of the disease is recognised.

It is not certain that definite infectivity is associated with the acute stage of the rheumatic disease. In a hospital ward, patients occupying beds next to a rheumatic patient are never observed to become rheumatic; but it may well be asked whether this infectiousness is not less direct and earlier, whether it is not present some time before the paroxysmal crisis which constitutes the attack of acute articular rheumatism.

The Rheumatic Disease, a Chronic Cardiac Disease with Successive Attacks Affecting the Serous System.

Even those authors who acknowledge the importance of the cardiac lesions which occur during the course of rheumatism, tend to regard them as secondary and to consider acute articular rheumatism, Bouillaud's disease, as primarily a polyarthritis, a disease of the joints. Pediatricians have been struck with the frequency of definite joint lesions during childhood, and the importance of the cardiac lesions. It seems to us that the general point of view in regard to rheumatism should be completely changed, and that we should not consider the disease as consisting of a series of acute lesions, first articular and later cardiac, but rather as a true chronic disease, similar to tuberculosis, syphilis, or malaria, particularly the first of these diseases.

The chronic disease, tuberculosis, may rémain almost entirely latent for many years, developing slowly and only becoming evident at certain times by acute attacks, such as an acute attack of pleurisy which may subside or heal. Thus it happens that caught in infancy and generally in the family surroundings, the signs of the disease often remain unrecognised until the time when the disease is definitely revealed as phthisis. Similarly, the rheumatic disease, or Bouillaud's disease, seems to us to be a chronic disease. The articular lesions appear the most important only because of their painful nature, which prevents them from passing unnoticed. The endopericarditis is really much more important, and this after a period of development readily becomes obscured again until a definite cardiopathy is established which leads to cardiac irregularity.

We think that in Bouillaud's disease the reservoir of the rheumatic virus is the heart, the endocardium, the pericardium, and particularly the myocardium. The acute attacks are distinguished either by a recrudescence of the cardiac lesion or by fresh articular symptoms. This method of interpreting the fundamental part played by the heart is the only way of explaining the development of the disease, which frequently after a stage during which articular and cardiac signs are present simultaneously, progresses with cardiac signs only, becoming more and more severe. The appearanee of these cardiac signs, accompanied by pyrexia (inflammatory irregularity of Bard, febrile irregularity of Josue), shows clearly the infective nature of the condition, and that it is not purely mechanical as was at one time supposed. The simultaneous occurrence of some joint lesions during the course of these febrile cardiac attacks demonstrates beyond dispute in some cases their rheumatic nature.

The idea of progressive cardiac rheumatism, introduced during recent years into pathology by Ribierre and his pupil Pichon, takes full account of the importance of rheumatic heart disease, which, far from being a complication as formerly believed, is really the most important part of the disease. The pathological anatomy shows well to what type of affection rheumatism belongs. Though in the joints the lesions appear to be congestive, inflammatory, and transitory, so that the disease resembles the acute inflammations, a study of rheumatic endo-

pericarditis shows that the pathological process really differs from these acute lesions, and rather resembles the subacute inflammations with a tendency to chronicity, such as are induced by the higher organisms, for instance, the parasite of tuberculosis or that of syphilis.

Scarring, not Ulceration.

The fact that the main ætiological factor in acute articular rheumatism does not produce vegetations and ulceration like the gonococcus or the pyogenic organisms, but warty nodules, scarring, and stenoses instead, shows its relationship to tuberculosis and syphilis, both diseases characterised by scarring and fibrosis. Is not the resemblance between rheumatic and tuberculous cardiac disease striking? The state of myocardium shows that it is probably the most important lodging-place of the rheumatic virus. Clinical experience reveals more and more the part played by the myocardium in rheumatic carditis. We have helped to emphasise the great clinical importance of these facts, which are, moreover, nowadays generally recognised by the Paris medical faculty.

In addition, the pathological histology shows, as we have seen with Prof. Letulle, a special type of reaction to which Aschoff's work has drawn attention adjoining the sclerotic myocarditis. We have with Prof. Letulle taken account of these interesting Aschoff's nodules, but we found it difficult to make of them true infective nodules comparable to tuberculosis; they represent rather inflammatory nodules with separation of muscle cells which ultimately come to resemble giant cells. Subacute nodular rheumatic myocarditis appears to us to be a specific lesion. In the whole organism, Aschoff's nodules symbolise defective defence on the part of the connective-vascular tissues against attack by the rheumatic virus. In the thickness of the myocardium this nodular inflammation is completed, or rather complicated, by a giant-cell proliferation of the striated muscle cells (muscular giant-cells) following the separation of the myoblastic elements. Atrophic disintegration of all the constituent elements of the myocardium is a later stage in the development of the myocarditis nodule. Finally, the last stage of all these inflammatory changes is represented by scarring (first soft, later hard).

The fibrous strands which thus ultimately separate the myocardial bundles appear to form a particularly favourable site for fresh nodular foci. One might say that the "rheumatogenous" organisms have a particular affinity for cicatricial (fibrous) tissue. The same predilection is shown for the depth of the thickened epicardium and for the fibrous pericardial adhesions. Possibly the same applies to the deeper parts of the thickened scarred endocardium and rheumatic valvular lesions. The presence of numerous acute and subacute nodular foci of different ages in the midst of sclerotic patches in the heart requires an explanation considering its great frequency. It is not sufficient to say that the rheumatic virus prefers the middle of inflammatory cicatrices; one must suppose that it lodges there, and that the repeated exacerbations originate here whatever the interval between them.

Infective Forms of Acute Articular Rheumatism.

Though in the classical types of this rheumatic disease the pyrexia and general symptoms accord with the severity of the joint lesions and the diagnosis is consequently easy, this is not always the case. In certain types which we have studied, joint symptoms are absent or slight, and a temperature approaching 40° C. (=104° F.), headache, severe general symptoms, general malaise, agitation, delirium, torpor make one think of typhoid or a generalised septicæmia, or if signs of endocarditis are present of an infective endocarditis. If there are, on the other hand, pulmonary or pleuro-pulmonary signs, as we have many times observed, one thinks, in view of the severity of the symptoms, of pneumonia; these phenomena are, however, related to the rheumatic disease, and subside with its specific treatment. In all these cases the knowledge of an attack of acute articular rheumatism in the past, or the occurrence, often late, of a few, scattered joint signs, makes on think of rheumatic disease and administer appropriat treatment.

The knowledge of the existence of infective form of this rheumatic disease should be generally recog nised. The physician should know that, beside th classical form in which joint symptoms predominat there are progressive cardiac forms in which the hear affection dominates the picture. There are form which are essentially infective in appearance in whic the signs of generalised infection prevail, and in whic the arthropathy is apparently accessory and ofte of late occurrence.

The Blood in Acute Articular Rheumatism.

The general view since the time of Garrod, Malasse and Hayem has been that acute articular rheumatisi is a disease which produces a diminution in th number of red blood corpuscles. Nevertheless, seems to us that however important the diminutio in red cells may often be in rheumatic patients, th pallor, which is so obvious in these patients, is n always due to this cause. These patients are mo often pale "ochro-dermic" subjects rather tha anæmic in the true etymological sense of the wor We have proved by our examinations that an obviou diminution of red corpuscles is often absent durir the acute stage in these rheumatic patients.

With regard to the white cell count there is oft at the time of the acute attack some leucocytos which is generally associated with an increase in th percentage of the polynuclear elements. In th uncomplicated cases of average severity the whi cell count is generally 13,000 to 16,000 per centimetr and the percentage of polynuclear neutrophils 75–8 In the milder forms the polynuclear increa is absent, and only a slight leucocytosis is observe This leucocytosis is absent, however, in those cas which are not accompanied by inflammatory reactio Entire disappearance of polynuclear eosinophils not observed during the acute attacks of rheumat disease, except possibly in the very early stages. Th rheumatic leucocytosis and polynucleosis do n continue as long as the acute phase of the attack they disappear when the inflammatory sympton of which they are but a sign subside. The transie mononucleosis may be equally important since th number of mononuclear cells may amount to 50– per cent. of the total white cell count.

We have, besides, asked ourselves whether the o ideas of the acidity of the blood in acute articular rhe matism conforms to the modern conception of ion acidity expressed in terms of pH and alkali reserve.

In rheumatic cases we have never been able detect the least disturbance which might point to a alteration in the reaction of the humoral mediu We have investigated the problem by numero methods, by estimating the pH and the alkali reser of the blood and the pH of the urine, the amount phosphoric acid in the urine, and by other metho The blood pH and the alkali reserve are normal rheumatic patients. In these the ionic acidity the urine also remains normal.

On the other hand, the amount of fibrin in t blood is increased in acute articular rheumatisi In fact, in patients with rheumatism or pneumon we have found the highest values of fibrin in t blood. In pneumonia values of 10 or 12 g. of fibr or more per litre of plasma may be recorded (in patient with serous para-pneumonic pleurisy, whi rapidly become purulent, we have observed as mu as 16 g. per litre of plasma); in acute articul rheumatism the value frequently reaches and excee 10 g. per litre. But the increase in fibrin in the blo is of no value for the differential diagnosis of articul lesions. Though rheumatic hyperfibrinosis is of diagnostic significance it has some prognostic valu It is, in fact, proportional to the severity of the acu joint lesions. In the obviously inflammatory cases it m reach 9, 10, or 12 g., in the milder forms it does n exceed 6·76, 5·22, and 4·20 g. The more severe the acu joint lesions, the higher the fibrin content of the bloc

If the development of the hyperfibrinosis is followed a number of patients, as we have done, one finds at far from disappearing under the influences of icylate treatment at the same time as the pyrexia d the painful symptoms, it continues for a long ne after the joint symptoms have subsided. When e temperature has returned to normal and the ins have entirely disappeared, when the administion of salicylates in reduced doses is continued as imple precautionary measure, some hyperfibrinosis nains as evidence that the inflammatory process ll persists. As long as the fibrin value of the blood s not returned to normal or subnormal it is advisable continue the administration of salicylates.

Treatment of Acute Articular Rheumatism.

Our conception of acute articular rheumatism is t merely of academic interest; it readily suggests as of prophylaxis, analogous to those of tuberosis, which would deprecate the association in the nily of young children and patients suffering from ute attacks; this is as yet purely hypothetical. t it follows from our conception that treatment rheumatism should be continued for some time er acute attacks have subsided by rest and the ministration of salicylates; some clinicians even vocate treatment between the attacks with small ses or medium-sized doses of sodium salicylate. We not insist too strongly on the importance of the se from this point of view, and the value of using intravenous route in resistant cases, combining a xture of sodium salicylate and glucose and using ficiently dilute solutions.

We generally use a mixture in which 5 per cent. sodium salicylate is dissolved in a 10 per cent. ution of glucose. The effect of sodium salicylate the development of rheumatic endocarditis is l under discussion. Has the drug which is so ective in the articular attack the same effect in the ute cardiac attack? This is a question on which is difficult to form a definite opinion, and it still nains in the region of hypothesis.

Finally, the idea of the chronicity of Bouillaud's ease (acute articular rheumatism) gives us a ans of explaining the beneficial effects of certain rmal waters which appear to help to relieve some gering joint symptoms, and to mitigate some types progressive and prolonged cardiac rheumatism. In nce some indeterminate and radio-active waters, h as Bourbon-Lancy, Plombières, and Neris, pear to have a beneficial effect on persistent umatic attacks; in the acute forms of articular umatism they should be avoided, as should alkaline ters and muds; these have a place on the other nd in the treatment of the other kinds of joint on, which, we emphasise in conclusion, have hing in common with acute articular rheumatism ept the term "rheumatic."

THE INFLUENCE OF ENVIRONMENT ON RHEUMATIC INFECTION IN CHILDHOOD.*

REGINALD MILLER, M.D., F.R.C.P. LOND.,
PHYSICIAN TO PADDINGTON GREEN CHILDREN'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS AND LECTURER IN CHILDREN'S DISEASES, ST. MARY'S HOSPITAL, LONDON.

AMONG the present-day problems of juvenile umatism there is, in my opinion, none worthier our accurate study than that of the influence of vironment on the large scale production of the ease. My reason for insisting on the pre-eminence this particular question is that, as the position pears to-day, in our efforts to prevent and control disease in this country, we have a better chance success by getting to work on environmental uences than by any other means. With whatever readiness public and private funds may be forthcoming for the relief of the child-victims of rheumatism, it is its prevention which demands our hardest thought and greatest effort.

My subject naturally divides itself under two chief headings: first, the evidence that environment is an important predisposing cause of juvenile rheumatism; secondly, the nature of the environmental factors at work.

Before I pass on to these two questions I want to spend a moment in considering with some precision what it is that we have in mind when we speak of a disease as being "produced by" some fault of environment. Clearly, in the case of an infective disease, we cannot regard environment as the "cause" in any strict sense; but we may think of it as leading to increased virulence in the bacterial agent, to a diminished resistance in the patient, or to the development of some abnormal condition which, in its turn, acts as a preliminary to the infection in question. Thus, in the case of juvenile rheumatism, environment might act by increasing the activity or dosage of the infecting micro-organism, or by diminishing the child's resistance to the rheumatic infection, while it might also play an important rôle in the production of the disease, were it to predispose towards the occurrence or persistence of tonsillar infection.

But for myself I do not doubt that environment also works more frequently and more powerfully in another way—namely, not so much towards originating the infection as by stimulating and unmasking an infection already latent, turning it from a mild to a severe attack. Now if this is so in the case of juvenile rheumatism, obviously it is of great importance, for it means that environment is specially concerned in the production of rheumatic heart disease.

There is one further preliminary point to be considered. In thinking out the ways in which environment may be conceived to predispose towards an infection, it is difficult to get away from the idea of its influence being at work on some micro-organism external to the patient, lurking ready to attack and infect him. But what if the modern conception of the bacteriology of rheumatic infection is correct, that the infecting agent is a constant inhabitant of the human alimentary tract which becomes exalted in virulence, assumes a pathogenic rôle, and so produces the disease? In such a case we must be prepared to find that environment plays a part different in detail from what we are accustomed to observe.

Juvenile Rheumatism an Environmental Disease.

The first question which I have to discuss is this: Is there evidence that environment plays an important part in the production of juvenile rheumatism?

Considered as a widespread endemic disease of this country, juvenile rheumatism shows one outstanding feature—namely, that it is massed amongst the children of the poor, and practically absent from the children of the well-to-do. I need not to-day produce figures to prove the truth of this statement, which is, I think, universally accepted. We need no better proof of it than the fact that the ordinary educated layman has still no idea that rheumatism is a common, or indeed possible, disease of children. He is quite unfamiliar with it in the families of his friends and relatives.

This class incidence is so clear that it is evident that we cannot hope to understand the large scale production of the disease until we know the explanation of it. Prominent among the possible explanations comes, of course, the influence of environment. Have we any direct evidence that this is the correct explanation? We have one very strong and simple piece of evidence: I allude to the investigation published in the Medical Research Council's Report into the incidence of rheumatism in poor-law residential schools. Four schools, housing about 1800 children, who all came from the poorer classes, were examined over a number of years. Left in their own homes it is impossible not to suppose that dozens

* Communicated to the Bath Conference on Rheumatic Diseases.

of instances of rheumatism would have arisen amongst them; yet transferred to the residential schools they remain practically free of the infection. On this single piece of evidence alone we may confidently base the opinion that juvenile rheumatism is essentially an environmental disease. There are, of course, many other confirmatory proofs of this view.

There are other possible explanations of the freedom from rheumatism enjoyed by the children of the richer classes, such as contagion, heredity, and diathesis. Heredity and diathesis are hardly within my subject, so that I will only say that the evidence just quoted from the residential poor-law schools makes it quite clear that they cannot be factors of great moment. Contagion falls within the scope of environment, and I must digress to consider it.

Contagion.—The question, then, can be put thus: How far is the mass production of rheumatism amongst the children of the poor due to case-to-case infection?

We may be confident that in the healthy surroundings of a hospital ward rheumatic infection does not spread from one child to another; can we be equally sure that in the unhealthy homes of the poor this does not occur? I think we can. The theory of contagion has no sort of supporting tradition behind it among clinical workers at rheumatic problems. The investigations of the Medical Research Council's Report were specially undertaken with a view of testing this theory, but no evidence in its favour could be found. Further, spread by contagion could not explain the class incidence of the disease when that is considered accurately, as we shall see later; and it is not in agreement with the modern bacteriological conception of rheumatic infection. If this last is true we must liken rheumatism to such infections as lobar pneumonia and appendicitis rather than to diseases due to imported organisms such as tuberculosis. Now everyone has seen cases of pneumonia or appendicitis arise in more than one member of a family synchronously or close together, but does anyone think that contagion accounts for the thousands of cases of these diseases which occur?

The theory that juvenile rheumatism spreads by case-to-case infection has its most doughty champion in A. C. F. Halford, of Brisbane, and we cannot deny that where an infective disease is common and is massed in one section of the community, many of its ætiological factors will appear consistent with a possible contagious spread; but to allow that such a method of infection accounts for the huge numbers of rheumatic cases which we find in this country would, I am sure, be absolutely wrong. Were contagion at the botton of it all I am convinced that we should have known it long ago.

Conclusion.—To sum up, therefore, the general question of the influence of environment on juvenile rheumatism, we may regard this influence as so powerful that it is fair to regard the rheumatism of childhood as an environmental disease. In saying this I think I am supported by the general trend of medical opinion in England.

The Environmental Factors in Juvenile Rheumatic Infection.

I pass now to discuss the nature of the various environmental factors which aid and abet the production of juvenile rheumatism. As a preliminary I should like to suggest that so close is the association between juvenile rheumatism and tonsillar disease, that it seems as though the environmental factors at work must, to some extent, centre round the production of diseased, infected tonsils; and in saying this I have not at all in mind the too familiar child with enlarged tonsils and adenoids: I do not fear contradiction when I say that this is not the type which provides the bulk of rheumatic children. And here I may digress to say that in my view one of the reasons of the immunity to rheumatism found amongst rich children is the present-day practice of early and complete removal of diseased tonsils. When we remember that 70 per cent. of the boys now joining Eton College have already had their tons removed (W. Attlee), we see that the numbers a large enough to make a difference between the ri and the poor.

Climatic and Seasonal Influences.—Passing ov many interesting points in connexion with t climatic and seasonal incidence influences on t production of juvenile rheumatism, I will conte myself with saying that the world distribution the disease and its seasonal incidence in this count both suggest strongly that a combination of dar and cold predisposes to it.

Poverty.—I come now to the all-important influen of poverty. It is clear that were there no pover there would be practically no rheumatism proble in children; but the question arises: Is the massi of juvenile rheumatism amongst the poor due their poverty per se or to some other factor, concomitant of poverty?

I have already spoken of the remarkable freed from the disease enjoyed by the children of t rich. The rheumatic stratum of society has, therefo an upper limit, and consideration of the incidence heart disease in secondary schools suggests that t limit runs at, or perhaps a little above, the gra attending the State elementary schools.

Yet it is probably not correct to regard juven rheumatism as a "poverty disease," for there evidence that its frequency does not increase as t lower depths are reached. This was pointed out F. S. Langmead as long ago as 1910, and has be repeatedly confirmed by nearly all who ha investigated the matter. A. P. Thomson, who l made a very long and careful inquiry into this po in Birmingham, finds the same fact, and further th the rheumatism map of that city does not accurat correspond with the poverty map. The same cl incidence has been found by V. Coates and R. Thomas in Bath, by J. Morrison in Bristol, by R. Vercoe in Chelmsford, and by myself in West Lond Particularly clear on this point was the verdict the Medical Research Council, and the wording of it worth quoting: "If hospital patients are divided i three classes according to the degree of poverty, t poorest of these three, the very poor and destitu show a lower incidence of rheumatism than t other two."

In the same way the concomitants of deep pover such as underfeeding, overcrowding, excessive d defective sanitation, have not been found to play conspicuous part in predisposing to this disea and if the infection is not contagious and is not c to a germ imported into the patient from outsi there seems no particular reason why they should do

I must not be interpreted as saying that juver rheumatism is rare in the poorest, for this is qu untrue; nevertheless we seem to be faced with t peculiar fact, that although the disease is so stric confined to the poorer classes, it hits particularly t upper poor, families of policemen, postmen, railwaym and decent artisans. I am told that no other disea except dental caries, shows quite the same cl incidence as this.

To sum up this matter: we must conclude th although poverty is a predisposing cause of imme importance, it is not merely poverty per se which at work; some other factor, a common concomit of poverty, must also be at work.

Urbanisation and Industrialisation.—We are fai sure that juvenile rheumatism is a disease of tow rather than of rural areas, and of industrial tow rather than of residential towns. We are wait for fuller and more reliable figures from rural distri to confirm this, and we hope that these will e forthcoming from the "field investigation" in th western counties inaugurated lately by Dr. Ca Coombs.

School Environment.—When we remember th juvenile rheumatism can be regarded as essenti a disease of the elementary school child, wher richer children remain unaffected, we may natura imagine that the mere attendance at an elementa

hool has a deleterious effect in predisposing towards ie infection. Comparing the circumstances of the ch and the poor child attending a day school there re several differences that militate against the poor ild: compulsory attendance, the system of lucation grants per attendance, lack of protection gainst exposure to cold and wet weather, lack of anging and drying facilities if arriving wet at hool; all these things militate against the poorer ild, especially against the delicate child, and most all against the rheumatic child. We cannot, erefore, but conclude that in such circumstances ie rheumatic child must be apt to do badly and to quire heart disease, just as the strain of school ork, especially of a competitive sort, is apt to ring on chorea in an infected subject; yet in the tual origination of the disease the home environment lays, in my opinion, a much larger part than does ie school environment.

Diet and Nutrition.—That diet and general nutrition ting through intestinal indigestion and debility ay play a part in the production of juvenile eumatism has occurred to many minds, particularly, rhaps, in connexion with the abstruse subject of ie determination of relapses and recrudescences. have myself failed to reach any conclusions on these atters. Dr. C. W. Vining has particularly studied ese aspects of the problem, and we are to have the portunity of hearing his views later in this nference.

Damp Dwellings.—I come last to a subject which believe to be of great importance—namely, the fluence which residence in damp dwellings exerts n the production and unmasking of juvenile eumatism. Some affect to regard this as a mere ogy; others think that it works merely by a wering of resistance, and has no particular relation-ip to rheumatic infection. For my part I regard amp as the great ally of poverty in producing eumatism and heart disease in children. In this atter I have in mind damp associated with cold.

Evidence associating damp dwellings with a heavy cidence of juvenile rheumatism is accumulating. he world distribution and the seasonal incidence in ngland are such that it seems hardly possible that amp and cold should be of no moment in predisposing wards the infection. Further, we can easily see at they might do so through their tendency to ve rise to catarrhs and tonsillitis. Again, it is a ggestive point that clinicians note that in damp rroundings rheumatism tends to run an intractable urse, leading to severe heart disease. F. J. Poynton, ur great pioneer in all matters concerned with ute rheumatism, has taught this for many years.

When we come to the distribution of juvenile eumatism in towns it is found that it tends to llow watercourses, to increase in low-lying areas, nd although the "rheumatic map" corresponds oughly to the "poverty map" there are deviations om it to be accounted for by these tendencies. In addington, for instance, we get most of the rheumatic ses not from the poorest streets, but from those ose to the canal and submerged rivers. I have already entioned A. P. Thomson's rheumatism map of irmingham.

In the investigations undertaken for the first port of the British Medical Association's Committee f Inquiry on Rheumatic Heart Disease in Children, ie housing of rheumatic children was examined in ath, Bristol, and West London, and it was found at in 62 per cent. of the instances the children were ving, when first showing symptoms of the infection, damp houses. In Paddington, in a new series of ver 200 cases, I have found much the same proportion, hereas taking non-rheumatic families the proportion ving in damp houses is only about half as large. Ve also find that the middle floors of the houses, hich are, as a rule, the driest floors, provide the west number of cases.

Such facts as these suggest that damp dwellings ave a connexion with the development of juvenile heumatism, and that this connexion is something real and particular to this disease. It may be asked if stress is to be laid on the site of the house or the state of the house itself. Of course, where the site is damp, damp houses are likely to be common, and I am persuaded that there are building sites on which no cheap houses can ever hope to remain dry; but I think the condition of the house is of more importance than that of the site, that it is safer to live in a dry house on a damp site than in a damp house on a dry site. One piece of evidence may be quoted. Although in Eton Town there is, I am told, plenty of juvenile rheumatism, in Eton College, Beaumont College, and the Imperial Service College, all lying in the same district and accommodating between them some 1600 to 1700 boys, the disease is practically unknown.

When I was dealing with the association of poverty and juvenile rheumatism, I said that poverty acting alone and of itself would not account for the mass production of the disease—that some other factor, some common concomitant of poverty, was also at work. This factor I believe to be that of residence in damp dwellings. This governs to some extent the distribution of the disease within the rheumatic stratum of society, and determines in many cases why one family suffers and another of the same grade of poverty escapes.

To this view the objection may be made that if damp has this effect the poorest would suffer most, as they are likely to live in the dampest houses. To this I would submit the following answers: (1) The immunity to rheumatism in the poorest is only relative; no one thinks that in them the disease is rare, on the contrary it is quite common. But the point is that if all the attributes of poverty acted together, rheumatism would be more common and not less common in the poorest than in the stratum above them; whereas, if one of the attributes acts out of proportion to the others this sequence will not necessarily be found. (2) The slum child does not necessarily live in a damp room; on the contrary, many slum houses are well-built old houses, which, though most dilapidated, remain weatherproof. In my view where a slum dwelling is damp the incidence of rheumatism will tend to be heavy; where it is dry it will tend to be lighter. (3) Overcrowding, which is notably absent in rheumatic cases, by promoting warmth may tend to prevent damp. However undesirable it may be from other aspects, it may well be that for many to live together in one room used as a kitchen, may give some protection against this particular disease.

Conclusions.

1. Environment, taken as a whole, is of such importance in the production of juvenile rheumatism that the disease may be regarded as an environmental disease. To alter the environment of children is sufficient to prevent the appearance of the infection amongst them.

2. General lowering of resistance is produced by such factors as poverty, urbanisation, and industrialisation; the tendency specially towards rheumatic infection is largely determined by living in damp rooms, exposure to wettings, chills, catarrhs, &c.

3. Of the environmental factors at work the two of chief importance are poverty and damp houses.

PAYING PATIENTS AT MANCHESTER EYE HOSPITAL. The annual report states that the nine beds (out of 148) which were experimentally set aside for paying patients have been constantly occupied. Last year there were 2579 in-patients and 32,346 out-patients. Another experiment, begun last year, brings to the institution 10*s.* 6*d.* per week for an in-patient and 2*s.* 6*d.* for an out-patient who is a member of the Hospital Saturday Fund.

VENTNOR HOSPITAL FOR CONSUMPTION.—At the annual meeting of the governors of the Royal National Hospital for Consumption at Ventnor it was stated that it was designed to build a modern sanatorium for the use of ultra-violet rays, and for the more intensive application of heliotherapy to tuberculosis in bones and joints, but that the cost would be £50,000. Although one-half of the patients are from London the geographical limitations of King Edward's Fund do not permit of help from that source.

CICATRICIAL STENOSIS OF THE ŒSOPHAGUS.*

BY LINDLEY SEWELL, M.B., B.S. LOND., M.R.C.S. ENG.,

HON. AURIST AND LARYNGOLOGIST TO THE MANCHESTER ROYAL INFIRMARY; LECTURER IN OTOLOGY TO THE UNIVERSITY OF MANCHESTER.

Cicatricial stenosis of the œsophagus is much less common in this country than in America and on the continent, probably because solutions of lye, which consist mostly of caustic soda, are there in general use for household purposes and are drunk in mistake for water, coffee, or wine. The caustic burns which follow lye-drinking are the commonest cause of stenosis of the œsophagus; N. Zimmony states that out of all cases admitted into the throat departments of the hospitals of Berlin and Budapest during the last three years, 10 per cent. had œsophageal stenosis from this cause. J. Guisez, of Paris, analysing 2500 cases of diseases of the œsophagus, examined with the œsophagoscope, found cicatricial stenosis in 185 cases, or 1 in 12; all except 1 per cent. were due to swallowing caustic. Other causes are burns from swallowing nitric, sulphuric, or other acids, bichloride of mercury, or ammonia. The infective fevers, such as scarlet, diphtheria, and typhoid, also syphilis and tuberculosis, sometimes produce ulcers in the œsophagus which may cause stenosis on healing. Chevalier Jackson states that peptic ulcer of the œsophagus is also a cause, and considers that a spasmodic stenosis, with its consequent œsophagitis and erosions and later (pyogenic) infection, may occasionally bring about cicatricial narrowing. The prolonged retention of a foreign body may, when it gives rise to surrounding ulceration, cause stenosis, as also may unskilled attempts at removal of foreign bodies. Stenosis may also result from gunshot and other wounds or burns from hot food or drink. Gottstein reports a case caused by swallowing a hot potato. Gabriel Tucker states that the majority of cases admitted to the Bronchoscopic Clinic, Philadelphia, are children whose stenosis is usually due to swallowing lye.

A single stricture is rare and generally congenital. Usually there are two or more strictures which rarely involve the complete circumference of the œsophagus. Successful treatment depends on this fact, for although the scar tissue is inelastic, the remaining segment of normal œsophageal tissue can stand stretching, and so dilatation is possible.

According to Jackson, the commonest sites of stricture are at the points of normal narrowing of the tube—namely: (1) at the level of the left bronchus; (2) at the level of the crico-pharyngeus muscle or the circular fibres of the inferior constrictor of the pharynx; (3) at the hiatus level (diaphragmatic).

On examination with the œsophagoscope the gullet is often found to be dilated above the stricture, and if the stenosis is of some duration a certain amount of œsophagitis may be present, with erosions of the mucous membrane. The scar is usually pale or white and may be level with the surrounding mucosa or depressed, or may show as a hard ridge. In some cases there is marked stagnation of food and secretion above the stenosis, and these must be washed out before a proper examination can be made.

Symptoms.

The immediate effect of swallowing a caustic is a severe acute œsophagitis, with difficult and painful swallowing and some fever. These symptoms usually pass off in a fortnight or less, and swallowing may become almost normal for a time. Then, as contraction gradually develops, the patient experiences an increasing difficulty in swallowing, first solids, then liquids, and finally, in severe cases, even saliva. Loss of weight is progressive and may become very marked. In the earlier stages the symptoms may be intermittent and may closely simulate a spasmodic stenosis; this is due to temporary blocking with a large bolus of food. Occasionally contraction only occurs very slowly and the patient may first suffer from it many years after swallowing the caustic.

Diagnosis.

The history of having swallowed a caustic or of one of the other ætiological factors already enumerated will, of course, make a diagnosis of cicatricial stenosis very probable. Certain conditions must, however, be excluded. These are cancerous growth of the gullet, foreign body, spasmodic stenosis, diverticulum, and the various forms of compression stenosis such as aneurysm, malignant growths of intrathoracic viscera, and goitre. The first step is X ray examination with an opaque mixture which will usually give great help. Then an examination with the œsophagoscope should be made. A spasmodic stenosis will yield to gentle and continuous pressure with the tube, or, if the examination is made under complete general anæsthesia, will not be encountered. Cancer will reveal itself as a fungating area, bleeding readily, or as a resistant infiltration of the wall of the gullet. Compression stenosis is characterised by a sudden change of the full lumen to a linear or curved slit, and the compressing mass is sometimes felt by the œsophagoscope and the radiogram may show the cause.

Prognosis.

Formerly, when blind bouginage was the routine treatment, the outlook was bad, as in many cases the œsophageal wall was sooner or later perforated. Some pressure is necessary to dilate and traverse a stricture, and the bougie may be engaged in the bottom of a pocket and forced through the wall.

Under modern methods the prognosis is good; the earlier a case comes under observation the better the outlook and the shorter the treatment.

Treatment.

It would serve no useful purpose to describe the many methods of treatment which have been tried. Blind bouginage may be mentioned only to be condemned by the oft-quoted dictum of Trousseau: "Sooner or later all cases of stricture of the œsophagus die of the bougie."

There are two main lines of approach to the stricture: (1) Through the mouth; (2) from below after a gastrostomy.

The passage of graduated bougies under direct vision with the œsophagoscope is favoured by Chevalier Jackson. The size of the bougie is increased very slowly and it is passed at intervals of four to seven days. Multiple strictures are dilated in order from above. P. P. Vinson, of the Mayo Clinic, and H. S. Plummer, among others, have induced the patient to swallow a string, and then threaded on to end of this through an eyed bougie. The string is pulled taut and the bougie pushed and guided through the stricture on the string. Many successful cases are reported as the result of treatment by this method. Loretta and Mickerliez introduced rubber-coppe forceps upwards into the stricture from the stomac and forcibly dilated it. Some successes were reported but the mortality was high. One difficulty was i finding the hiatus of the œsophagus or cardia. Billrot passed from the stomach a filiform bougie to which string was attached and, fixing the string on to conical-shaped bougie, was able to pull it through th stricture. Ochsner and Guisez have both passe strings from below and pulled through a single an a doubled rubber tube respectively.

The Gabriel Tucker Method.

I have recently employed this method in thre cases. The first essential step is a gastrostomy, whic by freeing the œsophagus from the irritation c retained food and consequent œsophagitis, wi usually soon cause the lumen to enlarge sufficientl to allow the swallowing of a silk thread. The nex

* A paper read at a meeting of the Manchester Surgical Society, Dec. 8th, 1927.

ge is to induce the patient to swallow a string of . 15 button-hole twist silk which can usually be luced to pass with a draught of water; in one case e first few inches were coated with chocolate. casionally Tucker found it necessary to attach a it shot to the end of the silk. For small children myself have not treated any) the silk is passed ough the nose on a soft rubber catheter into the sopharynx, and then introduced, a little at a time, m the anterior nares. Considerable time and tience may be needed, but the silk will be swallowed entually. The distal portion has then to be found the stomach and brought out through the gastros- ny wound; this is done with a blunt hook or blunt asil pillar-retractor, and may take considerable ning. A length of No. 4 twisted silk is now ached and pulled through from stomach to mouth, d the two ends tied together. The bougies are made rubber, moulded on to braided silk thread. A loop left free at each end, and the intervening silk is otted to prevent the rubber pulling out. The ends the bougie are tapered and are graduated, like heters, from 10 to 30, French scale. The length each bougie is 35 cm., and this is long enough to gage all the stenosed areas simultaneously. The silk cut and the lower end attached to one end of the ugie, to the other end of which a new piece of silk ied. The upper length of silk is pulled, and a finger passed to the back of the tongue and the thread ered over it. The bougie is pulled up very gently o the stricture, where it is allowed to remain for lf an hour; it is then withdrawn through the uth, bringing with it a fresh length of silk, the two ds of which are tied together and left. My patients eferred the silk through the mouth, but in children must be brought through the nose, otherwise they ll bite it through. The bougie is passed once weekly, d a larger size is not passed until the one in use sses quite freely. No anæsthetic is used, there is discomfort, and the patient does not remain in spital.

Although the gastrostomy feeding-tube remains in u, food is very soon taken by the mouth. Jackson ates that a lumen of 7 mm. is sufficient for all usual rposes. We have found that roast beef is the last ing to resist swallowing.

CASE 1.—A chemical student, aged 20, was admitted into e Manchester Royal Infirmary under Dr. Craven Moore th the history of having swallowed some caustic soda en using a pipette five weeks previously. She suffered erely from dysphagia and vomiting and could only allow fluid in small sips. Her weight was 5 st. 8 lb. e X ray report from Dr. A. E. Barclay stated: "Conical icture—smooth—lower third complete—œsophagus irri- ble, showing well-marked peristaltic and retroperistaltic ves." The case was referred to me for examination with e œsophagoscope, and I reported "Non-malignant organic icture 11½ in. from the teeth" and ventured to suggest immediate gastrostomy and later the use of bougies. Mr. H. Burgess performed the gastrostomy and suggested at I should try Plummer's method. It was finally decided, wever, to use the Tucker method, and this has been carried t as described, treatment lasting about a year. The tient now weighs 8 st. 12 lb. and can eat any food, d no bougie has been passed for three months; the silk read is discarded but the gastrostomy has been kept open case of any further need of bouginage. (A year has apsed, the gastrostomy wound is closed, and the patient n swallow any kind of food. She carries out her full duties a school teacher.)

CASE 2.—Male aged 47. Swallowing became slightly fficult in 1914, and the difficulty gradually increased until 21, when only fluids could be passed. The cause was the cidental taking of a nitric acid preparation used in an gineering works for cleaning metal. Lived on liquid food til operation and retrograde bouginage in August, 1926. ougie passed once weekly, the large size being reached by ovember the same year. Solid foods of all kinds now ken when carefully chewed. Weight increased from st. 5 lb. to 8 st. 4 lb. X ray photograph showed irregular ear stricture about one inch above the diaphragm.

CASE 3.—Male aged 55. Had difficulty in swallowing for months; cause uncertain, but probably the swallowing a corrosive. Has had bougies passed under general æsthesia on three previous occasions. Admitted to the oyal Infirmary under my care, after a gastrostomy by Mr. Howson Ray the usual routine was followed. This case proved more difficult than the two previous ones, in that the bouginage had to be continued once weekly or relapse ensued. With regular treatment he is able to swallow all kinds of food, including roast beef.

In this paper I have drawn largely on the writings of Dr. Gabriel Tucker, of Philadelphia, who was also kind enough to give me personal instruction in the method.

A CASE OF

CONGENITAL MORBUS CORDIS

STUDIED OVER A PERIOD OF TWELVE YEARS.

BY FRANCIS BACH, B.M., B.CH. OXF.,

RESIDENT MEDICAL OFFICER, NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

THIS is the case of a man who was weakly, pale, and short of breath from early childhood, who at the age of 18 came under medical observation, and who, until his death last year at 30, was under regular medical supervision. A constant visitor to many of the London teaching hospitals and a frequent clinical case at medical examinations, he was brought finally to the London Temperance Hospital, where we had an opportunity of studying the case clinically and of a post-mortem examination.

On May 7th, 1927, the patient, aged 30, had a fainting attack in a neighbouring street and was brought by the police to the London Temperance Hospital.

Résumé of Past History.—He had been a seven months baby of an apparently healthy stock—a "blue baby"—under weight and weakly; as a child he was unable to run about like other children on account of shortness of breath and fatigue on the least exertion. He was kept at home and was sent to a special school. In 1915, at the age of 18, he first came under observation at St. Bartholomew's Hospital, where he was admitted for investigation as he had been rejected from the army on account of his heart. He complained of occasional pain round the heart and, for the three months prior to his examination, of a cough with a slightly blood-streaked sputum.

As a boy he was ill-nourished, cyanosed, somewhat underdeveloped, with bulbous fingers and toes and an infantile-shaped chest. His heart was not enlarged; the pulse-rate was regular at 80–90, the systolic blood pressure varied from 96–119 mm. Hg; a soft systolic murmur was heard to the left of the sternum, confined to the apical area. The spleen was not palpable, the stools were normal. The blood picture showed red blood corpuscles 8,300,000, Hb 150 per cent., C.I. 0·88, white cells, 7600. A radioscopic examination revealed no abnormality of the heart and some increased hilar opacity, but normal lung areas. The diagnosis of congenital morbus cordis was made; a note was added to the effect that no congenital defect other than a doubtful patent foramen ovale was found, and the patient was discharged as unfit for the army. He continued his normal restricted life.

Two years later, at the age of 20, he began to complain of giddiness and fainting attacks, associated with severe frontal headache, which appeared to be brought on by walking. Later he had occasional hæmoptyses. It was on account of these attacks that during the next ten years he was admitted to so many London hospitals.

In 1924 he was admitted unconscious to St. Bartholomew's, brought by the police. When seen in the surgery he was deepy cyanosed, unconscious, retching violentlyand vomiting small quantities of food. The breathing was slow and weak. The radial pulse was not palpable. Strophanthin, gr. 1/100, was given intravenously, the pulse improved rapidly, and was soon of good volume at a rate of 80 to the minute. The patient gradually regained consciousness. He was able to describe how he had suffered from attacks of giddiness as long as he could remember; that suddenly he would feel as if his head was going round, objects would look double, that to prevent himself from falling he would lean against the wall or grasp the railings during an attack. The seizure would last a few minutes and be followed by a severe headache, localised across the forehead and down the right side of the face; with this would be associated a severe stitch-like pain shooting from the left groin to the left nipple. The attacks had gradually become more severe and of longer duration; there would be loss of consciousness and he would feel unwell for two or three days afterwards.

In 1926, on account of severe hæmoptyses, he was admitted to University College Hospital. Investigation revealed no evidence of pulmonary tuberculosis, and sputa

examinations were repeatedly negative. On radiological examination there was much fibrosis of the lung roots, with a heart shadow slightly larger than normal. Electrocardiographic tracings revealed a normal rhythm with right-sided preponderance and an enlarged P wave in lead II.

Early in 1927 he was readmitted to St. Bartholomew's in another attack of unconsciousness, and the diagnosis of congenital defect was again made. The red cell count in the blood was 9,200,000 per c.mm., the oxygen capacity of the blood was 20·21 vol., and the arterial saturation 63 per cent.

Condition on Admission to the London Temperance Hospital.—He was brought in unconscious, collapsed, with a rapid pulse and subnormal temperature. On examination next morning (May 8th, 1927): Thin man, medium height, markedly cyanosed cherry-coloured lips. Eyes: Pupils small, equal, react to light and accommodation. Mouth: Tongue furred, mucous membranes cyanotic; teeth very septic, many missing. Neck: No abnormal pulsation, no glands palpable. Chest: Poorly covered, symmetrical except for slight precordial bulge. Lungs: Air-entry good; vesicular breathing; no added sounds. Heart: Apex-beat not seen, but felt in fifth left intercostal space, 4½ in. to the left of the midline; localised, not heaving. No thrill at apex or base. A.C.D. not enlarged. Blood pressure, 95/50. Radial pulse palpable; fair excursion; regular rate 120; heart sounds clear, but I and II at apex somewhat muffled; pulmonary second sound not accentuated. No bruits. Abdomen not distended; moves well. Spleen not palpable. Liver not palpable. Abdominal reflexes normal. Marked clubbing. Tendon reflexes all exaggerated; no signs of congestive failure. Urine: Faint trace of albumin; specific gravity, 1015. No sugar, blood, or acetone. Blood counts: R.B.C., 8,310,000; Hb, 90; C.I., 0·54. W.B.C., 8600 (immediately after venesection); polymorphonuclear, 48 per cent.; lymphocytes, 47 per cent.; large mononuclear, 3 per cent.; eosinophiles, 1 per cent.; basophiles, 1 per cent. Two weeks later: R.B.C., 928,000; Hb 92; W.B.C., 9600.

Ophthalmic Examination.—Conspicuous engorgement of retinal vessels both arteries and veins; the disc highly coloured. Otherwise normal. Sputa examinations for tubercle bacilli negative.

A diagnosis of congenital morbus cordis was made. The polycythæmia was thought to be essentially secondary to the congenital heart defect, but due in part to some focus of infection. A search for foci was made, and on May 13th six carious teeth were removed under general ethyl chloride anæsthesia.

On May 16th the patient complained of pain in the neck, which was relieved by fomentations. A throat swab showed a predominant staphylococcus and *Micrococcus catarrhalis*. On the 18th he complained of severe headache situated bilaterally in the frontal and temporal regions, and of a cold and running from the eyes. The mouth appeared clean. A careful examination of the central nervous system elicited no abnormal signs. A small venesection was performed. On the 24th a venesection of 200 c.cm. of blood relieved the headache. The temperature became raised, varying from 100°–103° F., pulse-rate 85–100. On the 26th the temperature remained raised the patient hiccoughed frequently; the discs appeared normal. All the tendon reflexes of the lower extremities were symmetrically exaggerated. On lumbar puncture 40 c.cm. of turbid fluid under greatly increased pressure were withdrawn and revealed many pus cells, the majority of which were polymorphonuclear, and a Gram-positive bacillus. The fluid was cultured on blood-agar; there was no growth. On the 27th the patient died.

Post-mortem Examination.

Cyanotic asthenic type; marked clubbing of the fingers; the mouth appeared clean and the tooth sockets healthy.

Chest: A few pleural adhesions, no free fluid. The lung substance somewhat œdematous, air-containing; no evidence of old scarring, calcareous glands, fibrotic or bronchiectatic changes. The trachea and bronchi appeared normal and the bronchial arteries slightly enlarged.

The heart did not appear enlarged—weight 12½ oz. The pericardium was normal. On examination of the external surface a single vessel appeared to arise from both ventricles; this proved to be the aorta. The right ventricle was enlarged, and the musculature was hypertrophied so that its wall equalled that of the left in thickness. In the substance of the upper part of the anterior wall of the right ventricle a separate cavity, measuring about 1½ in. by ½ in., was found. This proved to be the bulbus cordis, existing as a separate chamber, as normal fusion with the right ventricle had not taken place. This chamber was found to communicate with the right ventricle by a small aperture, through which a probe could just be passed. The tricuspid and mitral valves appeared to be normal. The foramen ovale was a comparatively wide slit-like orifice, and the interventricular foramen was the size of a shilling. The aorta arose from the right ventricle; the circumference of the first part was slightly greater than normal. The valves were normally formed a healthy. There was only one coronary artery, which arc from the normal position of the right coronary arte The intima of the aorta showed slightly early atheromatc changes. The ductus arteriosus was closed.

Arising in the musculature of the right ventric immediately to the left of the aorta and immediate superior and anterior to the bulbus cordis, a very sm pulmonary artery was found. There was no communicati between it and the bulbus cordis. There were th malformed valves, suggesting arrested development about the third week of intra-uterine life; immediately dis to these the pulmonary artery widened slightly.

Abdomen: Spleen slightly enlarged, congested, no infa tion. Liver slightly enlarged, congested. Kidneys norma stomach and intestines normal.

Brain: Covering the vertex of the brain and extendi down to the base was a quantity of green pus. The bra substance appeared somewhat insected, but otherw normal. The fluid in the ventricles was clear. In the rig posterior temporal region, lying deep to the lateral ventric was a localised abscess cavity, measuring 1½ in. by 1½ i containing fluid thick green pus.

Discussion.

The case is of interest in many ways. Clinically has been studied over a period of ten years. Consid ing the cyanosis and the associated polycythæmia the dominating factors, polycythæmia rubra, Vaque disease, and polycythæmia secondary to a congeni heart defect constitute the initial differenti diagnosis. The history, particularly the age at whi the first symptoms were manifested, excludes primary polycythæmia. In 1888 Fallot [1] point out the "tetralogy" of pulmonary stenosis, int ventricular septal defect and dextraposition of t aorta with hypertrophy of the right ventricle as t commonest underlying condition in patients wi congenital cyanosis who reach adult life; he not that cyanosis is usually absent in cardiac defec without associated pulmonary stenosis. The ca described is one of congenital cardiac defect due arrest of growth before the different parts of the hea had been entirely formed. It falls into the "cyanotic group. The very marked cyanosis is characteris of those cases of congenital cardiac disease in whi there is a serious interference with the circulati leading to a pathological increase in the amount reduced hæmoglobin in the circulating blood. De cient aeration of the blood is the essential elemen right heart hypertrophy, increased respiratory activit and polycythæmia are developed in an attempt supplement the inefficient pulmonary circulatic Chronic asphyxia develops, with consequent periphe clubbing and retinal changes. In the various descri tions of such cases, and in the classifications of Ma Abbott and others, an enlarged heart and the presen of precordial thrills and cardiac murmurs are note Although a precordial thrill is present in many of the cases Rolleston accounted for the absence of thrill a somewhat similar case by the presence of a lar defect of the septum, through which the blood pass with ease into the aorta. This is the explanati which I offer in this case. The absence of abnorm cardiac murmurs is explained by the complete absen of blood in the pulmonary artery.

Repeated clinical, bacteriological, and radiologic examination revealed no evidence of pulmona tuberculosis. The hæmoptyses may have been due congestion of the pulmonary circulation, associat with a slight atheroma of the enlarged bronch arteries. The slight atheroma at the base of the aor was not, I think, incompatible with an acute termir infection.

The faints were probably cerebral anoxæmic attac Curious epileptiform attacks of a similar nature, in young man with a similar cardiac defect, have be described by Campbell Howard as apparently due a temporary thrombosis of the cerebral capillar produced by a high degree of viscosity of the pol cythæmic blood.

Cerebral abscess is a not uncommon complicatic It occurred six times in a series of 96 cases

[1] Fallot: Marseille Méd., 1888.

monary stenosis recorded by Abbott.[2] Similar cases recorded by Ballot, Peacock,[3] and others. The ebral abscess was probably due to an infective bolus of a paradoxical character. Owing to the sed pressure in the right chambers of the heart, ociated with dextraposition of the aorta and a ntricular septal defect, the conditions were favour- e for a crossed embolism from thrombi lodged within right auricular appendix, or the passage of gments from thrombosis in the systemic veins. primary focus was found.

n pulmonary atresia life is usually very short; the es with closed interauricular-interventricular septa die within the first few months of life. When a ect of the interventricular septum alone exists the ient may live some years. The highest age that I ve found in the literature is that of a child of 13, cribed by Peacock. The duration of life in monary stenosis with closed interventricular septa elatively high; a patient of Hallemand's died at age of 57, and the average recorded age for septal ects is 36.

consider the case described to be one of pulmonary esia which has survived until the age of 30.

should like to express my thanks to Sir Arthur ith and Dr. E. G. B. Calvert for their help, and to latter for permission to publish this case.

Clinical and Laboratory Notes.

A NOTE ON THE EARLY DIAGNOSIS OF PRIMARY PERINEPHRIC SUPPURATION.

By S. A. Lane, M.D. Dub.,
SURGEON TO THE BOGNOR WAR MEMORIAL HOSPITAL.

PERINEPHRIC suppuration in a previously healthy ividual is not common enough for any one surgeon have a preponderating experience in its diagnosis, l it is doubtful whether any other abscess can de detection for so long or pus form in any er situation in such phenomenal amount without iously jeopardising life.

These remarks are based on eight cases of primary inephric abscess of which I have kept note.

. In seven cases the diagnosis was so belated as to se danger to life, much suffering, and protracted illness.
. In seven cases the condition was right-sided.
. Pus was odourless in all; this contrasts with the cess secondary to empyema, appendicitis, or pyelitis, ere the pus is often offensive.
. In four cases there was a definite history of recent boils.
. *Staphylococcus aureus* and pneumococcus were the cting organisms most frequently found.
. All eight recovered satisfactorily.

t has been said that the diagnosis is usually y, but the mistakes made include neurasthenia, umatism, lumbago, hip-joint disease (four cases), positis, sciatica. In several cases the correct gnosis was not made until the usual signs of acute puration (severe pain, temperatures of 104° F., ors, and sweats) had figured prominently for eral weeks and a large swelling outside the border the erector spinæ muscle had directed attention the state of affairs. In two cases where ammation of the hip-joint was diagnosed the b was put in extension on an inclined plane; in instance this was maintained for six weeks and the other for about six hours.

Signs and Symptoms.

During the preliminary stage the patient feels ow par, is easily tired, and has no inclination for y sort of activity. In patients suffering from ls this condition was quite naturally and perhaps rectly ascribed to the boils. There was pain in the loin and often in the hip-joint, stiffness of the lumbar spine limitation of extension at the hip-joint, and bowing of the body to the affected side. This produced a gait aptly described in two cases as "walking like an old man."

Later, with the ordinary accompaniments of acute suppuration, pain became severe and the patient lay on the affected side with the thigh supported in flexion. Any attempt to extend the thigh caused much pain, referred to the hip-joint and down the thigh. Thoracic respiration was markedly accelerated, without the slightest dyspnœa or any signs of pulmonary trouble.

The appearance of a swelling to the outer border of the erector spinæ muscle is not necessarily late. If looked for carefully it may be detected at an early stage; later it becomes prominent and cannot well be missed.

Enlargement of the inguinal glands and the intra-abdominal glands along the iliac vessels was very marked in two late cases.

Diagnosis.

The preliminary stage described is often well marked; in one case it prompted a diagnosis of neurasthenia. Taken in conjunction with later signs it may be of value. Swelling at the outer border of the erector spinæ is probably the earliest reliable sign, but must be sought carefully.

The increased respiratory rate in the absence of signs in the chest, and the enlargement of the iliac and inguinal glands, point to the probability of retroperitoneal inflammation. A leucocyte count during the acute febrile stage should be of value in recognising suppuration. A screen examination of the diaphragm where there is respiratory frequency might be of value, but was not done in any of these cases.

A mistaken diagnosis of hip-joint disease was made in 50 per cent. of this series. This should be ruled out by noting that the patient often lies on the trochanter, and that the joint can be moved without discomfort in any direction so long as the iliopsoas muscle is not tautened.

Pain referred to the hip and thigh, in conjunction with the symptoms described, should direct attention to perinephric suppuration in the same way that pain at the knee may indicate disease at the hip.

A CASE OF GLASS FRAGMENTS IN THE KNEE.

By A. H. Bizarro, F.R.C.S. Eng.,
SURGEON TO THE S. FRANCISCO HOSPITAL, OPORTO.

THE interesting features of this case are (*a*) its clinical similarity with a case of external semilunar injury; (*b*) the absence of infective intra-articular reaction in spite of the presence of dirty glass within the knee-joint for a long time; and (*c*) the curious inframeniscal position of the foreign body.

The patient, a girl of 9, came to consult me on Sept. 18th, 1925, complaining of pains on her left knee and inability to extend it fully.

She fell down in her garden on Oct. 20th, 1924, and cut her knee. She apparently fell on the patellar surface of the joint with the leg flexed. There was a wound on the anterior surface of the knee half an inch from the outer border of the patella, and another at the back of the leg, behind the fibular head. These wounds healed up in three weeks. Ever since then the knee has felt "funny," and at times she was apparently unable to walk properly owing to pain on attempting to move the joint. Three weeks before coming to my consulting-room she felt acute pains in the joint, which was swollen for three days. A fortnight later another attack of swelling and pain forced her family to seek advice.

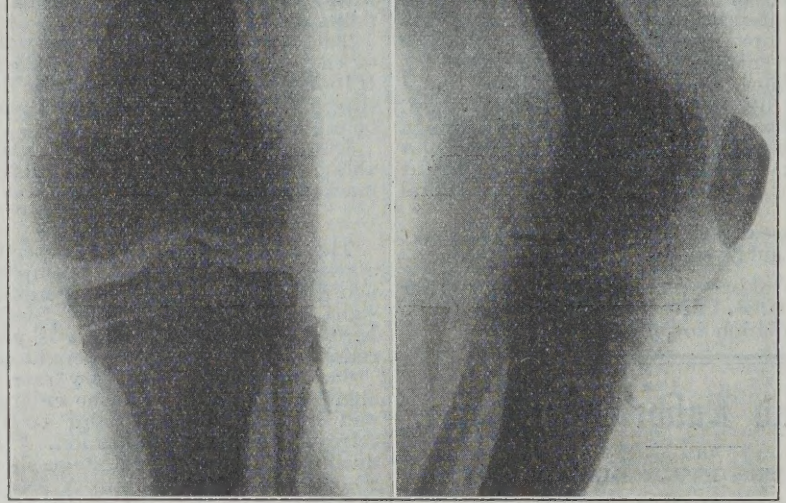
When I saw her the left knee was swollen all over. The swelling was within the articular synovial cavity. The scars corresponding to the wounds above mentioned were irregular and slightly cheloid. There was a spot of tenderness, on pressure, at the articular line, near the outer border of the patellar ligament and corresponding to the external semilunar cartilage. At the back of the joint, and behind the head of

U 2

Abbott, Maude E.: Modern Medicine, Osler and McCrae, ed., 1927.
Peacock, T.: On Malformations of the Heart, London, 1858.

the fibula, pressure elicited less severe pain. The attempt to extend her left leg fully caused severe pain in the joint. There were no signs of abnormal lateral mobility nor any particular line of radiation of the pains on passive or active movement of the knee. There were no constitutional symptoms and the temperature was normal.

A skiagram by Dr. A. D. Boto showed several foreign bodies in and around the joint. There was one, ½ inch long, between the external condyle of the femur and the outer tibial tuberosity. The lateral skiagram showed a group of three small foreign bodies above and behind, and another smaller one below and behind the first. These four were at the back of the joint and apparently fixed in the structures that limit the capsule posteriorly. Another, triangular in shape and about 1 inch in length, lay at the back of the upper end of the fibula pointing downwards and slightly outwards. The bodies were apparently glass. The patient recollects falling through a greenhouse window.



Radiogram showing glass fragments in the neighbourhood of the knee.

On Sept. 23rd, 1925, under open ether, the joint was opened by Sir Robert Jones's technique. A tourniquet was applied and the leg was kept flexed. A 5-inch incision was made, 1 inch to the outer border of the patella, avoiding the scar. There was some free yellowish synovial fluid. There were no free foreign bodies within the articular cavity. The external meniscus was uninjured and the surface of the crucial ligaments seemed normal. I much regretted not having divided the patella. I then explored under the meniscus with a Cooper's needle. To my satisfaction t linear body seen in the X ray photograph presented at t posterior limit of the external semilunar cartilage. It w triangular and broken at the apex. The Cooper's nee moved it freely to and fro until, after some tedious exerti it got round into the joint cavity. I did not try to whether it glided forwards on flexing the leg as I feared absorption. It was not possible to find the four smal bodies. The syn vial membra and capsule w stitched w ultratan cat No. 0. When anterior wou had been dres the big triangu foreign body v easily removed a longitudin incision throu the skin and of the poplit space.

The two pie of glass proved be of the ch window varie The four sma pieces left beh apparently longed to intra-articu piece which v removed. seems that joint moti pushed its sh end through posterior lig ments, break the four sm pieces off sharp end.

The skin wounds took four months to heal complet There was no intra-articular reaction, and convalesce was otherwise uneventful. The patient regained range of painless articular motion and the joint is f from fluid.

My thanks are due to my surgical assistant, M Estrada, and to my chief sister, Miss Flora, for after-care of the case.

A NOTE ON JAUNDICE FROM FOCAL NECROSIS OF THE LIVER.

By C. E. Newman, M.D. Camb., M.R.C.P. Lond.,
MEDICAL REGISTRAR, KING'S COLLEGE HOSPITAL.

Some time ago, while arranging the notes of cases of catarrhal jaundice on which I had done van den Bergh's test, I was struck by a curious coincidence: all those cases in which the condition had appeared as an intercurrent disease in patients already in hospital fell into one of two categories. They were either surgical or obstetric cases which had been under chloroform and had been to some extent septic. They were all diagnosed as "catarrhal jaundice" or "ascending cholangitis," but it seemed so odd that these conditions should be confined to two such limited groups in a general hospital that a more searching investigation was undertaken.

Earlier cases included a pneumococcal septicæmia following a mastoid operation, an appendicitis with peritonitis, an operation for hernia followed by rigors, and a forceps delivery, in all of which chloroform had been used, but the notes are not sufficiently detailed to justify inclusion. The following are the details of the more fully investigated cases:—

Case 1.—Female aged 44. Operated on under chloroform and ether for carcinoma of the breast on May 29th, 1925. On the 31st she was feeling ill (she had vomited a good deal after the anæsthetic), and had acetone and bile in the urine. Her conjunctivæ were distinctly yellow, and the van den Bergh test on the same day gave a prompt reaction 21 units. The fæces contained bile. Next day there definite systemic jaundice. By June 4th the jaun had almost disappeared and there was only a trace bilirubin in the urine, but no bile salts. She recov completely.

Case 2.—Female aged 39. Delivered of a macera fœtus under chloroform on Oct. 12th, 1925. Wasserm reaction positive. She had a high intermittent temperat with rigors until the 20th. The blood culture was un tunately contaminated. She became jaundiced and vomi on Oct. 19th, with definitely pale stools and bile in urine. The van den Bergh test on the 22nd gave a pro reaction and 6·5 units. The jaundice faded slowly as general condition improved, and she went out well.

Case 3.—Female aged 16. Operated on for tonsils adenoids on Feb. 22nd, 1926, and on the 28th for mastoid having eaten very little carbohydrate in the meanti Chloroform was used on both occasions. She was ill after the second operation, with a high swinging t perature and much vomiting. On March 2nd she bec jaundiced and delirious, with much acidosis. There no bile in the urine. The van den Bergh test gave a pro reaction and 7 units. Bile appeared in the urine for first time, and in large quantities on the 5th. A hæmol streptococcus was isolated from the mastoid, from erysipelatous inflammation on the arm round a needle p and from a septic arthritis of the ankle-joint which develo on the 17th. She was treated by immuno-transfusion an autogenous vaccine, and ultimately recovered. The ja dice faded on the 19th.

Case 4.—Male, aged 49, admitted to hospital on July 2 1926, with a three weeks' history of pain in the t and rigors, intensely jaundiced, and with every appear of septicæmia. The abdomen was distended, with t recti, and tenderness was felt over the splenic area.

ne contained blood and albumin, but no bile, and there s a polymorphonuclear leucocytosis. The van den Bergh ction on admission was prompt, with 3·8 units. Bile ts appeared in the urine next day, and a considerable antity of bile pigment. Death took place from septi- mia of unknown origin three days later. Blood taken art puncture immediately after death gave a prompt n den Bergh reaction and 3·2 units.

At the post-mortem examination a huge perinephric scess was found, with abscesses in the kidney from which *Staphylococcus aureus* was isolated, and a right upper ar pneumonia. The liver was large and very fatty, l the microscopic sections gave a clue to the pathology the jaundice. The bile-ducts were apparently quite althy, but the portal spaces were slightly infiltrated with nd cells and polymorphonuclear leucocytes, not in ecial relation either to the portal veins or the hepatic eries. The whole liver was full of small, irregular, ttered areas of degenerated cells, many of which had ie on to complete necrosis. These areas were mainly the outer and middle zones of the so-called lobules. ere necrosis had taken place the bile capillaries in the tre of the columns of liver cells were thrown up against blood capillaries and separated from them only by their lothelial lining and possibly the remains of the cell walls the disintegrated liver cells. That is to say, there was thing separating the two but a permeable membrane, ough which bile pigments and salts could diffuse from the her concentration of the bile to the lesser concentration the blood, thereby producing a blood serum similar to t in cases of obstructive jaundice, and explaining the mpt van den Bergh reaction without invoking a hypo- tical mechanical obstruction by catarrh or inspissated e. There was, indeed, no evidence of obstruction, croscopic or microscopic.

CASE 5.—Female, aged 28, who had miscarried of a three nths' child on July 31st, 1926, was admitted with tetanus August 4th. She was given chloroform daily to control spasms from the 5th to the 10th, and serum treatment. the 12th she became jaundiced and had bile in the urine, l the liver was enlarged. She never vomited. The van n Bergh reaction was prompt, with 11 units. On the h, when the jaundice was just beginning to fade, the ulose tolerance test gave the following result:—10 A.M.: od-sugar, 0·109, 30 g. lævulose given fasting. 11 A.M.: od-sugar, 0·150; 11·45 A.M.: blood-sugar, 0·150. Blood en from the uterine cavity was sterile. The jaundice was visible on August 17th, and the last trace of bile in the ne was found on the 24th. She made a good recovery.

CASE 6.—Female, aged 23, admitted in labour on gust 24th, 1926. She had been vomiting for 48 hours viously and had eaten nothing, but had shown no other sign pregnancy toxæmia. She was delivered on August 25th, l a post-partum hæmorrhage, and was under chloroform an hour and a half for the repair of a torn cervix. She l also had a little chloroform during labour. She vomited reat deal next day and was obviously very ill. Fifteen rs after delivery she was jaundiced; the urine contained ttle acetone and albumin, but no bile, and the van den gh test gave a prompt reaction and 7 units. On gust 27th she vomited less, but was very collapsed and an to show petechial hæmorrhages in the mouth. Next day died, with œdema, fibrillary twitchings of the muscles, l air-hunger. Just before death the urine contained a le albumin, but no acetone; unfortunately no tests for were applied.

The post-mortem examination revealed many petechiæ ler the serous membranes, and bile-stained peritoneal l pleural exudates. The kidneys were engorged and a le bile stained. The liver weighed 2 lb. 11½ oz., and was mpletely and uniformly fatty in appearance, but with eculiar rubbery consistency and no bulging of the liver stance over the capsule. There were no interstitial morrhages and the capsule was tense. The sections wed gross fatty change, most of the cells being full of , and in the zone of the lobule intermediate between the tal and efferent veins the change had gone on to complete chy necrosis, the appearance being very similar to that Case 4, but more intense and different in distribution. e only healthy cells were those related to the portal veins. this case, also, there was no macroscopic or microscopic dence of obstruction to the bile-ducts. Blood taken t mortem gave a prompt van den Bergh reaction and units.

These two cases both present the syndrome of ndice giving the prompt van den Bergh reaction thout obstruction, but with focal necrosis in the er, one of them being caused by sepsis alone and other by chloroform alone. It therefore seems re than probable that those other and commoner ses, in which both agents play a part, have a similar pathology. Unfortunately, since no such case has yet come to autopsy, I have had no opportunity of examining liver sections.

In one more case necrosis caused by chronic venous engorgement also produced, apparently, a prompt reaction type of jaundice.

CASE 7.—Female, aged 32, an old-standing case of mitral stenosis and adherent pericardium of rheumatic origin, was admitted on June 22nd, 1926, with severe back-pressure signs and definite jaundice. She had a prompt van den Bergh reaction and 6·5 units. At the post-mortem exam- ination were found an advanced nutmeg liver, all the signs of cardiac back-pressure, and a bile-stained ascites. There was no obstruction to the bile-ducts and the fæces were of normal colour. The liver sections showed extreme venous congestion and fatty degeneration, and considerable necrosis around the efferent veins.

Conclusions and Summary.

Chloroform and sepsis, either alone or, more commonly, acting in conjunction, can cause a paren- chymatous degeneration of the liver. This process may go on to actual necrosis of liver cells, and there seems to be a group of cases of jaundice, clinically and biochemically "obstructive" in type, in which there is no obstruction to be found post mortem, and in which the jaundice appears to be due to absorption of bile into the blood stream through the capillary endothelium in the areas of necrosis. These cases fall into the "toxic-infective" type of jaundice, and I believe that this mechanism would explain the pathology of the whole of that group more adequately than any other theory. The same process explains the "obstructive" type of jaundice which occasionally appears in the terminal stages of cardiac failure. A point of practical importance is that all the cases described above, in which jaundice followed chloroform administration, had been "prepared" for the anæsthetic by starvation and purging. Con- sidering how susceptible the liver is to poisoning when depleted of glycogen, it would seem wise to ensure an adequate glycogen store by previous administration of glucose, rather than to run an additional risk by starving the patient.

I should like to thank Sir Charlton Briscoe, Sir Lenthal Cheatle, Mr. Arthur Cheatle, Dr. C. F. T. East, Mr. W. Gilliatt, and Mr. A. C. Palmer for their kind permission to publish these cases.

Medical Societies.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

RELATION OF SYPHILIS TO MALIGNANT CHANGES.

A MEETING of this Society was held in London on April 27th, with Sir HUMPHRY ROLLESTON, the President, in the chair.

Dr. ARCHIBALD LEITCH spoke on Syphilis in Relation to the Ætiology and Diagnosis of Malignant Disease. He said the manifestations, complications, and sequelæ of syphilis were so varied that it was not surprising to find that disease advanced as a pre- disposing, exciting, or contributory factor in malignant disease, especially as so comparatively little was known as to the causes of the latter. The idea seemed to be that syphilis left behind it a tissue the resistance of which had been so lowered that it easily became the seat of cancer. There were still some who expected that the cause of cancer would prove to be a parasite. The Wassermann reaction was largely an impersonal criterion, but not altogether so, though the proportion of borderline cases was admittedly small. The fact that the

Wassermann reaction was positive in a particular patient did not necessarily mean that a particular lesion found in that patient was syphilitic in nature. The statement was often made that malignant disease had supervened on the site of an old syphilitic ulcer, but he wondered whether that was an instance of an oft-quoted alleged occurrence. A French author put the matter very definitely by declaring that "syphilitic persons are potential candidates for cancer, and live for ever beneath a sword of Damocles." Dr. H. J. B. Fry, of the Cancer Hospital, London, had taken 761 cases of cancer and tested them for syphilis, comparing this with 720 non-cancerous cases in the same hospital practice. Of the former 8·7 per cent. and of the latter 10·7 per cent. gave a positive Wassermann reaction. This did not seem to make the relationship of the two diseases very definite. The case seemed to be strengthened, however, by taking each organ or tissue of the body separately, as Dr. Fry had done. For example, in cancer of the cervix and uterus, 13·3 per cent. gave a positive Wassermann reaction; in cancer of the buccal cavity 13·2 per cent. were positive, while in cancer of the tongue 31 per cent. were positive. Leucoplakia was frequently present in epithelioma of the tongue. Was syphilis the causative factor in this leucoplakia which later became malignant? Bruck had done the Wassermann reaction in 12 cases of leucoplakia, and had found it positive in 10. Leucoplakia of the vulva was said to become malignant almost invariably. Figures for the breast failed to show any connexion between the two diseases, and only 3 per cent. of cases of cancer of the rectum were syphilitic. Syphilis of the rectum was, in fact, a very rare disease. In the series 15·4 per cent. of cases of malignant disease of the stomach gave positive Wassermann tests. The late Sir C. Ryall, who had a large experience as surgeon to the Cancer Hospital and the Lock Hospital, found that 80 per cent. of cases of lingual cancer gave a history of syphilis, a figure which closely approximated to that reported by Fournier. Ryall believed that smoking in a person with a syphilitic tongue was the cancer determinant. It was really a vicious circle. Dr. Leitch referred to experiments of his own on tobacco extracts, and quoted the experiments of Brown and Pearce in which carcinoma had developed on syphilitic lesions in rabbits.

Discussion.

The PRESIDENT said his own impression was that squamous-celled carcinoma seldom developed as a result of chronic syphilitic lesions, and even less often than on lupus. Dr. Leitch's figures suggested that squamous-celled carcinoma was more prone than the more highly differentiated carcinoma to occur in syphilitic subjects—e.g., there was a contrast between squamous epithelioma of the tongue and malignant disease of the stomach. Was it possible that syphilis more efficiently destroyed the activity of columnar than squamous cells? He agreed that cases regarded as syphilitic stricture of the œsophagus usually had squamous-celled carcinoma. It would be interesting if Dr. Leitch could give the figures for chimney-sweep's cancer. McNee had brought forward two cases in which gumma of the stomach imitated carcinoma, and Sir Humphry had always thought that chronic ulcer of the stomach might occur more often in persons with syphilitic endarteritis than in ordinary people.

Colonel L. W. HARRISON said that he had always considered that the binding factor was chronic irritation. It was well known that syphilis tended to recur on a damaged spot, as was well shown by chronic syphilitic glossitis. In the past, the latter condition was less commonly seen in women, because men more often irritated their mouths by smoking and strong alcoholic drinks. This difference might well vanish with women's changing habits. In the case of cancer of the tongue, it was easy to understand the stages: syphilis, sensitive areas, the irritation of tobacco, perhaps a rough pipe—and, on such areas, cancer. One of the best illustrations he knew of this irritative cause of cancer was furnished by the Kashmiris, who carried a small fire-basket pressed against the abdomen for warmth in the mountains. These people frequently developed cancerous ulceration on the abdominal wall. He thought it was generally agreed that there was a close relationship between syphilis and cancer of the tongue. The subject of syphilis of the cervix had not been very fully worked out.

Dr. DAVID NABARRO questioned the wisdom of relying on the Wassermann report as infallible evidence of the existence of syphilis, as he frequently received a negative report concerning the fathers of children known to be syphilitic. In his own clinic 70 per cent. of the fathers of syphilitic patients were reported to have a negative Wassermann.

Dr. F. C. DOBLE said that epithelioma of the lower lip was quite common in Cornwall, a county where syphilis was very rare. In 14 cases in which the cancer was excised and examined the blood Wassermann was negative. In Cornwall the cancer was attributed to the fisherman's habit of holding the lines in the mouth. The irritation might be due to the tar on the lines or to the pull on them by the fish when hooked.

Dr. LEITCH replied.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on May 3rd Dr. DONALD HALL, the President, took the chair and Dr. C. G. SCHURR read a paper on

Myopia in Childhood.

He said that the four theories most widely held about the causation of myopia could be considered under two headings, Posture and Predisposition. Under the first came (1) excessive convergence, and (2) the effect of gravity; whilst factors of predisposition were: (1) a small ciliary body, and (2) diminished resistance of the sclera. An examination of the first three of these showed that in the end they were dependent on the fourth. Without an abnormal distensibility of the sclera they could not of them be deleterious in their action. Heredity might undoubtedly be a contributory cause of diminished scleral resistance, but it did not account for those cases, by no means uncommon, in which there was no history of myopia in the family, or indeed even a history of hypermetropia. An investigation of the height and weight curves of myopic children in the Barclay Home, Brighton, suggested that there was a definite relationship between myopia and metabolism. A series of graphs of contrasting cases showed that where myopia was found to be increasing, there was always a falling-off in the weight and height ratio compared with the normal. This condition was not found where the myopia was stationary, even if corneal nebulæ were present. The material so far available had not proved sufficient upon which any firm conclusions could be based, but it afforded ground for interesting speculation. Dr. Schurr concluded by considering the question of the future of children who attended myope schools. The establishment of workshops, where they could compete with persons of like disability, seemed more reasonable and less wasteful than sending them out to compete with normal persons. The early detection of myopes was an important duty of medical officers in charge of schools, and practitioners could give useful advice on such matters as suitable exercise, food, sleep, and the choice of profession.

LEAGUE OF NATIONS PUBLICATIONS.—The department of Messrs. Constable and Co. (10, Orange-street, London, W.C.), which is concerned with the issue in this country of the official publications of the League of Nations, has been placed under the charge of Mr. P. Savary, who has been associated with the information section of the League for over four years.

CONFERENCE ON RHEUMATIC DISEASES.

BATH, MAY 10TH–11TH.

THE Conference on Rheumatic Diseases held in ath last week came to a satisfactory conclusion on riday, May 11th, and all who took part in it were nanimous about two things—that as a business eeting it had been a marked success, and that the portunity for fellow-workers to meet, afforded by e amenities of the City that had issued the summons, as unrivalled. The spirit in which those amenities ere accepted by the congressists showed their full d unanimous appreciation of their reception. The nference closed with a unanimous vote of thanks Mr. Edric Chivers, the Mayor of Bath, alike for e profuse hospitality granted by the City and for s own personal endeavours to carry out the objects the Conference. The passing of the vote of thanks the Mayor was accompanied by an acknowledgment the particular debt of gratitude owed to the Lady ayoress, Mme. Sarah Grand, and to the Organising mmittee, Dr. F. G. Thomson, Dr. Rupert Waterouse, Dr. R. G. Gordon (President of the Bath anch of the B.M.A.), Dr. Vincent Coates, and Mr. hn Hatton, the director of the Royal Baths, who ted as organising secretary.

THURSDAY, MAY 10TH.

The Conference was opened by a Civic Welcome om the Deputy Mayor, after which Sir GEORGE EWMAN (Chief Medical Officer to the Ministry of ealth) delivered the brief Presidential Address to the nference which we were able to publish last week. mediately thereon the Conference got to business, e first Session, devoted to the Social Aspects of eumatism, being opened by the President of the ssion, Lord DAWSON.

FIRST SESSION—SOCIAL ASPECTS.

After a few introductory words from Lord DAWSON, e first paper was read by Sir WALTER KINNEAR ntroller to the Insurance Department of the nistry of Health), who dealt in a clear and eresting manner with the problem of the cost to e country of industrial rheumatism. This paper, ich is published on p. 1001 of this issue of THE NCET, revealed what a burden both to themselves d to the community are our large number of umatic subjects, and proved how urgently needed s the attempt of the Conference to arrive at some finite conclusions regarding ætiology and the propriate methods of prevention and relief.

Sir Walter Kinnear was followed by Dr. H. B. ACKENBURY (Chairman of Council, B.M.A.), who oke on the need for the organisation of the facilities treatment for the whole population. These ilities included: (1) the discovery and elimination any infected foci; (2) the administration of drugs; d (3) the use of various physical agencies and thods. "The right case must be got to the right ce for the right purpose." Dr. Brackenbury erred to the work which had been done in Holland d in post-war Germany towards this end. He thered that these continental organisations were not any means perfect but that we had something to rn from their experience. In this country specialist vice was only at the disposal of a small percentage insured persons, and it should be made part of the tutory medical benefit as soon as possible. Two actical schemes for the organisation of rheumatic atment were before the public in this country—, that of the British Red Cross Society and that the British Spa Federation. In order to secure the arty support of the medical profession these schemes ould be united and should conform to certain quirements—e.g.: (1) no patient should be ated except on the recommendation of a medical actitioner; (2) patients, who could easily obtain e requisite treatment should be refused; (3) the conditions should envisage the possibility of a patient obtaining advice at the consulting-room of a specialist instead of at an institution; and (4) there should be suitable opportunity for practitioners to observe and obtain experience of the methods employed and their results. Such organised schemes would afford opportunities for the clinical and pathological observation and research which were essential for success in combating this baffling and obstinate national scourge.

Dr. J. VAN BREEMEN (Holland), Hon. Secretary, International Committee on Rheumatism, spoke on the types of rheumatic disorders which were most prevalent in Holland. He said that official statistical data on rheumatism were an unknown quantity in Holland, and that the scientific study of the social campaigns against rheumatism were still in their infancy. He submitted a table with regard to 832 male and 1046 female rheumatic patients, attending the Rheumatism Consulting Bureau at Amsterdam during 1927, classified according to the type of their disease. He thought that acute rheumatism was comparatively rare in Holland, as also heart disease and chronic joint disease following acute rheumatism. The number of children, who had died in Holland of acute endocarditis and myocarditis between the ages of 5 and 14 appeared to be much less proportionately than the corresponding fatalities in Great Britain. Gout was also rare in Holland, though the old French Huguenot families often showed the arthritic diathesis in a pronounced degree. He found that affections of the knee-joint were strikingly more frequent in women than in men, and that the shoulder-joint was more frequently affected in men. Arthritis deformans, the equivalent of rheumatoid arthritis, was not very frequent in Holland, and his impression from studies in England was that the cases in England were more numerous and more severe. Cases of sciatica over the age of 50, sent to him, were often really osteo-arthritis of the hip-joint. Arthritis of the spine was seldom recognised and was more common than was formerly thought, though its prognosis was less grave. The strict separation of spondylitis deformans and rhizomelic spondylosis (complete vertical ankylosis) was frequently impossible. Arthritis of the spine generally occurred in men and he had never seen the rhizomelic forms in women. He considered that the influence of occupation in producing rheumatic affections would be one of the great medical problems of the future. The statistics of the "Councils of Labour" (Raden van Arbeid) showed that only about one-tenth of the working people invalided by chronic rheumatic diseases were medically treated. He hoped that within the next few years it would be possible to furnish official statistics with regard to all rheumatic affections in Holland.

Dr. J. ALISON GLOVER gave particulars from the Ministry of Health's inquiry, which had reference to a sample population of about 90,000 insured persons, and indicated that the percentage of the total sickness caused by rheumatic diseases was about 16·8 for males and 14·4 for females. The lower percentage among women was due to the younger age of the insured women, owing to matrimony and other reasons. The Leipzig statistics, published in 1907, seemed to indicate that rheumatic diseases were quite as common in Germany as in England, and this impression was confirmed by the more recent figures given by Sommerfeld for Berlin. The fact that the incidence of acute rheumatism was undoubtedly declining in our country was one of the bright spots of the problem. Dr. Lambert had shown that this decline was also occurring in the experience of the New York hospitals. The figures for our Navy from 1907 to 1923 showed a great decline in rheumatic fever, out of all proportion to the slight fall in the incidence of tonsillitis. These figures, however, referred to frank rheumatic fever, and gave no idea of the incidence of other manifestations of the rheumatic infection in children, which were almost equally important from the point of view of the

production of heart disease. Probably 1 in 50 of the children attending the public elementary schools required observation and periodic examination on account of some rheumatic manifestation. Dr. Glover, who showed diagrams which indicated the attack-rate at various ages in both sexes from fibrositis and arthritis, referred to the marked effect of occupation upon the incidence of rheumatic diseases and specially referred to the observation of van Breemen that every special trade had its own rheumatic "deviation." So far our Ministry's investigation had only brought out the fact of the special incidence of osteo-arthritis upon the workers in the heavy metal trades. The statistics of hospitals showed that they were only able to admit and treat a very small percentage of the cases of chronic arthritis, and further institutional treatment was obviously needed to provide accurate attention to septic foci, and the intensive local and physical treatment which might be given at a spa hospital or an out-patient clinic. The number of insured patients suffering from chronic arthritis was only half that of those who suffered from fibrositis, but the longer period of disablement caused by the former made the two equal in causing disablement. Thus the drain upon the National Health Insurance funds for sickness and disablement benefit caused by rheumatic diseases was at least one-seventh of the whole, one-half of which was due to chronic arthritis.

Dr. R. G. GORDON (Bath) laid emphasis on the fact that in almost every case of chronic rheumatic disease the skin is at fault in some way or another. Sweat secretion depended upon the sensory stimuli impinging on the skin, a good cutaneous blood-supply, and proper endocrine balance. A humid cold atmosphere made adequate sweating difficult. People who had spent their lives in a tropical climate when they returned to this country had lost their power to sweat and frequently developed fibrositis and panniculitis. Fatigue was an important factor. As an example of local strain, we had the lumbago of gardeners, the fibrositis of the shoulders and backs of miners, and the osteoarthritis of the hips in those who had ridden and hunted much, but general fatigue markedly influenced the endocrine system and through it the action of the skin. In treating chronic rheumatism it was necessary to find the fatigue limit of the patients and to keep them within it. Emotion, worry, and depression also affected the endocrine system and the action of the skin.

Dr. HANS JANSEN (Copenhagen) said there were no statistics available as to the relative prevalence of rheumatic diseases in Denmark.

A further important paper was read to the Session by Dr. REGINALD MILLER, which will be found on p. 1005. This paper dealt with the influence of environment on rheumatic infection in childhood, and its conclusions formed the topic of comment in many of the communications which followed.

Lord DAWSON closed the debate with a short reflection on the general messages conveyed by the speakers. Alluding to the incidence of fatigue, he said that everyone, and not only medical men, recognised the magnitude of the evil caused by chronic rheumatism among workers, adding that it was necessary not merely to think of the many days of sickness and the heavy loss of life, but also to think of its affecting the quality of life. It was clear that environment played a prominent part in the production of rheumatism and the allied sequelæ, though occupation played its part, as had been shown by the speaker who had pointed out how metal workers were particularly subject to rheumatic diseases. And while he deplored the idea that they should be characterised as poverty diseases only, he urged the importance of the improvement of housing, of the methods of domestic life, of good clothes, and of the open-air life. While strongly advocating the value of recreation, and of playing rather than watching games, and of guarding against anything like fatigue, he ventured to raise the issue as to whether the rigid idea of the eight-hour day was wise, and thought it might be better to have occasionally a longe working day, properly alternated with a shorte provided the average of the eight-hour day was n exceeded during the week.

FRIDAY, MAY 11TH.

SECOND SESSION—CAUSATION.

The second session of the Congress was opene punctually at 9.30 A.M. by Sir HUMPHRY ROLLESTO who delivered the following

Presidential Address.

To begin with, he asked the Conference to consid what were the connecting links or common ætiologic factors in the rheumatic disorders. At one end of t scale was acute rheumatic fever whilst at the oth was osteo-arthritis, largely a degenerative disea Between these two extremes was a chain of gradu transitions, but clinically the main distinction w between the acute and subacute forms of disea prone to damage the heart and to react to salicylat and the chronic forms, permanently damaging t joints, but seldom, if ever, the heart, and irresponsi to salicylates. Did chronic joint inflammation devel often enough in persons formerly attacked by rhe matic fever to suggest that the two diseases were d to the same infection, or was the sequence mo credibly explained by the supposition of a gene arthritic diathesis? The characteristic lesion rheumatic fever, including chorea, was the formati of nodules, large in the subcutaneous tissues, su miliary in the heart. These also occurred in rheumat arthritis, but had rarely been reported in oth disorders. The submiliary nodules in the myocardiu (often called Aschoff's bodies) were generally regard as pathognomonic of acute rheumatic infectio though Geipel and Butterfield dissented and Cow and Ritchie stated that they occurred in most of t acute infections. Nodules of this kind were found the pericardium, cardiac valves, synovial membran of the joints; Coombs had described changes in t aorta and nodular periarteritis (1908–09), and Klo has commonly found arterial lesions in acute rhe matism—an inviting subject for further research.

According to Coates and Coombs the histologi structure of the subcutaneous nodule in rheumat arthritis and Still's disease was the same as Aschoff's submiliary nodules in the myocardium.

Subcutaneous nodules had been often found rheumatoid arthritis and osteo-arthritis, which Hawthorne to say in 1912 that "either rheumat arthritis is rheumatism or the development of fibr tumours in the subcutaneous tissues is not a spec note of rheumatism." But Sir Humphry Rolles had not found any evidence of submiliary nodu in the heart in chronic rheumatoid arthritis. Fib sitis, which was the non-arthritic form of chro rheumatism and might have the local habitation a name of panniculitis, was also accompanied by nodu formation, though in this condition the thickeni were not so histologically characteristic as rheumatic nodule. As Stockman and Weber l pointed out, panniculitis, like fibrositis and fib myositis, might arise from various causes.

The much debated streptococcal nature of ac rheumatism, first raised by Poynton and Paine in 19 had, in spite of much criticism, been steadily gain ground. Recently Small had described as the spec cause a non-hæmolytic streptococcus, differing fr the *viridans* group in its cultural characters, under name of *Streptococcus cardio-arthritidis*. His spec treatment with antiserum and vaccine of 72 ac rheumatic, 25 choreic, and 40 chronic rheumat cases had given encouraging and significant resu There was a widespread impression that chr rheumatoid arthritis and its allies were due streptococcal infection, though Warren Crowe incri nated *Staphylococcus albus*, type D, for rheumati arthritis and streptococci for osteo-arthritis non-articular rheumatism. It might be argued t the various members of the rheumatic diseases v streptococcal in origin, their clinical and struct

ifferences depending on (*a*) variations in the "seed," nd (*b*) inborn or acquired differences in the soil—amely, the constitution, endocrine, and other factors. he non-infective origin of chronic articular lesions, ıch as metabolic anomalies in alkaptonuria, in the ·ophic (e.g., Charcot's arthropathy), and psoriatic ›rms might still be a matter for discussion, and in ıese, at any rate, it seemed that, if there were bacterial ıvasion, it was secondary and subordinate in import-nce. In both the acute rheumatic and the chronic ıeumatoid forms hereditary constitution or an arthritic diathesis" must be considered to play a art. Inadequacy of the thyroid had been specially ut forward, but ovarian and pluriglandular inefficiency ad also been regarded as responsible. Pemberton had sisted on the low sugar-tolerance of chronic arthritics ıd ascribed this to diminished circulation of blood in ıe muscles. But the possibility should be borne in ind that both the disturbed endocrine function and ıe arthritic manifestations were due to infection; ›r example, the correspondence between the geo-·aphical distribution of endemic goitre and of ıeumatoid arthritis (McCarrison) might be explained ; different results of an underlying infection. In escribing the loss of sulphur in chronic rheumatic ·thritis Cawadias concluded that the toxic and fective, and even physical factors, such as damp, sponsible for rheumatoid arthritis first acted on the ·gans—liver, thyroid, and autonomic nervous ·stem—regulating metabolism. On the whole it ight be reasonable to suggest that varying degrees diminished constitutional resistance of the fibrous ssues or of sensitisation to infection on the one hand, ıd on the other hand the action of different kinds streptococci might explain the different clinical anifestations seen among the diseases grouped for ›nvenience under the heading of rheumatism.

Dr. C. WILFRED VINING (professor of children's seases, University of Leeds) described an investi-ıtion carried out in Leeds, by Dr. Wear, by the ıildren's almoner of the infirmary, Miss Finlay, ıd others, which confirmed his view that the ank rheumatic child is a child suffering from toxic ·bility with added rheumatic infection. He gave ırticulars of the symptoms of the "toxic debility" ıildren, including nervous instability, limb pains, ·adache, listlessness, and anæmia, and pointed out ıat some 25 per cent. of the child population belonging the social sphere from which rheumatism chiefly ›mes show these phenomena more or less. These toxic debility" children exhibit certain intestinal mptoms associated with mucus in excess and embranous material in the stools. The actually eumatic children suffer in the same way. Prof. ining was impressed with the similarity of the mptoms shown by these sufferers and by McCarrison's onkeys and pigeons fed on diets deficient in tamin B. He considered that a dietetic theory plains why rheumatism does not appear until ›r 5 years of age—that is to say, the dietetic deficiency kes some years to break down the defence. He found e family incidence of both toxic debility and eumatism easily explained by the family diet. ı Leeds he had found nothing to support the belief at damp plays an important part in rousing the eumatic infection to activity. On a recent visit to olland he understood from Dutch medical men, ho were also school medical officers, that, while ıorea, joint rheumatism, and cardiac affections were re in Holland, enlarged tonsils and adenoids were tremely common. He concluded that most children ho develop clinical rheumatism have a previous fective health history for months or years, which is ›ught about by prolonged dietetic deficiency, either vitamin B or in protein in conjunction with excess carbohydrate, or possibly by both these factors. e explained the sequence of events by dividing the ementary school-children into four main groups:) healthy children, comparable to those in other cial spheres; (2) children who are beginning to perience the results of the deficient diet and are ıder weight, with toneless tissues and alimentary canal disturbances; (3) children with added symptoms of toxæmia; (4) children with clinical rheumatism, acute or subacute, the dividing line between groups (3) and (4) being one of massiveness of dose, repetition of dose, or lowering of resistance by some factor or factors unknown. He maintained that if his conception is right we shall not prevent rheumatism by concentrating on damp houses and the removal of tonsils and adenoids, but rather by the provision of a well-balanced diet from infancy onwards. Prof. Vining did not rule out the possible effect of damp houses nor deny that the tonsils may be the portal of entry, but held that an exclusive throat ætiology is not warranted by the evidence at our disposal.

Dr. H. DINGWALL FORDYCE (hon. physician, Royal Liverpool Children's Hospital) expressed himself as largely in agreement with Prof. Vining as to the importance of a proper diet from infancy onwards. Although heredity might be of some importance, we were granted a postnatal interval of opportunity, lasting for several years, in which to develop effective prophylactic measures. Dr. Fordyce gave, as three important predisposing factors, instability of the nervous system, digestive disorder, and weakness of lymphoid defence, and sketched some of the home conditions likely to conduce to these factors. He considered that child welfare work, by its educational influence, had been one of the chief causes of the decline of acute rheumatism. A close coöperation was needed between the administrators and the clinical physicians. If we had at our command more beds in country hospitals and suitable residential schools he felt that the results would be remarkable.

Dr. CAREY F. COOMBS (physician, Bristol General Hospital) in a review of the bacterial position, submitted evidence that rheumatic fever is an infection rather than an intoxication, and that the disease is due to the invasion of the brain, joints, heart, and subcutaneous tissues by streptococci, which are borne thither by the blood stream. He thought we might accept the view that the tonsil is certainly, and the intestinal mucosa possibly, to blame for admitting this virus into the systemic circulation. The type of infection in childhood was, he held, best described as a series of raids, many of which are stealthy—the organisms linger outside the circulation and revisit the circulation from time to time. Dr. Coombs went on to refer to the work of Homer Swift and others which suggested that rheumatic patients showed a group sensitiveness to streptococcic toxins. This would explain why *Streptococcus viridans* succeeded in implanting itself on valves already injured by the rheumatic streptococci, and also the remarkable relation between scarlet fever and rheumatic infection. In spite of the fact that rheumatic infection in childhood created a form of sensitisation, a tide of immunity set in after a certain age, and possibly 30 per cent. of affected children recovered and acquired this immunity. The fact that the injuries inflicted conformed closely to a certain pattern was due rather to constancy on the part of extraneous influences than to the specificity of the streptococcus. The difference between the naturally acquired lesions in man and the lesions caused experimentally in animals was probably due to these extraneous influences. In a child the infection appeared to enter by a succession of small doses, perhaps through a mucous membrane, while in the animal, infection, perhaps enhanced by sojourn in the human body, was injected directly into the circulation. The latent chorea described by R. Miller, the granules found by V. Coates and Thomas, the pre-rheumatic state of which Vining has written, and the mitral stenosis only discovered in adult life were all explicable by the escape into the body of minute doses of bacteria.

Dr. RALPH STOCKMAN (professor of materia medica and therapeutics, University of Glasgow) dealt with the causation of fibrositis and panniculitis, which he described as really the sequelæ of various preceding diseases. He illustrated by lantern slides the gradual formation of a definite fibrous tissue from the loose soft texture with a sero-fibrinous matrix, resulting from the exudation of serum and proliferation of

fibroblasts, the common reaction to bacterial and chemical irritants. What happened in muscular rheumatism and panniculitis did not differ essentially from the histology of infected wounds with painful adhesions, thickened pleura, and cirrhosis of the liver. In fibrositis the irritant was most commonly a bacterial toxin produced on the site by a colony of microbes or possibly carried from a distance by the blood stream. Fibrositic patches might affect one area of the body only or be widespread, and in some localities took the form of pea-like masses with a core of inflamed fibrous tissue surrounded by fat. In the early stage these little swellings might disappear or be dispersed by massage. He regarded cold and wet as exacerbating factors of lesions already present rather than as causes of chronic rheumatism. He did not consider changes in the activity of the endocrine glands a cause of panniculitis. Increase in adiposity was apt to occur at the menopause and tension or pressure increased the sufferings of women who were already the subjects of subcutaneous fibrositis.

Dr. W. LANGDON BROWN (physician to St. Bartholomew's Hospital) dealt with the endocrine factor and thought we might confine our attention to the thyroid and ovaries. He agreed with the pioneer Hertoghe, whose recent death was a real loss to the profession, that it was most important to look for indications of hypothyroidism. He also agreed with Llewellyn that hyperthyroidism might be operative and that thyroid instability was the important thing. There might be a background of hypothyroidism with spurts of hyperthyroidism. Lack of iodine was a feature in both. Tonsillar sepsis was associated with thyroid derangement. Studies of the blood-sugar in rheumatism would throw light on the endocrine factor. The thyroid gland mobilises the sugar into the blood stream, whilst insulin leads to the storage of sugar as glycogen in the liver and muscles. Insulin might be useful for rheumatic hyperpyrexia. Thyroid inadequacy might be the inherited factor in rheumatism. Iodine was useful both for rheumatism and goitre. The thyroid and tonsils were only factors—not the whole story. The ovaries might have an effect at puberty and the menopause and act through the thyroid. The condition of the thyroid was the chief endocrine factor in rheumatism and rheumatoid affections.

Dr. GEOFFREY HADFIELD (demonstrator of pathology, University of Bristol) discussed the specificity of the tissue reactions in rheumatic diseases, and referred to the subcutaneous millet seed granules of Vincent Coates. These, he said, were composed of proliferating reticulo-endothelium, were rich in newly formed capillaries, and presented similarity to what was supposed to be the primary tissue reaction in the infective arthritic group. The granules were the classical nodules in miniature. This reaction, while not so spectacular as the giant-cell system of tubercle, was as constant as that of gumma formation. There was little difference between the early skin nodule of infective arthritis and the submiliary myocardial nodule of acute rheumatism. In panniculitis the reaction was not exclusively confined to the local reticulo-endothelium, as in acute rheumatism and infective arthritis, and this dissimilarity indicated a more virulent infection or a lessened local immunity in panniculitis. Much more work was needed, but up to now the infection of chronic infective arthritis appeared to be one by a saprophytic streptococcus to which the patient had a high degree of general immunity but a low degree of local immunity in the synovia of his joints.

Dr. P. LAZARUS-BARLOW described work which he had done with Small's streptococcus cardio-arthritidis.

Prof. ISIDORE GUNZBURG (Medical Director) laid emphasis on the bad state of the skin as a causative factor.

Prof. TOM HARE (Royal Veterinary College) described the types of rheumatic disease prevalent in animals and the research work as to ætiology in progress. In horses and dogs we had rheumatic disease, the natural course of which is within the experimental period and which can be terminated at any stage at the will of the investigator. The investigation of this disease in its pathogenic phases offered great possibilities of advancing our knowledge of rheumatic disease in man.

Dr. L. BERTRAND (Antwerp) described work done with a polymorphic anaerobic organism discovered 30 years ago, which sometimes took the diplococcal form. If the proper technique was employed it was to be found in rheumatic lesions, and its changes under culture perhaps accounted for its varying effects on human tissue. A vaccine made from it was efficacious.

Dr. R. WATERHOUSE (Bath) thought rheumatoid arthritis and osteo-arthritis had little in common. Heberden's nodes were found more in the well-to-do than in the poor.

Dr. J. B. BURT (Buxton) believed the investigation of arthritis in animals would be helpful. One in 5 cab horses had arthritis. Trauma alone would cause it; the position of osteophytes was determined by strain and heredity—e.g., a short pastern, had its effect.

Surgeon Vice-Admiral GASKELL, R.N., said acute rheumatism was now very rare in the navy. There had also been a decline in chronic rheumatism, but they had not yet found any lessening of the prevalence of heart disease of rheumatic origin.

Dr. F. G. THOMSON (Bath) showed that Graves' disease and infective arthritis had a similar age curve, chiefly from 16 to 40 years. Chronic villous arthritis of the menopause was always associated with thyroid deficiency.

Dr. WATSON-WILLIAMS (Bristol) thought endocrine imbalance was the result and not the cause of these chronic infections.

Dr. G. L. KERR PRINGLE (Harrogate) said the atrophic type of rheumatoid arthritis only occurred in females. It might be associated with the beginning of menstruation. Pregnancy relieved it, but it returned at the puerperium. It began in the small joints, was centripetal and symmetrical. Diathermy of the ovaries probably removed the endocrine imbalance.

Dr. HENRY ELLIS (London) stressed the importance of biochemistry and the acid-base equilibrium of the urine. Endocrine rheumatism caused no alteration in this equilibrium. The cases with excess of uric acid were a special type. The alkaline and acid types were hereditary and needed different treatment.

Dr. A. P. CAWADIAS (London) referred to the sulphur metabolism in arthritis deformans—i.e., rheumatoid arthritis—and said more study of the metabolic changes was needed.

Dr. F. B. S. HOLMES (Bury) referred to 50 cases of afebrile chronic arthritis, all able to stand upright in whom the basal metabolism was normal. Nevertheless we knew that thyroid benefited such cases.

Prof. PISANI (Florence) referred to acute rheumatism as a germ disease and to chronic forms as largely due to endocrine and sympathetic disturbances and anaphylaxis.

Dr. LANGDON BROWN, in replying upon the discussion, insisted that there must be no undue stressing of the endocrine and metabolic factors and that the infective theory still ranks high.

Communications, which will be published with the proceedings, were also submitted by authors unable to be present—viz., by Dr. GUNNAR KAHLMETER (Stockholm) on the prognostic value of the rate of sedimentation of the erythrocytes; by Prof. H. STRAUSS (Berlin) to the effect that endocrine factors are not truly causal; by Dr. HOMER SWIFT (New York) on rheumatic fever as a manifestation of hypersensitiveness to streptococci; by Dr. RALPH PEMBERTON (Philadelphia) on stasis of the capillary circulation and delayed sugar removal; by Dr. J. GORDON WATSON (Bath) on the hepatic and pancreatic functions in chronic rheumatic diseases; and by Mr. A. G. TIMBRELL FISHER (London) on the pathology of chronic arthritis with special reference to osteo-arthritis.

To this Session of the Conference there was also communicated an interesting paper dealing with

eumatic fever, viewed as essentially a cardiac oblem, contributed by Dr. Weil, of Paris, and Dr. Bezançon, which is published in another column.

THIRD SESSION—TREATMENT.

The Third Session commenced punctually at o'clock with brief introductory words from r FARQUHAR BUZZARD, who called upon

Dr. R. L. J. LLEWELLYN (Member of the Committee the Medical Research Council on Chronic Rheuatism) to read his paper on Prevention. Dr. lewellyn related the classification of rheumatic seases adopted by the Ministry of Health, which, ith other considerations, he thought supplied a good asis for provisional working, though a change in ttitude was required in respect of treatment; there ould be less dwelling on "end-results" and more ress laid on "beginnings." He insisted on the nportance of considering rheumatic diseases from the hysiological standpoint, and advocated investigation abnormalities in sweat secretion, believing that the aintenance of the skin in its functional efficiency was essential importance. In this connexion he urged rly resort to spa treatment, as detoxication could us be effected and the blood-supply of the skin d the sweat secretion could be stabilised.

Dr. F. J. POYNTON (physician to University College ospital) gave his reasons for thinking that salicylate soda is not a specific for acute rheumatism in ildhood in the same sense that quinine is for malaria; though it relieved the joint pains it did not seem to fluence the subcutaneous nodules or to benefit e heart. Further, he thought its use, if pushed, was stinctly dangerous, especially in fragile children with vere carditis. The dangers which he feared, and hich he attributed to the drug rather than to the ness, were death from coma or excessive vomiting, tense depression, pronounced cardiac weakness, and ossibly œdema of the lungs. He had now used tolysin" for four years and had found it to be a fe drug, even in cases of severe pancarditis, and with action comparable to that of the salicylates on eumatic symptoms. He usually gave from 30 to grains in the 24 hours to young children. Dr. Poynton mmunicated notes of cases illustrating the effect of lysin.

Dr. A. P. THOMSON (physician to the Children's ospital, Birmingham) gave the requirements of the dinary rheumatic child as: (1) hospital treatment in e acute stage, for perhaps six weeks; (2) treatment in convalescent home, mostly at rest in bed, for a eriod varying from 1 to 6 months; (3) treatment in institution hospital in which the child's return activity is regulated under careful supervision. askerville School, in the suburbs of Birmingham, as such an institution and 7 years' experience of it d convinced him of its value and shown that the verage case needed a stay of 9 months. The eatment of rheumatism must not be cut off from e hospitals and the school of recovery could be ked up, as had been done in Birmingham, by having common medical staff. Baskerville was a "special ducation" school and education was helpful to eatment. Support from the public funds was needed r the establishment of such institutions throughout e country. Dr. Thomson described details of anagement and showed lantern slides of the school work.

Sir WILLIAM WILLCOX (physician to St. Mary's ospital) read a communication on the treatment of nderlying infection in all the diseases comprised by e terms: (1) acute and subacute rheumatism: and) infective rheumatism, the latter term covering acute fective arthritis, fibrositis, and chronic arthritis. e analysed the arguments for the various directions treatment, and in discussing special biological easures issued a grave warning against the abuse vaccine therapy although pointing out the value of accines when properly administered. He concluded y noting that vaccines can with advantage be mbined with other methods of treatment.

Dr. J. CAMPBELL MCCLURE (physician to the French Hospital) spoke as one not now engaged in supervising physical treatment but rather as one who saw many cases before and after physical treatment. The best results, he said, were obtained by a combination of methods, and the choice of the proper combination was no easy matter and demanded an intimate knowledge of the conditions underlying the lesions treated and a very practical knowledge of the best methods of physiotherapy. Physical methods were of great value and disbelief in their efficacy had been caused by unskilful application and unwise prescription. For example, massage might be too rough or baths might be too hot, and he had known an obstinate mucous colitis caused by a badly administered Plombières douche in combination with an excessive diet of lactic oats. The attendants needed to be well trained and well directed.

Prof. ISIDORE GUNZBURG described the anti-rheumatic centre established in connexion with the University of Brussels, with its very complete equipment for treatment, consultation, and research, and gave a sketch of the encouraging results obtained although most of the patients came for treatment very late. At the beginning of such a scheme it was perhaps natural that the severest and oldest cases were the first comers. A referendum indicated, he said, that the patients who have ceased to attend have derived considerable benefit. A detailed description of the Antwerp scheme was given in the hope that it would stimulate the creation of centres in all countries and thus help on the international struggle against rheumatism.

Dr. B. WHITCHURCH HOWELL (London) referred to the use of traction and immobilisation and operative procedures for securing stiff painless joints and new joints with a limited mobility, and illustrated his remarks by photographs. For spondylitis rest in the prone position was imperative and manipulation must only be undertaken in the chronic stage, after X ray examination and the certainty that there were no loose osteophytes. Much relief could be given by surgery.

Dr. H. WARREN CROWE (London) believed that vaccines were not more used on account of faulty technique. Some got no result because the dose was too small; others a bad result because the dose was too big. The first principle was to begin with a very small dose; streptococci which were the easiest to grow were often non-pathogenic and the vaccines made from them might be quite inert. Staphylococci were quite as important as streptococci in chronic rheumatic diseases and a focal joint reaction with a staphylococcus should be regarded as specifically incriminating that organism.

Dr. C. W. BUCKLEY (Buxton) said there should be facilities at spas to enable general practitioners to learn about the treatment done.

Dr. VINCENT COATES (hon. medical secretary to the Conference) said obvious foci must be removed, but the systemic nature of the disease must not be lost sight of. The essentials of treatment were the raising of immunity and the correction of biochemical abnormalities. Fractional test-meals, the careful examination of the stools, and the estimation of the blood gave indications for the treatment of achlorhydria, secondary anæmia, and leucopenia, and for the selection of a suitable diet. Joints were too much manipulated; they required splinting in the acute stage. Hydrotherapy was always useful and mud baths were sometimes so.

Dr. A. P. CAWADIAS (London) said that endocrines had a limited use in treatment. He had found colloidal sulphur useful. Auto-vaccines were no better than stock vaccines and all vaccine treatment was shock therapy. Arthritis deformans was not due to one cause but to a conjunction of causes.

Dr. HANS JANSEN (Copenhagen) outlined the forms and combinations of physical treatment which he advocated for the various types of chronic rheumatism.

Dr. DONALD BRIMS (London) explained the technique which he employed for the subdermal injection of oxygen, the application to the skin of emanations of radium and thorium, and the intradermal use of a new entero-antigen, with the protein and microbes removed, consisting only of lipoids and amino-acids. He claimed "amazingly good" results from this treatment in Paris, London, and Croydon.

Dr. WATSON-WILLIAMS (Bristol) described an unusual case where the focus had been postnasal catarrh and advocated a very careful search for foci before having the teeth out. Care was needed to see that only a subsidiary focus had been removed. He thought vaccine treatment was mostly shock therapy.

THE SOCIAL SIDE.

The City of Bath and the local branch of the British Medical Association received the members of the Conference with profuse hospitality. The City had arranged rooms at the various hotels for their numerous guests, while members of the medical profession at Bath showed the same hospitality. The whole organisation of the Baths was placed freely at the disposal of the visitors, and the Pump Room, built round the famous Roman bath, provided, as on many previous occasions, a model centre for the comfortable entertainment of a crowd of guests.

On Thursday evening a dinner was given by the City over which the Deputy Mayor and the Mayoress of Bath presided, and at which all the company had the pleasure of listening to excellent speeches from Sir GEORGE NEWMAN, in returning thanks for the guests and delegates, and from Lord DAWSON, who described the beauties of Bath with real eloquence. Upon this there followed a reception by the Lady Mayoress, and later various entertainments were given, at the close of which many members of the Conference, and not only the youngest among them, proceeded to dance enthusiastically till a late hour.

On Friday the Bath Branch of the British Medical Association were the hosts of the Conference at lunch at the Grand Pump Room Hotel, when Dr. R. G. GORDON, President of the Branch, presided and indicated in his speech of welcome how deeply the Association had at heart such great social medical questions as the incidence of rheumatic diseases. Sir FARQUHAR BUZZARD having replied for the guests, Sir HUMPHRY ROLLESTON proposed the health of Dr. F. G. Thomson, the Chairman of the Conference, after whose reply Dr. GUNZBURG set out the pleasure which the visit had given to himself and all his confrères.

The annual meeting of the Balneological Section of the Royal Society of Medicine was held on Saturday, May 12th, following the Conference, and in connexion with it demonstrations of treatment on appropriate cases were given at the Hot Mineral Baths throughout the early morning. Clinical cases were demonstrated later at the Royal Mineral Water Hospital by Dr. R. Waterhouse (osteo-arthritis), Dr. J. Lindsay (gout), Dr. Vincent Coates (infective arthritis), Dr. R. G. Gordon (fibrositis), and Dr. A. Gordon Watson (sciatica). In the afternoon a motor tour gave the guests an opportunity of seeing Bath thoroughly, its environment, and its historic features. On Sunday there was a service at the Abbey at 11, to which delegates were bidden, and in the afternoon a motor tour of the Mendips was arranged, giving the visitors the chance of seeing the famous Cheddar Gorge.

FRANCES WOOD MEMORIAL PRIZE.—This year the Council of the Royal Statistical Society will again award this prize, of the value of £30, for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the wage-earning classes. Essays should be sent not later than Oct. 31st to the hon. secretaries of the Royal Statistical Society, at 9, Adelphi-terrace, London, W.C. 2, from whom particulars may be had as to eligibility to compete.

Reviews and Notices of Books.

THE BLOOD-VESSELS OF THE HUMAN SKIN AND THEIR RESPONSES.

By THOMAS LEWIS, M.D., F.R.S., Physician of the Staff of the Medical Research Council; Physician of University College Hospital. London: Shaw and Sons, Ltd. 1927. With 76 figures. Pp. 332. 37*s.* 6*d.*

Harvey raised at least as many problems as he solved in the discovery which we celebrate this week. It is appropriate to draw attention to some of the recent efforts made by a physician-physiologist, whose life-work has been the study of the circulatory mechanism, to throw light on the control of the circulation in the organ most distal from the heart. Much of the work published by Sir Thomas Lewis in this monograph has been carried on with his collaborators over a period of 11 years, and has already appeared in original articles in *Heart* and in the *Journal of Physiology*. These the author has collected not merely with the idea of presenting his observations in a more readable form, but with the purpose of stimulating a wider study and teaching of human physiology.

The ultimate object of his researches is to examine more accurately the various ways in which the blood flow to the skin is controlled, and to account more fully for variations in cutaneous colour. In the introductory chapter, therefore, he gives an account based on the work of Spalteholz, of the anatomy of the blood-vessels of the skin, and describes in detail the methods employed in examining those vessels microscopically, and in studying by means of thermo-electric couples skin temperature and its change in response to various influences. Apart from this, his apparatus and technique are of the simplest order. With keen observation and great ingenuity in constructing experiments, he has studied the pallor of the skin produced, after a latent period by a slight mechanical stimulus, and has proved conclusively that it is due to actual contraction of the minute vessels in response to tension of their walls. He further brings out the surprising fact that the force exerted by these terminal arterioles, capillaries, and small venules is at least equal to, if it does not exceed, any pressure which can be brought to bear on them from the arterial side. If a greater stimulus is applied to the skin, a red instead of a white reaction is produced, due to active dilatation of the minute vessels, and this appears without the intervention of the central nervous system or of a local nervous reflex. Only if the skin is susceptible or the stroke stimulus unusually strong, does there appear surrounding the red line a spreading flush or "flare," the result of dilatation of the strong muscular arterioles by a local axon-reflex. This leads him to the central theme of his monograph, the "triple response" of the skin to injury. The response consists of localised capillary dilatation, the coincident local œdema or wheal which succeeds it, and the surrounding "flare." Whether the injury be mechanical, electrical, chemical, or thermal, the triple vascular reaction is essentially the same. Sir Thomas Lewis examines the factors responsible for the production of the three phases of this complex response, and presents a considerable amount of evidence to show that injury of the skin liberates a substance exerting a local action indistinguishable from that of histamine, on the cutaneous vessels and nerves. He is unable to prove conclusively that it is histamine, and wisely refers to it as the "H-substance." The idea that tissue destruction leads to the production of a histamine-like body is, of course, not novel, for the work of H. H. Dale, W. B. Cannon, and many others has shown that there is a remarkable similarity between wound-shock and the shock resulting from the intravenous injection of histamine. But the fact that the simple response of a healthy human skin to trivial injuries is of a simi-

ıture, though varying in degree, to that following ave destruction of tissue, is of the greatest interest, that it would appear to be the unvarying reply of e cell to injury of any kind. Certain difficulties e inherent in this conception, particularly with gard to slowly acting stimuli such as ultra-violet ght, X rays, radium, bacterial poisons, and certain in irritants such as mustard gas, cantharidin, and loroform. The reaction produced by these irritants latent, taking anything from several hours to several eeks to develop, and it is not very clear at first ght how this could be the result of liberation of the -substance. Sir Thomas Lewis recognises the fficulty, but adduces evidence in support of the view at the fundamental changes are essentially the same in the case of the rapidly acting irritants. The apter on the regulation of blood flow by central rvous channels is arresting in the explanation offered the vaso-dilatation following stimulation of a nsory nerve, which was noted by S. Stricker and nfirmed by W. Bayliss and J. N. Langley. It has en deduced from this phenomenon that vaso-lator fibres accompany the sensory nerves, and that e impulse is carried in the latter antidromically. r Thomas Lewis, however, holds the view, strongly pported by the evidence available, that the anti-omic nerve impulse influences metabolism in the lls of the skin, and releases in the tissue spaces the -substance, which thus indirectly produces vaso-latation. He believes that herpes zoster and rpetiform eruptions are produced by a similar echanism.

These are only a few of the points of interest in this onograph. The physician and surgeon, as well as e physiologist, will find material for reflection and imulation in the observations and experiments on active hyperæmia, skin colour, capillary pulsation, ier's spots, and the development and distribution of orbid skin eruptions. Whether or not the author cceeds in stimulating the study and teaching of man physiology, his observations will certainly ove the basis for investigation in the field of prac-cal medicine, and may indeed play a considerable rt in the development of clinical knowledge of seases of the circulation and of the skin. The bt which clinical medicine already owes to Sir homas Lewis for advancing our understanding of sorders of the action of the heart is great; the inical scope of his present line of work is no less wide.

HE MEDICAL ANNUAL, 1928.

Forty-sixth year. Bristol: John Wright and Sons, Ltd; London: Simpkin, Marshall, Ltd. Pp. 632. 20*s*.

'Année Médicale Pratique, 1928. Seventh year. Edited by Dr. CAMILLE LIAN, Professeur Agrégé à la Faculté; Médecin de l'Hôpital Tenon. Paris: René Lépine. Pp. 652.

THE function of a medical annual is to provide aders who have not been able to keep in full touch ith current medical literature with an accessible view of all important events of the preceding ear. The "Medical Annual" maintains its high andard of excellence, in subject matter and in the earness with which that matter is arranged and dexed. The most important feature is the Dictionary Practical Medicine, which embodies abstracts the most valuable recent papers on treatment. he editors naturally give first place this year to ver treatment of pernicious anæmia, the two articles ı which, by Prof. F. R. Fraser and Dr. I. J. Davies, rm as compact and comprehensive an essay on the bject as any practitioner could wish for. Dr. enry Devine describes narcosan, a new remedy for cohol and drug addiction, which consists of a ixture of vegetable lipoids and vitamins and has ven promising results; Dr. Davies contributes review of the present position of knowledge about e vitamins. On the surgical side comment is ade on the use of large doses of anti-gas gangrene serum against appendicitis with peritonitis and in intestinal obstruction, on the assumption that these complaints are due to the action of *B. welchii*. A successful case of ligature of the abdominal aorta is recorded, and an article by Sir William Wheeler describes the operation of division of the scalenus anticus muscle to relieve pressure on the brachial plexus by cervical rib. A section on the surgical diseases of children has been introduced, and deals, among other subjects, with a new inflation treatment without operation for intussusception, and with some claims made by South American surgeons for extraordinarily quick cures in bone tuberculosis. Besides the index, the Annual also contains descriptions of new pharmaceutical and dietetic products, instruments, and appliances, plentifully illustrated; a classified list of books on medical subjects published last year, and the usual gazetteer of mental institutions, spas, and periodicals. It is a reference book used and valued by medical men in every part of the Empire.

"L'Année Médicale Pratique" is a Frencn attempt to meet the same need. It was to have appeared first in the autumn of 1914, but was delayed by the war until 1922. It contains a digest of recent medical work in all languages, together with miscellaneous information, and improves every year. Its scope is not yet as wide as that of the older publication, but since the outlook of its editor has a different focus, the British reader will find much to interest him in its pages.

DIFFERENTIAL DIAGNOSIS IN NEUROLOGY.

Praktische Differentialdiagnostik für Ärzte und Studierende. Edited by Prof. Dr. G. HONIGMANN, Giessen. Bd. II. Neurologie. Teil 2. Psychoneurosen, Funktionelle Neurosen, Erschöpfungszustände. By Dr. W. UNGER, Superintendent of the Hohenpeissenberg Sanatorium. Dresden and Leipzig: Theodor Steinkopff. 1927. Pp. 161–300. R.M.8.

THIS instalment of the large vade-mecum of differential diagnosis for practitioners, edited by Prof. Honigmann, contains sections dealing with neuroses of all kinds, ranging from conditions of fatigue and constitutional neuropathic states to migraine, epilepsy, and affections of the sympathetic nervous system. A useful division of the book examines the diagnostic significance of a number of syndromes and symptoms, such as headache, disorders of sleep, fits and attacks of various kinds, "weakness," and sexual impairment. As befits a text-book of this kind, the descriptions are brief (in some instances almost to sketchiness), succinct, and eminently practical.

A FRENCH TUBERCULOSIS VADE-MECUM.

Tuberculose pulmonaire, Tuberculose des séreuses. By Dr. PIERRE PRUVOST. Paris: Librairie Octave Doin. 1927. Pp. 448. Fr.30.

THIS book is a squat little volume in a series of Daily Consultations, evidently intended for carrying in the pocket or handbag of the busy general practitioner. It is divided up into small sections and paragraphs with headings in black type heavily underlined, and italics are freely used throughout for purposes of emphasis. There is hardly a redundant word in the book; everything, including the illustrations, appears to have been sacrificed to the multum-in-parvo ideal. The illustrations are in some cases ingeniously devised to show all that is essential at a glance, but much has been sacrificed to the odd format. Prescriptions are fairly numerous; there is a short chapter illustrating graphic representation of physical signs, and a list of hospitals, sanatoria (public and private), preventoria, schools, and isolation institutions to which the French practitioner may send his patients. The information on the clinical side is succinct and pithy, but the pathological teaching is meagre.

MINOR SURGERY AND BANDAGING.

Nineteenth edition. By GWYNNE WILLIAMS, M.S., F.R.C.S., University College Hospital. London: J. and A. Churchill. 1927. Pp. 424. 10s.

THIS handbook has reached such an established position that comment is scarcely necessary, but we must congratulate its author on the way in which he has brought it up to date and yet kept it within its original convenient compass. The house surgeon can turn to it for the latest hints on the putting-up of a fractured femur or the treatment of a burn, and if he has progressive ideas he will be delighted to find a brief, but useful, account of the methods of local anæsthesia. We cannot imagine a handbook of greater use to the embryo surgeon, and there are few who practise that art who would not get valuable hints from its pages.

JOURNALS.

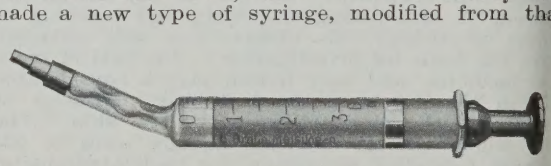
AMERICAN REVIEW OF TUBERCULOSIS. March, 1928. Vol. XVII., No. 3.—Dr. Henry Willis reports the result of experiments carried out on guinea-pigs to determine the duration of cutaneous hypersensitiveness to tuberculin following inoculations with bacilli of low virulence, and to investigate the relation of tuberculo-immunity to tuberculo-allergy. A group of guinea-pigs was submitted to subcutaneous inoculation with an emulsion of tubercle bacilli. At the end of a year the animals were all found to be healthy and for the purposes of the experiment were regarded as "immunes," a number of non-infected controls being reserved as "non-immunes." Observations were made on the result of cutaneous tests carried out at intervals beginning at the twelfth and terminating at the thirtieth month after the original inoculations. Further experiments were made to determine the degree of immunity persisting to the end of the period of the experiment. The results support the view that allergy fluctuates with the course of infection and that as infection subsides allergy diminishes. Two years after infection allergy could not be demonstrated by an injection double that of the ordinary reacting dose of antigen. Nevertheless, that some degree of allergy may persist for an even longer period was shown by evidence of hypersensitiveness, which was revealed by a dose of five times the normal standard given 27 months after the original infection. Dr. Willis found that a high degree of immunity might accompany a degree of allergy barely demonstrable. A new infection with a virulent strain of bacilli was capable, however, of restoring allergy at once to a high level. Thus an allergy which has become "latent" may be quickly revived in response to infection. It is possible, therefore, that immunity may also become "latent" and be capable of revival in a similar manner, both allergy and immunity responding to the same stimulus in the same way.—Dr. Casper F. Hegner, in a paper on Surgical Rest in Pulmonary Tuberculosis, summarises the means at our disposal to secure this, and outlines the indications for their use. Phrenic avulsion, extra- and intra-pleural pneumolysis, limited and complete thoracoplasty are briefly described. Dr. Hegner gives a warning that to be of value in pulmonary tuberculosis the aid of surgery must be invoked before the patient's reserve is depleted. Phrenic avulsion is recommended as a valuable adjunct to induced pneumothorax. Stasis of blood and lymph within the lung and paralysis of the diaphragm cause a restriction of gas-absorption from the pleural space and the necessity for refills is thus less frequent. Phrenic avulsion by lessening the work of one lung throws an added strain on its fellow. When thoracoplasty or other surgical procedure is under consideration and a doubt exists as to the condition of the opposite lung, phrenic avulsion, carried out on the extensively diseased side, may thus be used to test the capacity of the other lung to sustain respiration. Intrapleural pneumolysis by the method of Jacobaeus entails grave risks from hæmorrhage, empyema, and the bronchial or pleural fistula, and is not recommended. Dr. Hegner usually employs local anæsthesia when operating for thoracoplasty. With this method the condition of the patient can be better gauged during operation, the cough reflex is not inhibited, aspiration of secretion is avoided, there is less oozing of blood and the immediate post-operative phase is much better.—A contribution on the behaviour of white blood cells in tuberculosis was summarised last week on p. 976.

FUKUOKA ACTA MEDICA.—The issue of January, 1928, the first of Vol. XXI., contains the conclusion of Dr. H. Kokawa's work on experimental trypanosomiasis with special reference to the mechanism of trypanolysis. Dr. R. Hattori continues his study of the blood picture in artificial malaria and makes some observations on the occurrence of spirochætes in progressive paralysis. The other articles are from the pens of S. Ohmori on certain interesting anatomical points in the bird's heart; H. Tsunoda on the causes of the rise of venous pressure in pneumothorax, and J. Uegaki on a hæmo-proteus occurring in Formosa. While the journal is printed in Japanese characters, précis of the papers appear in German, French, or English as the case may be.

New Inventions.

AN IMPROVED SYRINGE FOR THE TREATMENT OF VARICOSE VEINS.

AFTER 75 years of varying fortunes, the successful treatment of varicose veins by the injection of sclerosing media is now receiving the recognition it deserves. There is still room for improvement in the instruments used, and we have recently had made a new type of syringe, modified from that



invented by Katz, which appears after a test period of three months to possess definite advantages over the Record syringe hitherto recommended. As will be seen from the accompanying illustration, this syringe has a glass barrel and piston, the former graduated in capacities of one quarter of a cubic centimetre, the latter coloured dark blue (in the actual syringe) for convenience in gauging the amount of a colourless fluid which is to be injected. The lower end of the barrel passes into a fine glass capillary containing two small dilated chambers and bent upon itself so as not to obstruct from view the segment of the vein to be injected. A white, opaque background has been introduced in the length of this tube in order to render the appearance of a minute column of blood more easily visible. The metal nozzle of the syringe, which snugly fits all makes of hypodermic needles, has the same coefficient of expansion as glass, thus readily allowing of sterilisation by boiling. When a vein is entered, blood can be aspirated along the capillary tube into the ampullæ, and when, subsequently, an injection is made, the blood is forced back into the vein, leaving the remaining fluid in the barrel clear and untinged. In this way it is possible to administer to a patient six or more injections without having to change or wash out the syringe.

The instrument is manufactured by Messrs. B. Braun and Co., Ltd., Melsungen, Germany, the makers of the original Katz vein syringe. The English agents are Messrs. Adair, Dutt and Co., 47, Victoria-street, London, S.W. 1.

THE LANCET.

LONDON: SATURDAY, MAY 19, 1928.

WILLIAM HARVEY.

THE third centenary of the publication of WILLIAM HARVEY'S "De Motu Cordis" has been celebrated ring the week with ceremony befitting a discovery ich first made rational treatment of human disease ssible. The KING received at Buckingham Palace) delegates representing 28 countries who presented address of homage to the memory of this English- n of science; but to realise his greatness it is essary for the student of medicine to live back o the circumstances of HARVEY'S time. Amid all pomp and circumstance of Monday's pageant let one forget the little dark studious physician who at a table in the Great Hall of St. Bartholomew's spital, writing prescriptions for such patients as uld be brought to him, with the hospital apothecary l matron standing one on each side of his chair. was in these surroundings that HARVEY developed courage of which so many have spoken, a rage which we witness in his standing up against surgeons of his own hospital, in his insistence that h should tell "what he findeth and what he useth every external malady, that so the doctor being ormed may better with judgement order his scriptions." Against this, as NORMAN MOORE has ted, the chirurgeons vigorously protested. HARVEY'S rage did not excite among his contemporaries attention which it deserved, for although his set of the Galenic systemic of the circulation ranks h GALILEO'S upset of the Copernican system of the ternal universe, it did not bring him into conflict h the orthodox religious teaching of his time and was not HARVEY who, murmuring "but it does ve," left the presence of a persecuting Inquisitor. r all that, the detachment which enabled him to strike t from tradition, to discard the teachings of GALEN, ich were then accepted and revered as those of a phet, was courage of no common order. It is, Sir ARTHUR KEITH reminds us, difficult for us derns to visualise the circulation of pre-Harveian nes, when under the physician's finger the artery panded of itself, drawing in blood, spirits, air, and pours of all sorts and squeezing them out again as contracted. Generations of students, brought up on lucid diagram in HUXLEY'S "Elementary Physio- y," will have difficulty in facing the problems of circulation as HARVEY faced them. His discovery me to him with no flash of light, with no startling ributes of a revelation. It was an answer to a ies of logical questions which he put to himself, ich led up to the observation: "I began to think ether there might not be a motion, as it were, in a cle." It was the result, as he says, of demonstra- ns before his colleagues at his College, demonstra- ns repeated again and again until every objection s met and dealt with. It is doubtful if any neration has visualised these crucial experiments in e way that has been made possible by the pictorial n prepared by Sir THOMAS LEWIS and Dr. DALE, a monstration which won the admiration of all those o witnessed it.

Many discoveries have resembled the sudden crystal- ation of an over-saturated solution when a crystal dropped into it; there have been other investigators the point of reaching the same goal at the same time. But HARVEY was far ahead of his fellow workers, both in experiment and interpretation of results. The great VESALIUS, although he could find no holes in the ventricular septum, assumed the passage of humours through it. HARVEY avowed himself a partisan of truth alone, and was so sure of himself and of his observations that he spent no time in controversy, or in refuting the arguments of others. Indeed, as Mr. GEOFFREY KEYNES tells us in the preface to the admirable bibliography which appears for the occasion,[1] HARVEY published only three books during his life, so that the task of compilation has been a simple one. HARVEY'S critics, though vociferous enough in their day, have mostly sunk into an oblivion in which they may be allowed to remain; but no one who wishes to understand the circulation of the blood can safely refrain from reading of its discovery in one or other of the places indicated in the bibliography.

THE BORDERLAND OF PHYSIOLOGY AND PSYCHOLOGY.

MODERN histological methods have taught us much about the structure of the cerebral cortex, but its function has been more difficult to investigate. It forms the borderland between psychology and physiology, and explorers from these two sciences do not yet report their discoveries in a common language. The behaviour of a spinal animal is complex enough, as SHERRINGTON and others have shown, but at least its response to stimuli is uniform and quantitative; whereas the higher reflexes are controlled by rules so obscure that the general impression has been one of anarchy. For a workable method of observing these higher reflexes in animals we are indebted to the school of Prof. IVAN PAVLOV, who gave an account of his most recent work in the Croonian Lecture of the Royal Society, of which we published a summary last week. His invaluable experiments show that the difficulty of prophesying the results of stimulation of the cortex is due less to the complexity of the reflexes than to the great variety of influences which may inhibit response.

The first step in the comprehension of PAVLOV'S work is to realise the distinction between inborn reflexes, characteristic of any species, and acquired reflexes, which are peculiar to the individual and are founded on his own experience. PAVLOV classes the first group as "unconditioned" reflexes, whilst the second are called "conditioned" reflexes, because their nature largely depends upon the conditions under which they are established. Examples of inborn or unconditioned reflexes are the knee-jerk, the stepping reflex, the lower sexual reflex, and salivation at the sight of food. Advantage was taken of this last phenomenon in PAVLOV'S investigations in the dog. He found that if a musical note is regularly sounded at the time when food is presented, salivation is eventually stimulated by the sound alone, in the absence of any food. This is a conditioned reflex since it depends on the special experience acquired by the individual. Such a reflex may be provoked by any form of stimulus—auditory, visual, cutaneous, or olfactory—but it must of course develop out of a reflex mechanism which is already in existence. Furthermore, the time-element is of importance—for example, if in the salivation experiment food were given before the sound, it is obvious that no association would

[1] Bibliography of the Writings of William Harvey. Cambridge University Press. Pp. 67. 21s.

be set up. The underlying principle of the formation of new reflexes is that if during the occurrence of any unconditioned reflex a receptor organ is stimulated, a new path is formed between the receptor and the effector organ. A given stimulus may thus acquire, for the individual in question, a significance which it did not formerly possess; by taking over the mechanism of the unconditioned reflex on which it was based it produces results which may appear irrelevant.

These studies are purely objective. The secretion of saliva, the chief indicator used in the experiments, is particularly suited to such objectivity, and other indicators are similarly treated. The experimental dog cannot be usefully interrogated about his mental experiences, and deductions are avoided as to the presence of sensations or emotions, a knowledge of which rests upon our own introspective observations. The turning of the head in a specific direction is only a turning of the head; no presumption as to awareness is made, for awareness is at present outside the bounds of an objective physiology. By this self-imposed limitation the physiologist provides the psychologist with a means of making comprehensible the fact that stimuli can fall upon a peripheral receptor organ, be analysed by the cortical part of the system, and produce a complex result without the subject being aware of the process of analysis or perhaps even of the stimulus, which has been conditioned by previous experience. It is a commonplace of psycho-pathology that mal-adaptive mechanisms can be brought into play by stimuli that are not perceived by the subject or, if they are perceived, are not consciously brought into relation with the previous conditioning experience. Some phobias arise in this way, and in answer to ordinary questioning the patient is able to throw no more light upon the cortical processes at work than is Prof. PAVLOV'S experimental dog. What is not so generally known, however, is that the symptom may show itself at the physiological level, and there have been described cardiac and asthmatic attacks, or recurrent intestinal disturbances, arising from earlier experiences that have conditioned a complicated reaction derived from a simple inborn reflex. In the human subject it is possible to elucidate these earlier experiences by modern psychological technique and thus study the subjective aspect of conditions that are being simultaneously approached by the objective physiological methods of PAVLOV and of ANREP, his pupil and interpreter. Such a combined attack upon clinical problems may lead to the discovery of a relation between superficially incompatible views. The allergen theory of asthma, for example, appears irreconcilable with that of a psychogenic origin, and yet there is clinical evidence in favour of each of these theories. Given a primary emotional stimulus that produces asthma in the presence of a possible allergic substance, that substance may produce a conditioned reflex and come to be a sufficient stimulus to provoke the exaggerated dyspnœic reaction originally roused by the emotional stimulus. The labile skin reactions known to occur during an asthmatic attack may indicate a physical disposition towards the development of a conditioned reflex dependent upon a chance allergen. This would account for the capriciousness of allergic phenomena, which is otherwise so difficult to bring under any known physiological law. That a consideration of PAVLOV'S work should arouse a suggestion of this kind indicates the prospect that a further connecting link between physiological and psychological medicine is being forged.

THE RHEUMATIC DISEASES.

THE Conference on Rheumatic Diseases at Bath was a genuine success, regarded from every point of view. The medical profession of the city and the civic authorities are alike to be congratulated upon having taken the lead of a great and orderly endeavour to mitigate the evils of a scourge upon our public and our individual health, and so much interest has been aroused by many of the contributions to the debates that we may look forward confidently to this translation into practical form of some of the advice given.

The proceedings of the Conference were arranged in a sequence which indicated exactly the extent of the evils to be counteracted and the multiplicity of forms in which those evils manifest themselves, calling accordingly for prevention and relief in an embarrassing variety of directions. At the first session the speakers presented authoritative descriptions of the social aspect of rheumatic diseases, of their cost to the country, and of the existing methods for organised defence; the general incidence of rheumatic diseases and the influence upon this incidence of the circumstances of environment were debated in such communications as those made by Sir WALTER KINNEAR, the Controller of the Insurance Department of the Ministry of Health, and Dr. REGINALD MILLER, which are published in full in other pages of this issue of THE LANCET. At the second Session of the Conference we obtained an illuminating impression of the vast work that lies ahead before any definite opinions can be arrived at in regard to the comparative importance of the many factors playing their part in ætiology. There were detailed the predisposing circumstances in the rheumatic inflammation of childhood and the possible bacterial association therewith; the position in any orderly scheme of causation occupied by cardiac symptoms; and the reasons for remembering the endocrine influences that might be at work. Further, the pathology of chronic arthritis and fibrositis was reviewed, and especially interesting communications were made in regard to the manifestations of infective arthritis in animals. The contributions were made in almost every case with a sense real of responsibility, the evidence preceding the conclusions.

The manner in which the proceedings were conducted is especially to be commended, for it left no opportunity for a waste of time in fruitless debate. Much of the evidence was taken for granted, and remains for future scrutiny, but the conclusions were given to the Conference. With so many men producing the reasons upon which they based their tenets—that in this place or in that place we must look for the prime cause of rheumatic diseases, and that in this way or in that way relief can be secured—it was evident that debates upon details would defeat the object of the movement. Any discussions with the intent to prove that one circumstance or one method was more important than another in ætiology or treatment would have resulted in no clearing up of admitted confusion. The meeting had not been convened to evaluate the factors causing rheumatic diseases or the methods designed to meet them, but to collect evidence upon which such evaluation could be made. A sifting of the vast information now obtained should lead to practical measures in certain public directions where the needs have been indicated clearly. Further, it should bring about a classification of rheumatic diseases which will assist in the determination of the appropriate treatment. To this last question the third Session of the Conference

plied itself, when surveys were given of the methods hich had been found useful in the prevention of ronic rheumatism, of the place that vaccines may cupy in the treatment of underlying infection of the sults of vaccine therapy, and the scope of surgery the treatment of arthritic deformities. There was substantial amount of contradiction in the evidence, d accordingly there were opposing recommendations r treatment. But these things should be regarded a wholesome outcome of the deliberations, for the riations of view will form the proper terms of ference for the intensive inquiries which must llow, and for the institution of which the medical ofession can rely upon the cordial support of the nistry of Health.

Annotations.

"Ne quid nimis."

REORGANISATION OF THE INDIAN MEDICAL SERVICES.

INDIA definitely requires European assistance, not ly for the care of the military and civil European pulation, but for the maintenance in the country of at spirit of modern medicine which has accomplished eady such mighty things, and which day by day is reading in influence and value. Whatever changes ay be inherent in the Indian reform scheme, the rvival of this principle was in the minds of those ho framed the Verney-Lovett report, and of the Lee mmission, and the Secretary of State for India has ated repeatedly that in any scheme for reorganisa- n of the Indian Medical Service it would be essential earmark for the portion of the service not mediately engaged on military duties a number of il positions, especially research or professorial pointments. It would clearly be a gain, not only to cruiting, but to Indian public health itself, for the edical officers of the Service to be employed in the partments of research and teaching in which their edecessors have done so much for the welfare of dia. We have now at last the final decision of the overnment of India in regard to these matters, d during the week a communiqué has been issued aling in detail with the reorganisation of the medical rvices in India. The scheme now sanctioned is sed on proposals framed in consultation with local vernments. The Indian Medical Service, con- ituted on the same broad lines as at present, will retained primarily to meet the needs of the Indian my, and in order to maintain two essential requisites namely, (1) the necessary minimum war reserve of edical officers, and (2) the provision for European edical attendance on officers and their families. ocal governments in India will be required to employ stated number of I.M.S. officers. It has been lculated that the war reserve to be employed by the il side should consist of 134 British and 66 Indian ficers, the larger proportion of British officers being ue to the fact that they cannot be recruited on nergency in India from the ranks of private practi- oners. Medical attendance on British personnel, d the requirements of civil administration, for hich the Central Government is still responsible, volve the provision of a number of employments rmed "residuary," the incumbents of which must e retained permanently in civil employment, so as to sure the continuance under any circumstances of a keleton staff to cope with civil requirements. he total number of officers required for civil nployment in the I.M.S. is now calculated at 302, lotted as follows: war reserve, 200; residuary sts in provinces, 46; foreign and political depart- ents, 17; gaols, 8; special posts under the Govern- ent of India, 14; port health officers at Bombay d Aden, 2; reserve of 5 per cent. as allowance for ness, 15. Of this total 212 will be European and 90 Indian. To provide employment for these 302 officers, 237 posts are required, 59 of which will be available under the Government of India, and 178 (of which 112 must be held by British officers) will be provided in the provinces. The estimate of the medical requirements of European medical attendance is based on data which will change from year to year as the proportion of European to Indian civil officers diminishes; it will therefore be subject to scrutiny and revision. The remaining 66 posts will be open either to Europeans or Indians, while 28 out of 59 appointments under the Government of India will similarly be open to officers of either race. Complete lists of the residuary posts are appended to the communiqué. The adoption of the new list of posts will leave on the civil side a surplus of I.M.S. officers now holding appointments, but care is to be taken for the full preservation of their existing rights. Their prospects will be allowed to diminish only pari passu with the absorption of the surplus which will remain until the number of officers now in civil employ is equal to the number of posts reserved for them in the new list. The detailed measures to safeguard these prospects are being worked out. The communiqué also sets out the rules which will come into force forthwith as an integral part of the reorganisation scheme, and which have been drawn up to safeguard the varied, if not conflicting interests, of the three parties: the Indian army, the provincial governments, and the medical officers themselves. The scheme as set forth makes it clear what are the prospects, immediate and remote, for British recruits to the medical services in India. We have not hesitated to express the belief that the period of depression is now passing, and that the prospect is again bright for those who are fitted in physique and disposition for a medical career in India. That belief is strengthened by a perusal of the communiqué.

THE DENTAL BOARD.

OPENING the fourteenth session of the Dental Board of the United Kingdom Sir Francis Dyke Acland remarked on the loss of Mr. L. G. Brock who resigned his membership on taking up his duties as chairman of the Board of Control. If the Dental Board's parents, he said, were the Privy Council Committee and the Ministry of Health, and Sir Almeric Fitzroy was chiefly responsible for bringing them together, Mr. Brock was the midwife, monthly nurse, and nursery governess during its early days. His greatest and most permanent contribution was to be seen in the relations of the Board with the dental schools. "The fact that his work has obtained their respect, whether we have laid upon them conditions by which they could earn our grants, or whether grants have had to be refused, is surely," said Sir Francis, "a tribute to his fairness and impartiality." Mr. Brock's successor, Mr. M. Heseltine, had had an equally wide experience, and held a high position in the Ministry of Health. Among the points that would be brought before the Board at this session was a motion for a reduction of the retention fee, payable annually by dentists whose names were on the register, from £4 to £3. Every pound of retention fee meant about £9500 in income. The present income with an original registration fee of £5 and a retention fee of £4 was something over £2000 in excess of expenditure, but the surplus arose mainly from interest on specific reserves, and, if these were expended upon the objects to which they were allocated, the surplus would only be something over £1000. The retention fee would now automatically revert to £5 unless new regulations were made. Sir Francis was inclined to favour the reduction of the registration fee from £5 to £2, and of the retention fee from £5 to £2, during the first four years after qualification, so as to afford relief to young dentists when they needed it most. This arrangement would entail a loss of £6000 on an entry of 400. Good work had been done in bringing the advantages of the dental profession before head-masters of schools, several thousand copies of a

memorandum on the subject having been distributed. Dental health propaganda continued to expand. The demand for lectures was increasing rapidly. Certain aspects of the subject of dental clinics were likely soon to be sub judice. The Board could be assured that members of the Discipline Committee were fully alive to the possibilities of the commercialisation of dentistry which might be involved and to the danger to the public interest which this might entail. Action must be directed solely by the duty to see that the law, and the code of conduct proper to dentists, are maintained.

TREATMENT OF URTICARIA WITH ALKALIS.

URTICARIA is generally placed in the group of allergic phenomena, being attributed to a specific supersensitiveness of the individual to some protein poison, arising within or without the body. Prof. T. Schreus,[1] of Dusseldorf, endeavours to find an explanation of some cases—at any rate, the more obscure and intractable ones—in a relative diminution of the alkaline reserve of blood and tissues. He was led to an investigation of this metabolic factor by discovering that large doses of bicarbonate of soda are sometimes helpful in treatment, and that some patients can be cured by the intravenous injection of the drug. In order to test the hypothesis he estimated the alkaline reserve in 81 persons, using Barcroft's apparatus, and controlling his results by van Slyke's method. Twenty-two were subject to urticaria and the results indicated that in this disease, and in Quincke's œdema, there is a sensible lowering of the alkaline reserve. A comparative table shows his results expressed in terms of carbon dioxide volumes per cent. The readings are highest in pruritus and eczema (60·7 and 60·9 respectively), whereas in urticaria they may be as low as 53·7 and 53. One of the cases in which urticaria was controlled by bicarbonate injections had an alkaline reserve of only 46 volumes of CO_2 per cent. Afenil (calcium-urea) injections proved of no avail, and when ammonium chloride was administered there was a violent outbreak of wheals. Prof. Schreus does not claim that the diminution of alkaline reserve is responsible for more than a certain proportion of cases of urticaria, and it would obviously be unreasonable to regard the problem of this disease as solved. But it may be worth while to determine the alkaline reserve in intractable cases, and where it is low, to treat the patient with sodium bicarbonate.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

AT the annual general meeting of this, the oldest medical provident institution, held on May 16th, the report for 1927 was presented. During the year four members were elected, three died and one resigned. The Society now consists of one hon. member, 161 life, and 141 ordinary members, making a total membership of 303. The invested funds amount to £139,400. The income from investments was £4207 10*s.* 6*d.*; income-tax was returned to the sum of £872; and £358 was received in subscriptions and donations. During the year a legacy of £100 was received. The working expenses were £375. One widow died during the year and two were elected on to the funds; one orphan was also elected. £4782 was distributed in grants among 51 widows and seven orphans. In January a set of silver salvers was presented to the secretary, Mr. E. J. Blackett, in appreciation of his successful conduct of the case against the Inland Revenue authorities last year. The directors believe that the membership of the Society would be larger if it were better known and increase its membership. The Society is both provident and benevolent. Should a member die and leave his widow with an income not above £125 per annum, she would, on the present scale, receive from the Society a yearly grant of between £75 and £90, and any children under the age of 16 would receive a yearly grant of £60 each. Over the age of 16 special grants may be made to orphans to enable them to continue their education or start in some profession. These grants in many cases amount to £52 10*s.* a year to each orphan. The directors wish to attract the attention not only of newly qualified and newly married members of the profession, but also of medical men whose dependants would never be in need of assistance from the funds. These latter, either by becoming annual subscribers or by giving a yearly donation, would be helping the widows and orphans of their less fortunate brethren. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The subscription is small compared with the benefits that may be derived by unprovided dependants of a deceased member. The annual subscription for a member who at the time of his election is under 40 years of age is 2 guineas; if over 40 but under 50, 3 guineas; and if over 50, 4 guineas. There are special terms for life membership.

WATER: ITS POLLUTION AND ITS PURIFICATION.

IN his opening address on May 14th at a conference held this week under the auspices of the Society of Chemical Industry, the chairman, Lord Desborough, referred particularly to the efforts of the Thames Conservancy, of which he has been chairman for many years, to maintain a clean river. In view of possible future demands for additional water-supplies, he called attention to the general need for safeguarding the purity of the rivers of this country. Sir Alexander Houston developed the subject in an address on "Water Purification." The daily consumption of water in the area of the Metropolitan Water Board is, he said, 260 million gallons, of which about 60 per cent. is drawn directly from the river Thames. Deep wells yield 34 million gallons, and this is the only portion of the supply which does not need purification. The Thames supply is treated by double filtration and is then chlorinated. Moreover, storage itself acts as a very effective system of purification. Raw water containing 1000 colon bacilli per 100 c.cm. finally yields water showing their absence in 100 c.cm. The steady decrease in the incidence of enteric fever in London in recent years was a tribute to the work of the Board. The excess lime method of treatment had given very promising results especially in waters which needed softening as well as purification. Mr. J. H. Coste, F.I.C., spoke of the pollution of tidal and non-tidal streams. He pointed out that until recent years pollution of our rivers and streams was caused mainly by domestic sewage and refuse, but the modern growth of industrialism had added new sources of contamination. Among these were refuse from beet-sugar works, from wool-washing, and from tanneries, distilleries, and milk products works, also tar-washings from roads. Organic pollution of a stream produced slight opalescence of the water, and the growth of green and blue-green algæ and, when pollution was more pronounced, the growth of grey woolly sewage fungus. The mud became black and fermentation occurred with the evolution of gas, which, rising in bubbles to the surface, might carry with it masses of peaty matter and the river might smell. The general effect of all pollution was to degrade or destroy normal life in the affected stream. A river received more or less organic matter as well as salts in the form of soil washings, and these supplied sufficient nitrogen, phosphorus, and silicon to enable diatoms and algæ to thrive, and to attract a population of protozoa and small crustacea which, with insect larvæ, seemed to form the food of most fish. A balance of population of all kinds was reached, the plants utilising the carbon of carbon dioxide and bicarbonates, and giving up the oxygen required by the animals. Mr. Coste

[1] Münch. Med. Woch., 1928, lxxv., 340.

ferred briefly to the work of Butcher and Pentelow the river Lark in the Bury St. Edmunds district. lf-purification of a stream was effected by the idation of the organic matter causing the pollution, d at the temperature of natural waters this could ly be brought about by the agency of micro-ganisms. Apart from that liberated by photo-nthesis, the only source of oxygen available was e air, so that the rate at which water could absorb ygen from the air was a governing factor in deter-ning the effect of any pollution. This rate was mparatively slow, but at ordinary atmospheric mperature water saturated with oxygen contained volume about 7 parts per 1000. The rate of aeration of a partially deoxygenated water was portional to its lack of saturation due to the idising of the polluting organic matter. Thus a mplete absence of dissolved oxygen showed that trefaction might follow immediately; 70 per cent. uration showed that oxygen is being used up at per cent. of the possible rate, and so on. In a n-tidal stream the degree of pollution could thus be termined simply by examining the water above and low the point of pollution, but in a tidal river the oblem was not so straightforward, since the tide uld carry the polluting matter periodically up and wn, producing a zone of pollution both above and low the outfall. Mr. Coste called attention to the rk of the Ministry of Agriculture and Fisheries, ich, in conjunction with the Standing Committee on ver Pollution, is accumulating much information as the condition of many rivers in this country, gely from the point of view of the fisheries. The ief causes of unfitness of water for fish-life are: deficiency of oxygen, (*b*) presence of poisons, absence of necessary salts, (*d*) unsuitable tempera-re. The oxygen requirements of trout have been idied by Gardner and Leetham. At 4·7° C. they quire 102 c.cm. per kg. per hour and at 16° C. proximately twice as much. Many other varieties fish have been investigated in this connexion, and a general guide it may be taken that dissolved ygen in the water of a salmon or trout stream should t be below 70 per cent., or below 50 per cent. for ner fish. The 1868 Royal Commission on River llution resulted in the Rivers Pollution Act of 76, which, in its several clauses, prohibited the dition to streams of solid or liquid polluting matter, less the best practicable and available means were ed to render it harmless. "Streams" were defined, der certain circumstances, to include the sea and al waters. In 1923 the Salmon and Freshwater sheries Act gave Fishery Boards powers to control e discharge of trade effluents from new sources. As lessening existing pollution Mr. Coste expressed the inion that there should be no difficulty in produc-g a harmless effluent from ordinary sewage, most of e trouble in this respect arising from inadequate or solete works, or lack of skilled supervision. The atment of industrial trade effluents is as a rule more ficult, and each must be separately considered and alt with in a manner appropriate to its own special cumstances.

THE CERTIFICATION OF LUNACY: LAYMEN KNOW BETTER.

Two inquests held on May 12th gave occasion for mment on the fact that certification under the nacy Act is far from final. Both were cases where seemed not unreasonable to say that death resulted om the ignoring of expert medical opinion. One s an inquest at Hackney upon the death of a man who threw herself from a window in the ackney Infirmary. She had been under treatment the German Hospital, where the resident medical icer had certified that she should be placed under per control. She had been discharged from there the care of her husband on the authority of the ieving officer who, after a visit to the hospital, d decided that it was not a case he could deal with der the Lunacy Act. Presumably the relevant actments are Sections 13 and 20 of the Act of 1890; but at any rate the machinery which the law provides for preventing a certified lunatic from being at large and not under proper control and treatment broke down through no fault of the medical profession. The coroner, Dr. Edwin Smith, observed that by Act of Parliament doctors are given discretionary powers to say when an individual requires to be placed under proper control. "In my opinion they ought to be sufficient to satisfy relieving officers; it is unfortunate that in this case medical opinion was overridden but the relieving officer acted in accordance with his legal rights; if anyone is to be blamed, it is the framers of the Act, who could have closed the door to any possible overriding of a medical man's opinion by a layman not skilled in diagnosing medical diseases." The other inquest was at Eridge near Tunbridge Wells. A magistrate had refused to sign an order for a woman's removal to a mental hospital. Dr. Basil Pain, of Southborough, made a vigorous protest against the overriding of medical opinion, and Mr. Hillman the coroner, said there was no doubt that, if the magistrate had signed the order, the woman would be alive to-day. When medical practitioners are sued for damages for negligence in certifying that a plaintiff was insane, it has always been argued on their behalf that it is not the doctor's certificate but the magistrate's order which causes the lunatic to be placed under control. The case at Eridge strongly reinforces that argument. It is ridiculous to hold the doctor responsible if, as in these two cases, his opinion can be overridden.

A SURGEON'S SIXTIETH BIRTHDAY.

Prof. de Quervain's colleagues and pupils have taken the opportunity of his sixtieth birthday to issue a Festschrift or Jubilee book in honour of one who has served medicine, both national and international, no less than he has served the patients who have come under his care. Fritz de Quervain was born at Sitten on May 4th, 1868. After qualifying in 1894 he settled as surgical specialist in La Chaux-de Fonds, where he was surgical director of the local hospital until he was recalled to his old school at Berne as privat-docent. In 1910 he succeeded Wilms as professor of surgery in the University of Basle, and eight years later returned once more to Berne to succeed Kocher in the chair of surgery there. Over 200 scientific papers have left his pen, the larger proportion of them dealing with goitre, and then in descending order with tumours, tuberculosis, and surgical technique. His book on Surgical Diagnosis, which first appeared in German in 1907, has been translated into most of the languages of Europe and circulates freely among students and practitioners. Far from retiring into well-earned leisure, now he is a sexagenarian, Prof. de Quervain's colleagues congratulate him on retaining the zest and delight in work which has always been his characteristic. The Festschrift is to be published shortly, while the individual papers which it contains will appear in successive issues of the *Schweizerische Medizinische Wochenschrift*.

LYMPHADENOMA WITH RELAPSING PYREXIA.

AMONGST the cases described in 1832 by Thomas Hodgkin in his classical paper "Some Morbid Occurrences of the Glands and Spleen" we find one in which two attacks of intermittent fever occurred. In 1885 Osler called special attention to attacks of recurrent fever in Hodgkin's disease and pointed out that the glands increased in size during the fever and diminished again in the apyrexial intervals. But credit for the discovery of this phenomenon was subsequently given to P. K. Pel, who in the same year wrote of periodic rises of temperature in "a form of pseudo-leukæmia." His fame is shared by W. Ebstein, who in 1887 described "das chronische Rückfallsfieber, eine neue Infektionskrankheit." In a monograph [1]

[1] MacNalty, A. S.: An Investigation of Lymphadenoma with Relapsing Pyrexia. Ministry of Health Reports on Public Health and Medical Subjects. No. 50. 1928. 1s. 6d.

just published by the Ministry of Health, Dr. A. S. MacNalty supplies an extensive review of the literature of this condition and describes in detail 17 cases which have come under his personal observation. He finds that the cases fall into three clinical groups. In the first and most common type the external glands are enlarged, but not to a very great extent. During the pyrexial periods they may be painful, soft, and tender, but they do not become attached to the skin. The glands may remain of the same size during both febrile and afebrile periods, but occasionally some degree of enlargement is observed in the pyrexial periods with compensating diminution in the apyrexial periods. The second type is rare, but possesses distinct clinical features. In the apyrexial stage the glands may be small, freely movable and unattached to one another or to the skin. With the onset of pyrexia the clinical picture changes with marvellous rapidity. The glands swell up and a single gland may attain the size of a cricket ball; they are hot, painful, and tender to the touch, are apparently adherent to the skin, and the skin over them is red or purple and sometimes œdematous. They closely resemble suppurative glands on the point of discharging pus. But as lysis occurs the glands shrink down to their original size, and the pain, tenderness, and heat subside completely until the process is repeated in the next pyrexial period. The third type, also rare, is that in which the internal glands alone are involved. Relapsing pyrexia and progressive weakness from no discoverable cause are its salient features. Occasionally palpation of the abdomen or radioscopy of the chest may reveal the presence of enlarged internal lymphatic glands. The prognosis is bad in all three groups.

Cases of this disease often escape recognition owing to confusion with other maladies; of these tuberculous adenitis and chronic pulmonary tuberculosis present great difficulties in the differential diagnosis. When superficial lymphatic glands are enlarged and careful search fails to reveal any other tuberculous manifestation, one of the glands should be excised and submitted to microscopic investigation. This course should be pursued as a routine method, for, in the absence of other signs of tuberculosis, no other means of diagnosis is at present available. A mere pious opinion, unconfirmed by histology, that enlarged glands in the neck are due to Hodgkin's disease, may lead to prolonged radiotherapy and even to gross disfigurement before the condition is discovered to be tuberculous. Dr. MacNalty discusses at length the macroscopic and microscopic researches of D. M. Reed, F. W. Andrewes, W. T. Longcope, and H. M. Turnbull. We are grateful to him for his emphasis on certain points in the morbid anatomy—for example, the frequent occurrence of "Hodgkin nodules" in bone. But we regret that the Ministry of Health should have neglected this opportunity to give a lead in nomenclature and to allocate to this disease the title "Lymphogranuloma," which, on the showing of the pathologists quoted, it so clearly deserves.

THE IRISH FREE STATE REGISTER.

THE Register of medical practitioners in the Irish Free State is to be established on May 26th, after which date no one whose name is not inscribed therein will have the status of a medical practitioner in the territory of the Irish Free State. In the first instance the Register will include the names of all those whose names are on the General Register with an address in the Irish Free State, together with the names of any other practitioners registered in the General Register who may desire to be registered in the Irish Free State Register. All such names will be registered without fee up to May 26th. The names of those resident in the Irish Free State will be put on the list automatically, but all others must make application to the Registrar. After May 26th names will be registered only on the payment of a fee. It is important, therefore, for those who, not being at present resident in the Irish Free State, may contemplate ever engaging in practice there, to make application for registratio at once. In particular practitioners residing i Northern Ireland whose practice frequently or occa sionally carries them across the Border, should tak the necessary steps to secure their professional statu in the Irish Free State. The address of the Registra is Room 123, Custom House, Dublin.

WE have pleasure in announcing that the Govern ment duty on radium, which we deplored last wee in view of the rapidly increasing therapeutic import ance of the substance, is to be suspended. Th Treasury have made an order under Section 10 (5) o the Finance Act, exempting radium compounds fro key industry duty from May 15th to Dec. 31st, 192 and we have every reason to believe that the dut will not be re-imposed.

THE Royal Faculty of Physicians and Surgeons o Glasgow have appointed Mr. George Henry Edingto to be their representative on the General Medica Council.

A MEMORIAL tablet to Sir William Leishman wi be unveiled in the Chapel of the Queen Alexandr Military Hospital at 11.30 A.M. on Saturday, June 2nd

The Services.

INDIAN MEDICAL SERVICE.

THE NEW RULES.

IN a communiqué just issued by the Governmen of India, dealing with the reorganisation of th Medical Services in India (summarised on p. 1025 o our present issue), are set out the rules which hav been framed in the interests of the Army, the Loca Governments, and of officers themselves, as a integral portion of the scheme. These rules wi come into force forthwith.

1. Liability to serve on either civil or militar side will be a definite condition of service for a future entrants to the Indian Medical Service.

2. No officer will be transferred to civil employmen without the consent of the Government of India an Local Government.

3. An officer transferred to civil employmen will not ordinarily be liable to be recalled to militar employment (except on general or partial mobilisatio without the consent of the Local Government, bu the Government of India will retain the power t recall an officer against the wishes of a Local Gover ment in very exceptional cases of absolute necessit

4. A Local Government will not be at liberty without the consent of Government of India, t return to military employment an officer transferre to civil employment.

5. All officers in civil employment (including tho now in the Service) about a year before the date o which they are expected to be due for promotion t the rank of colonel, will be required to state wheth they wish to return to military employment, in ord that they may be considered for promotion t administrative rank.

6. Those officers who elect to return to militar employment will be recalled and employed in position suitable to their rank without, howeve any guarantee of eventual promotion.

7. The case of each officer will then be considere on its merits when his name comes up for promotio and (*a*) those considered suitable for military pr motion will be retained on the military side un promoted to administrative rank, after which th would not normally revert to civil employmen while (*b*) those not considered suitable for promotio will normally revert to civil employment or, subje to approval of military authorities, be given th option of remaining in military employment in th rank of lieut.-colonel until retirement.

. Those officers who do not elect to return to itary employment will either (*a*) sever their nexion with the Indian Medical Service and ome members of the Provincial Medical Service such terms as may be mutually agreed upon ween themselves and the Local Government, vhich case they will cease to belong to the War erve, or (*b*) will continue to belong to the Indian lical Service, in which case they will be eligible further promotion on the civil side, and will tinue to belong to the War Reserve provided that y do not hold residuary appointments. Also y will be eligible to receive promotion in military k, as at present, on the basis of the civil adminis- ive posts which they hold.

. An officer who desires permanent civil employ- nt, but does not succeed in obtaining it, will be ranteed employment in the Military Medical vices unless he is unfit for active service, or there ome other equally valid impediment to his being ployed on military duties.

NAVAL MEDICAL COMPASSIONATE FUND.

the quarterly meeting of the directors of the Naval ical Compassionate Fund, held on April 26th, the sum 175 was distributed among the several applicants.

ROYAL NAVAL MEDICAL SERVICE.

rg. Comdr. F. C. Robinson is placed on the Retd. List the rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

rg. Sub-Lieut. H. S. Waters to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

aj. A. T. Frost to be Lt.-Col., vice Lt.-Col. D. O. Hyde d.).

pt. (Prov. Maj.) C. H. G. Penny retires, receiving a uity and is granted the rank of Maj.

. J. D. Borham is placed on the half-pay list on account l-health.

. (on prob.) P. V. MacGarry from the secd. list is restd. ie estabt.

mp. Lt. A. F. Downie relinquishes his commn. on unt of ill-health.

. on prob. J. M. Quinlan resigns his commn.

ARMY DENTAL CORPS.

pt. A. E. Webb to be Maj.

TERRITORIAL ARMY.

pt. A. Mead, late R.E., to be Lt., and relinquishes the of Capt.

pt. W. K. Churchouse resigns his commn.

pernumerary for service with the O.T.C.: W. A. key supern. for serv. with the Med. Unit, Glasgow Univ. gt., Sen. Div., O.T.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

aj. G. B. Gill, from the Active List, to be Maj.

ROYAL AIR FORCE.

E. Alderson is granted a short service commission as ying Officer for three years on the Active List and is nded for duty with the Victoria Infirmary, Newcastle- n-Tyne.

ying Officer P. O'Callaghan resigns his short service mission.

ight Lt. T. Sheehan relinquishes his temporary com- ion on completion of service and is permitted to retain ank.

AUXILIARY AIR FORCE.

ie undermentioned Flying Officer (Honorary Flight Lt.) e Flight Lt.: No. 600 City of London (Bombing) dron: N. P. Henderson.

TERRITORIAL DECORATION.

ie King has conferred the Territorial Decoration upon . Col. Attwood Thorne, V.D., Majs. Norman Mello usson, John Francis Edmiston, Thomas William Selwyn s, James Alexander Stenhouse, and Frank Harris White.

COLONIAL MEDICAL SERVICES.

ie following appointments have been made by the etary of State for the Colonies: Dr. V. F. Anderson, st. M.O., British Honduras; Dr. N. V. McKenna, ., Federated Malay States; Dr. A. F. Brown, M.O., nda; Dr. D. E. Wilson, M.O., Tanganyika Territory; A. V. Clemmey, M.O., Tanganyika Territory; Lieut. F. G. Dickson, Sanit. O., Kenya; and Dr. E. J. kaby, Dist. M.O., Cyprus.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXVI.

THE TREATMENT OF ANEURYSM.

THE history of aneurysm and its treatment is a long one. The experience gained from the study of this disease, from the observations of Morgagni in the eighteenth century to those made during and after the Great War, enables us to-day, by the correlation of sound clinical observations and accurate pathological investigations, to undertake the treatment of this condition in a rational way. But all measures are unsatisfactory when the disease is once established and palliation of symptoms must then be the aim.

Aortic Aneurysm.

Preventive Measures.—The very close relationship between aneurysm of the aorta and syphilis—for only in rare instances is it due to other causes—is an indication of the need to begin antisyphilitic therapeutic measures early, before the development of symptoms and physical signs which characterise the disease have become manifest. The routine radiographic examination of the chest in patients suspected of cardiovascular syphilis makes this possible. If this method of examination were widely applied, and followed by suitable treatment with mercury, iodide, and arsenic the development of aortic aneurysm in many patients would be prevented. Mercury should be administered either by inunctions, injections, or by the mouth up to the point of saturation, and continued with free intervals of two or three months in the year, if the Wassermann reaction remains positive, for five years or longer. The Wassermann reaction is not likely to become negative in more than a quarter of the cases treated. A negative test is an indication to withhold mercurial treatment for periods up to six months in the year. Potassium iodide, grs. 30 daily, is an equally essential therapeutic measure. Larger doses are not easily tolerated, for this drug must be given over as long a period as the mercury with the same free intervals. Each year for five years there should be given a series of six to eight intravenous injections of N.A.B., 0·6 g. at weekly intervals. An initial dose of 0·3 g. as a safety measure is to be recommended. These injections may be given in the out-patient department or in a consulting-room, and no special precautions regarding diet and rest are necessary. Accidents are not likely to follow the administration of this drug given in this way, and no symptoms of consequence should result from such treatment.

It is difficult, apart from specific treatment, to lay down any definite rules useful in the prevention of aneurysmal dilatation in a patient with specific aortic disease. Such instructions as are usually given to patients with chronic valvular disease due to other causes are helpful in arresting the progressive changes caused by intercurrent infections, focal sepsis, unsuitable work, and an unhealthy mode of living. An acute infection is an indication for rest in bed which should be continued for at least a week after the fall of the temperature to normal, the greater the constitutional reaction the longer should be this period of rest. Focal sepsis should always be treated with a view to removing a source of toxic absorption. It is important in choosing an occupation to select one that allows the patient to live within the limits of his cardiac reserve. It should not be arduous, nor expose the worker to cold, dampness, and heavy winds. Well-lighted and properly ventilated rooms, a climate without extremes of temperature, and an altitude not higher than 1000 ft. above sea-level, are points to be considered. If the patient has an anxious state of mind the judicious use of sedatives is called for; of

these bromides are of the greatest value in the treatment of nervous symptoms. They may be prescribed alone, or added to the iodide mixture, and in combination with nux vomica when exhaustion is noticeable in spite of the fact that the patient is physically at rest or has undergone only slight exertion.

Pain due to Structural Damage.—If it has not been possible to prevent structural damage of the aortic wall symptoms will appear. Pain of an anginal character may be the outstanding clinical feature of the disease at this time. It is usually associated with coronary and myocardial changes. The treatment is that of angina pectoris of specific origin. Inhalations of amyl nitrite are indicated when the pain is paroxysmal and occurs at rest. Sodium nitrite, grs. 2, two or three times daily, may prevent the onset of pain caused by slight exertion. Potassium iodide, grs. 30 daily, or in larger doses for a short time, is a remedial agent which sometimes proves satisfactory in treatment of this symptom. Mercury is of less value, but should be given a trial. In many instances physical rest alone brings relief, and a month in bed with a simple diet is a wise recommendation, particularly when there are peripheral vascular changes and a raised blood pressure. If arsenic is given it is advisable to keep the patient in bed throughout the whole period of the injections. Many patients show no improvement; a few have less pain, but in others the symptom may be aggravated. There is thus a certain risk attached to this form of treatment, and the results are, on the whole, unsatisfactory.

A long period of many months with complete physical rest, a depletion diet, and a low fluid intake is sometimes advised. This is not justifiable if undertaken as a curative measure, but if all other methods of treatment for the relief of symptoms have failed, such a régime, if it can be endured, may be tried.

It sometimes happens that the gradual increase in size of the tumour is arrested by the formation of an organised thrombus, which, spread over the inner surface of the aortic wall, may fill a large part of the tumour cavity. Acupuncture, electrolysis, the insertion of long coils of wire and other foreign bodies, are methods of treatment which have been employed with the object of stimulating artificially the coagulation of the blood—a natural healing process. Unsatisfactory results have led to the abandonment of these surgical measures.

Pressure Symptoms.—In the natural course of the disease the symptoms which dominate the clinical picture and are an urgent indication for treatment, are those caused by the pressure of the aorta on neighbouring structures in the chest cavity. The irritating paroxysmal cough, due to pressure on a bronchus, accompanied by breathlessness in all grades of severity, is a distressing symptom. Alterations of posture or rest may be tried, but often the discomfort is relieved only by the administration of opium in some form. A morphine or codein linctus and a sedative inhalant may help, especially when there is laryngeal palsy from paralysis of the recurrent laryngeal. A useful prescription is:—

℞	Codeinæ phosphatis	gr. ½
	Glycerini	℥ xv.
	Spt. chloroformi	℥ ii.
	Aquam	ad ʒ i.

Expectorants are useful when bronchiectasis is present and should be combined with some antiseptic if there is much toxic absorption. When there is pressure on the œsophagus food must be given in small quantities and in liquid form if it is to be easily swallowed. The choice of food which is not bulky and is sufficiently nourishing can in most instances be left to the patient, who will be guided by his own experience and tastes. The boring, agonising pain from pressure on the vertebræ, the spinal cord, the brachio-cephalic and other spinal nerve routes, is an indication for sufficient morphia to give the patient a few hours sleep. Sometimes relief can be obtained from rest in certain positions. One may be comfortable in a sitting posture, another only when lying flat on his back or side.

When the pain is less severe aspirin, phenacetin and medinal in combination may have some effect and give the patient longer hours of sleep than he would otherwise have.

Slight bleeding from the aneurysmal wall should be treated by long and continuous rest; this should lessen the hæmorrhage, which may even cease for a time.

Aneurysm of the abdominal aorta, when below the level of the renal vessels, may give rise to pain with an iliosacral distribution. Proximal ligature for a few hours has led to a diminution in the size of the tumour and a relief of pain for a month or longer; fatal results of such ligature are frequent. Some successes have been reported, with fewer fatalities, from digital compression. Such surgical intervention is worth a trial when aspirin and morphia fail to relieve the pain.

Aneurysms in Peripheral Vessels.

When a peripheral vessel is the seat of an aneurysm of specific origin, surgical treatment may be recommended with the hope of obtaining a good result. The technique is intricate, particularly when a subclavian or iliac vessel is involved; the operation takes a long time, and careful aseptic precautions are necessary to avoid gangrene or some other serious disturbance of the peripheral circulation. Proximal ligation of the vessel, or ligation of the proximal and distal ends of the aneurysmal sac are operations devised to obliterate the sac and not interrupt the peripheral circulation in this region. Such operations are possible in an area where there are other vessels which can carry on the circulation interrupted by the occlusion of the aneurysmal sac. In other regions ligation is not feasible because of the anatomical distribution of the vessels; here complete excision of the sac and the union of the proximal and distal ends of the vessel by suture has been attempted with success in a large number of reported cases. Only those with a knowledge of the special technique required should attempt this operation. When the seat of the aneurysm is a small vessel it is sometimes possible by external pressure for many hours to obliterate permanently the aneurysmal sac.

These are operative measures valuable in the treatment of aneurysm of peripheral vessels of specific congenital or traumatic origin. Such treatment is not indicated in mycotic aneurysms of these vessels when part of a general infective process, as in malignant endocarditis. The disease is anyhow likely to be a fatal one, and the aneurysm is an accident unlikely to affect its general course.

Arterio-venous Aneurysms.

Arterio-venous aneurysms, the result of gunshot wounds, were frequently observed during the war when many of them were treated surgically with success. In civil life they are generally of traumatic origin. Some are congenital. When possible, the sac should be excised. Proximal ligation of the sac is a simpler operation, but gives less satisfactory results owing to the danger of embolism. This is an especially important consideration when the vessels of the neck are involved. The obliteration of the sac by ligation of the proximal and distal ends avoids the danger, and the possibilities of gangrene from the unsuccessful excision operation. It should be remembered that an arterio-venous aneurysm leads to enlargement of the heart and probably myocardial disease from malnutrition of the heart muscle. There is some evidence to support the view that the relationship between an arterio-venous aneurysm and cardiac disease is a close one, resembling in many ways the reaction of the heart muscle to a defective aortic valve.

THOMAS F. COTTON, M.D. McGill, M.R.C.P. Lond.
Physician to Out-patients, National Hospital for Disease of the Heart; Consulting Cardiologist to the Queen Alexandra Military Hospital.

THE HARVEY CELEBRATION:

ORGANISED BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A CELEBRATION of the tercentenary of the publication of "De Motu Cordis" was organised by the Royal College of Physicians of London to take place between May 14th and 18th. The programme of arrangements issued by the College commenced with the following summary of Harvey's life, and of the circumstances of the great discovery, while the connexion of the founder of physiology with the College was set out alongside full notes of the history of the College.

WILLIAM HARVEY.

William Harvey was born at Folkestone in 1578 d educated at the King's school of Canterbury and terwards at Caius College, Cambridge. After aduating in Arts at Cambridge in 1597 he set out r Padua, where he studied medicine for four years ıder Fabricius, Minadous, and Casserius, and in 02 received from that University the diploma of octor of Medicine, which is now in the possession this College. On his return from Padua Cambridge mitted him to her doctorate, and in 1607 he became Fellow of the Royal College of Physicians, and in 15 its Lumleian Lecturer. Meantime, in 1608, he d received a reversionary appointment as Physician St. Bartholomew's Hospital, which became solute in 1609. As Lumleian Lecturer Harvey pounded year after year within the College his ctrine of the circular movement of the blood, fore he gave it in its completed form to the world large, in 1628, by the publication at Frankfort of s "Exercitatio Anatomica de Motu Cordis et nguinis," dedicated to King Charles I., a copy of e first edition of which may be seen in the Library the College. (Fig. 1.)

In this volume, addressing the President of the oyal College of Physicians and his other fellow ysicians, he says:—

"I have already and repeatedly presented you, my learned ends, with my views of the motion and function of the art in my anatomical lectures: but having now for nine years d more confirmed these views by multiplied demonstrations your presence, illustrated them by arguments, and freed em from the objections of the most learned and skilful natomists, I at length yield to the requests, I may say treaties, of many, and here present them for general nsideration in this treatise."

The manuscript notes of the course given in 1616 ay be seen in the British Museum, or in excellent scimile reproduction in a volume prepared under ie supervision of a Committee of the Royal College Physicians.

During the Civil War Harvey was often in close ttendance as physician on King Charles I., both n the field of battle and at the Royal Headquarters t Oxford, where he became Doctor of Medicine in 642, and Warden of Merton College in 1645 for a ngle year. In 1648 he retired from active practice, nd spent the evening of his days at the house of one r other of his merchant brothers, more particularly t the Roehampton house of Eliab, who was a member f the Grocers' Company. Here he resumed his rmer work on the Generation of Animals, which as published in 1651 through the instrumentality f Sir George Ent. In this same year Harvey offered o build a Museum for the College, which was to be t once a library and a repository for simples and arities. In 1654 the completed building was handed ver, together with the title-deeds, to the College. n the same year the Fellows elected Harvey, who ad already been Censor in 1613, 1625, and 1629, nd Treasurer in 1628 and 1629, their President, but ge and failing health constrained him to decline the ffice. Nevertheless he continued to discharge his uties as Lumleian Lecturer until 1656, when on aying down this post he crowned his unceasing enerosity to the College with the gift of his partimonial estate at Burmarsh, in Kent. In his Deed of Gift he provided money for the stipend of the Librarian and the upkeep of the Library, and for an annual Banquet and Oration. He enjoined the chosen Orator to commemorate the benefactors of the College, stating what they have done for the College and calling on others to follow their example, and to exhort the Fellows and Members of the College to search and study out the secrets of nature by way of experiment, and to continue in mutual love and affection among themselves for the preservation of the dignity of the College. The Banquet and the Oration are held in the College annually on St. Luke's Day, Oct. 18th.

In 1657 this passionate searcher after truth, this generous, unworldly, religious man died, where he had chosen to live, in the house of one of his beloved brothers, that of Eliab, at Roehampton.

The prompt and universal acceptance of Harvey's discovery as an indisputable anatomical fact was hindered by the circumstance that he left one detail in the circular movement of the blood for future demonstration—namely, the precise mode of transference of the blood from arteries to veins. Malpighi made this known to the world in 1661, having seen by the aid of the microscope the passage of the blood through the capillaries of a frog's lung. He even caught a glimpse of the blood corpuscles in actual transit, but it remained for Kircher, Swammerdam, and Leeuwenhoeck to give them bodily form. As Malpighi was born in 1628, a tithe of homage in this Tercentenary Celebration may well be bestowed on him.

Surprise is sometimes expressed that the physiological harvest of Harvey's discovery was delayed so long in its ingathering. Harvey was well aware that this discovery touched only the fringe of the much wider problem of the purpose of the circulation. For this reason he styled his "De Motu Cordis" an Anatomical Exercise, and promised further treatises on Nutrition and Respiration, neither of which was destined to be born of his hand.

Before Harvey, the prevalent belief had been that the food became converted in the intestines into chyme, which was carried by the portal vein to the liver, and there converted into blood and endowed with "Natural Spirit," or the property of growth. Part of this low-grade blood was carried from the liver by the hepatic veins and the inferior vena cava to the right ventricle, where it gave off impurities by way of the pulmonary artery and the lungs, and after this purification ebbed to and fro for purposes of ordinary nutrition. A very small part of this venous blood did, however, pass through invisible pores in the muscular septum to the left ventricle, where it was mixed with air drawn in from the lung by way of the pulmonary vein, by the agency of active traction of ventricular diastole. Thus was produced a high-grade arterial blood, instinct with the principle of life, the "Vital Spirit," which ebbing to and fro in the arteries endowed the various organs with function. From such as reached the brain was distilled the noblest essence of all, the "Animal Spirit" or breath of the soul, which when carried out from the brain by the nerves initiated motion and sensation and the highest functions of the organism.

Harvey's demonstration that the same blood flowed perpetually in two interlacing circuits, from right to left and from left of the heart, visiting in its course the remotest portions of the body, swept away at one stroke the very foundations of all this fantastic speculation, and paved the way for a scientific explanation of the purpose of the circulation. So it is that the publication of the "De Motu Cordis" has been rightly acclaimed as The birthday of Physiology.

Historical Notes on the Royal College of Physicians of London.

The following notes recapitulating the mainstay of the Royal College of Physicians have also been extracted from the very informing programme:—

The Royal College of Physicians was founded by Thomas Linacre who, with the assistance of Cardinal Wolsey, obtained from King Henry the Eighth a Royal Charter, dated September 23rd, 1518, which granted the power to form a College for the purpose of controlling and protecting all those who were engaged in the practice of medicine in the City of London and for seven miles around. By a subsequent Statute, 14 Henry VIII, the powers of the College were extended so that authority was exercised over all who practised medicine throughout England, with the exception of those who were doctors of medicine of Oxford and Cambridge. Six physicians—viz., John Chambre, Thomas Linacre, Ferdinand de Victoria, John Francis, Nicholas Halsewell, and Robert Yaxley were named in the Royal Charter as the first Fellows of the College, and power was granted to them to elect a President, to add to their number, to make by-laws and regulations, and to license all those who wished to practise medicine in the City o London and seven miles around.

Thomas Linacre, the founder, was chosen the firs President of the College which owed its inceptio almost entirely to his forethought and energy Linacre had travelled in Italy, and had studied a several Universities in that country, especially a Padua. While in Italy he had been impressed wit the care and attention bestowed upon the study o medicine, and he, no doubt, compared this activit with the lack of enthusiasm in England. As a resu of these impressions he decided to found in England College designed to control, foster, and promote th study of medicine. When he founded the Colleg Linacre had in mind as a model the medical schools Italy, and so it comes about that the constitutio and composition of the College show some resemblan to those of the Italian Universities of Linacre's da The College was founded by Linacre, but its struggl for existence might have ended in failure but for th devotion and energy of Dr. John Caius who w President for ten years during the years 1555–157 Under his firm and sagacious rule the College gre and became firmly established. The debt it owes Caius can hardly be measured.

The College Houses.—The first meetings of th College, for the transaction of business, were held Linacre's house in Knightrider-street, in the Cit and here it remained until 1614, when a new hou was erected at Amen Corner, with a garden, on t site of the present house of the Canons Residentia of St. Paul's. This College House, which was occupation in Harvey's time, was burned down the Great Fire in 1666, and in 1674 the Colle removed to a new building in Warwick-lane in t

e belonging to the Crown, but leased to the College r 999 years.

The Library.—The medical books of Linacre, equeathed by him to the College, formed the nucleus the Library, and by gifts and bequests it increased ntil in 1660, the date of the first Catalogue, it umbered some 1300 volumes. In 1666 the Library as destroyed in the Great Fire, and only 140 volumes ere saved. After this disaster the Marquess of orchester, a Fellow of the College, and possessed of ne of the finest private Libraries in England at that me, bequeathed the whole of his books, amounting some 4000 volumes, to the College. To this equest the great value of the Library is largely due. ther valuable bequests were made from time to me, and in 1921 the late Dr. Lloyd Roberts equeathed the whole of his Library of early printed edical books to the College, a bequest second only that of the Marquess of Dorchester. The Library w contains about 50,000 volumes, of which more than 0 were printed before the year 1500, and over 00 before the year 1600. The Library is not nfined to medical books alone, for it contains ctions comprising early editions of the Classics, neology, Civil and Canon Law, Mathematics, and e Natural Sciences. It also contains about 350 anuscripts, some of them of great interest, a fine llection of some 5000 engraved portraits of medical nd scientific men, and a large series of Charters nd other legal documents relating to the history of e College.

Portraits.—The College possesses 130 portraits in l of distinguished Fellows of the College, and the llection is representative of many of the portrait inters in England during the last three centuries. esides these the College contains many busts and me miniatures and medallions.

The Insignia and Arms of the College.

The Insignia of the College (Fig. 2), which are figured in the programme, consist of the Mace in silver-gilt, presented in 1683 by Dr. John Lawson, a former President of the College, the Caduceus, a silver wand carried by the President on official occasions, and made for Dr. Caius in 1556, the Book of the Statutes, and the velvet Cushion on which the Book rests.

THE RECEPTION BY THE KING.

The celebration in honour of the tercentenary of the publication of the "De Motu Cordis" was formally opened on Monday, May 14th, when the delegates from all over the world who had accepted the invitation of the Royal College of Physicians of London were received by the King at Buckingham Palace at 11 A.M. There were presented to the King upwards of 100 delegates representing nearly 30 countries, by Sir JOHN ROSE BRADFORD, whose formal introduction of them was in the following terms:—

"By Your Majesty's gracious invitation we are gathered here to-day to celebrate the Three Hundredth Anniversary of the first publication of William Harvey's famous book, the so-called 'De Motu Cordis,' in which he announced to the whole world the discovery already made known by him to his own medical colleagues in his lectures before the Royal College of Physicians. This book Harvey dedicated to His Majesty King Charles the First.

"Harvey's demonstration that the same blood must flow unceasingly round and round the body, visiting its remotest parts, swept away the visionary speculations of his predecessors and paved the way for a scientific explanation of the purpose of the Circulation of the Blood. Thus it is the publication of the

'De Motu Cordis' has been rightly acclaimed as the Birthday of Physiology and of Scientific Medicine.

"Science knows no boundaries of race or nation, and obedient to this doctrine Representatives of Medical Science from many lands have joined with Representatives of the Universities and Scientific Societies of this Kingdom and of the Dominions of your Empire Overseas to pay homage to the memory of this great English Man of Science.

"Your Majesty, in identifying yourself with this Commemoration of Harvey's work, is but treading in the footsteps of your Royal Ancestors. King James the First and King Charles the First both set a true value on Harvey and made him their own Physician, and the latter supplied him with the bodies of deer from the royal herds for his anatomical studies. Harvey constantly brought to King Charles natural curiosities for his inspection, and exhibited to him much of his experimental work. Together also they shared the rare experience of watching the beating heart in a human subject through a defect in the chest-wall produced by disease.

"In the Civil War, too, Harvey stood by his Royal Master and was present at Edgehill, in charge of the young princes, Charles and James, and afterwards at Oxford, where by Royal Mandate Harvey was appointed Warden of Merton College.

"As President of the Royal College of Physicians of London, on whose roll of Fellows Harvey stands out as its brightest ornament, I have the honour to express to Your Majesty the dutiful thanks of every member of this Delegation for the honour of this Reception, by which your Majesty to-day participates in the Celebration for which we are all assembled in the Capital of Your Empire."

THE KING'S REPLY.

"I thank you sincerely for your Address. It is a great pleasure to me to join with my people in welcoming the many distinguished men from my Overseas Dominions, and indeed from all parts of the civilised world, now assembled in London in honour of the Tercentenary of Harvey's immortal discovery.

"I appreciate the comparison drawn in your Address between my part in to-day's ceremony and the action of my predecessors, who befriended Harvey in his life-time. I am proud to think that the Kings of England of that day, recognising Harvey's great gifts, granted their patronage and help in his work, and are thus entitled to the credit of having contributed to the new birth of medical science.

"The importance and value of William Harvey's work cannot be exaggerated. In an age when physiological knowledge was in a state of darkness and chaos, he laid the essential foundation for a science of physiology by demonstrating not only the fact of the circulation of the blood, but the manner in which it took place. He discerned and taught that the true method of scientific progress is by observation and experiment, and it is for this, and not merely as the author of a single discovery, however brilliant and fundamental, that we to-day do honour to the name of Harvey.

"Science, as you truly say, knows no boundary of race or nation. Harvey's own career is an instance of this. He was a graduate not only of our own Cambridge, but also of Padua, which Ancient and illustrious University I am happy to see represented here to-day. His great book was published in Latin, the universal language of learning, and won acceptance for itself and fame for its author throughout Europe. But though science is international, each country's contribution may still bear the marks of the national character. And here we may proudly note that Harvey, in his three-fold capacity as a successful physician in private practice, as physician to St. Bartholomew's Hospital, and as an eminent student and investigator, foreshadowed what is now, and has long been, characteristic of British physiology—the combination of research with medical and surgical practice, allied with a generous devotion to the service of the poor in the public hospitals."

THE RECEPTION BY THE ROYAL COLLEGE OF PHYSICIANS.

The delegates were received at the Royal Colle of Physicians, Pall Mall, at 3 P.M., when academic rob were worn, the library of the College presenting brilliant spectacle. Addresses were received fro universities and academies throughout the world, ea delegate as his name was called shaking hands with t President, and received from him a facsimile of t "De Motu Cordis." The President was seat flanked by the Censors with the insignia of the Colle arranged before them.

The President, having introduced the guests of t College to the delegates, stated that the object the celebration was to pay a tribute of respect Harvey and to the wonderful scientific genius whi he had displayed in bringing about his great discover

HONORARY FELLOWSHIPS.

The PRESIDENT then addressed the assembly. I said that the College authorities felt that it wou be apposite to institute Honorary Fellowships this occasion. There had previously been a fe Honorary Fellows, for instance Lord Dorchester, contemporary of Harvey, was such, and one of t former presidents had instituted on his own initiati the election of Honorary Fellows. But, althou the late King Edward VII. had accepted a Fellowsh in recent years this precedent had not been followe so that it was a new movement on the part of t College to revive or institute the honour, which this occasion would be conferred upon the Earl Balfour, Sir Ernest Rutherford, and Profs. Iv Pyotrocitch Pavloff of the Academy of Sciences Leningrad, and Karl Friedrich Wenckebach, of t Academy of Sciences, Vienna.

At the close of the ceremony the following eulog were delivered :—

EULOGY OF HARVEY BY SIR CHARLES SHERRINGTO

In William Harvey we bear in remembrance c who was Fellow, Censor, Treasurer, and, for a da President-Elect of this College; its benefactor gift and bequest, and part and parcel of its pride a honour being for ever a living spring of knowledge. Ea year he is commemorated in this place by the Harvei Oration, with its historic and distinguished roll orators, among them yourself, Sir, not two years ag

Now Time brings three and a half centuries sin his birth and three from his unforgettable book; a this welcomely representative assembly is met to b witness to the book and to the man. A book can be all of the man, yet, in science, even as in lette the book inalienably is of the man. His book embod not only Harvey's thought, but what his hand at beh of his thought contrived, searched for, and found.

At the Renaissance the spirit of man turned fr an old order, cabined within a rounded scheme things, to move and inhabit for itself afresh. Th new day broke first on scholarship and letters. science it reset the mechanics of the stars before bent to the study of terrestrial life. In this latte adventured first upon the outward forms of organ a organism. Later it turned to explore their inw meaning, the living function itself. For this last s the Renaissance *is* William Harvey.

Yonder his picture hangs. Stripping from it so years we may see him, at two and twenty, hair "l and curling," eyes "black and very full of spiri listening in the steep theatre at Padua to Fabrici who expounds in Latin the parts displayed below the anatomy table.

If to us the scene seem remote, being three centu back, to the young Harvey then and there th centuries seemed little. Aristotle and Galen in liv authority were for him as present in that room as Fabricius speaking. Why, therefore, so remote to much that then surrounded the young Harve The answer comes: Harvey's own work changed perspective of the whole.

Harvey was pupil and fervent admirer of the mast of antiquity. But his famous exhortation to oth

o search out Nature by experiment, he addressed arly to himself. Hence, after Cambridge and Padua, he year of Shakespeare's death finds him as Lumleian ecturer of this College, teaching from first-hand know-edge the surprising heresy and the inviolate truth that he whole blood as one blood circulates the body in wo successive circuits driven by a valved muscular ump—no other than that age-long thrice-veiled nystery, the heart!

Harvey for this discovery employed no means nor ppliance other than had been at men's disposal from lassical antiquity onward. His was the triumphing f the new spirit unaided save by its own freedom. He as the coming of modernity. Not that he was nodern utterly, for he let ten years pass between his iscovery and sending it to press. A slender book; nost of its references to authorities dead 19 to 15 enturies before, but in observation its every state-ient holding to this day. The message of its 49 small ages engendered modern medicine.

The message had to fight its way, and in some uarters did so slowly. Even after 70 years the arned Abercromby's "De Pulsus Varietate," dedi-ated to Robert Boyle, wrote: "More obscure than ne origin of the Nile is, in my opinion, the origin of ne pulse."[1] Harvey relied on the truth and the ıture. He could hardly have guessed the long train f gifted men who were to extend his work generation fter generation onward unbrokenly to Einthoven and tarling, so freshly lost to us, and to those others, o less active, with us to-day and of his own College, ale and Lewis, brilliantly extending by their dis-overies his discovery here in this his city where he ved and taught.

Self-restraint speaks in Harvey's book. To supply 49 small pages a refutation of 19 centuries' tradition f continuous error argues a fine restraint. Yet, once t least, self-revealingly he gives his spirit rein. elaxing his resolve to forego treating of the circu-ation's purpose, he forecasts the uses which must ccrue to the blood in virtue of its circulating; in hat forecast he bursts forth into a luxuriant passage. ts imagery flashes on us a Harvey, other than the larvey austerely proving a solved problem, a Harvey red with constructive imagination facing a problem esh and still to solve; that same Harvey who had sked the heart valves "Wherefore?" and they had old him; the vein-valves and the heart's motions, nd they had told him; a Harvey who on his note-ook's cover in red ink wrote as motto: "Everything s full of Jove!" This Harvey, too, had its part in larvey the discoverer.

Forerunning at two centuries' distance almost word or word the thought of Claude Bernard, Harvey verred: "the very vegetative acts of each item of nimal structure compass results as it were by art, lection and foresight." Harvey's philosophy of Jature was one of the deep springs of his enthusiasm. teading his favourite Virgil he would throw it down, xclaiming in admiration, "The man hath a devil!" lay we not of Harvey himself say in admiration, ephrasing his other phrase, "The man is full of ove!"?

Mr. President, the work of Harvey, the spirit of it o less than the import of it, provides his eulogy and nakes superfluous all other. His great discovery, side from its intellectual worth, secured an item of nowledge, than which no other single item has so erved to grow as from a seed medicine as we now now it. And to engender medicine is to engender a whole world of correlated knowledge and also of eneficence. The circulation of the blood and the neaning of the heart! May we not affirm that modern nedicine does in fact start there? And, that so, we nvisage Harvey in his perspective through the ages. 'ounder of modern medicine! He would himself ıave felt no term can carry richer or lovelier praise rom a grateful world.

[1] "Nili fontibus meo judicio obscurior pulsus origo est," Observationes de Varietate Pulsus. By David Abercromby. London, 1685.

In Memory of William Harvey.

By Prof. Franz Keibel,

ANATOMICO-BIOLOGICAL INSTITUTE, UNIVERSITY OF BERLIN.

The task has fallen to me to say a few words upon the anatomical relations of William Harvey's work, and first we must note shortly the relations of physiology to anatomy. Both sciences have a common origin and for this reason are closely bound together; while even in their terminal ramifications they are at the present day not yet entirely separated. I recall the fact that the wide field of joint physiology is filled for the most part by anatomists.

And so it was, even in higher degree, in the days of William Harvey, and we know that Harvey was not only a supreme experimental physiologist, but also an admirable anatomist. He says of anatomy that it should be learned "not from books but from dissections, not from philosophical dogmas but from investigation of the structure of the body."

Naturally Harvey, like all great discoverers, had his forerunners and left his successors to complete his work, but it is noteworthy that Andreas Vesalius, the great reformer of human anatomy, can only in a very limited degree be counted as a discoverer in spite of his excellent description of the heart. Vesalius could find no holes in the ventricular septum; despite this he assumed the passage of spirits through it, in this case agreeing with his great opponent Galen.

As Harvey's forerunner we must regard the unfortunate Servetus, who in his theological tract "Christianismi Restitutio" (1553) correctly described the lesser or pulmonary circulation. His work was burned with its author, but it has recently been conjectured that it came to the knowledge of Realdus Columbus, who describes the lesser circulation in the same way as does Servetus. But R. Columbo makes no mention of Servetus. Also as forerunners of Harvey should be named Cæsalpinus, Cannani, and Harvey's teacher, Fabricius, from Aquapendente, in Padua. Cannani had discovered the valves of the veins; Fabricius prints admirable illustrations of them. Fallopius should also here be named.

All these had the key of the great riddle in their hands, the riddle of which Harvey says himself at the beginning of his studies with Fascatorius, that "it is so difficult that God alone knows the solution." They knew a series of isolated facts through whose correct employment for inductive conclusions they might have solved the riddle of the function of the heart, but they failed to draw these conclusions, and so there belongs to William Harvey the full glory of having discovered the circulation of the blood and the function of the heart.

As followers-on of Harvey's work should be named Marcellus Malpighi, the discoverer of the blood capillaries, and Aselli, Pecquet, and Rudbeck, the discoverers of the lymph and chyle ducts. Harvey indeed freely uses the word "capillaries," but only for the finest branches of the arteries. He had rigidly deduced the connexion of the arteries with the veins, but never demonstrated it; the demonstration of this connexion was achieved by Malpighi, who employed the lung and urinary bladder of the frog. The discovery of lymph and chyle ducts are to be regarded as important supplements to the doctrine of the circulation of the blood. Malpighi's discovery falls in the year 1661. Harvey did not live to see it, having died in 1657, four years previously. In 1665 came Malpighi's discovery of the blood corpuscles.

A certain time was still needed before the doctrine of the circulation of the blood was accepted, so deeply rooted were the errors of Galen and so great the respect for the old physician who for centuries had been worshipped as a saint.

And naturally there now arose objectives and new lines of inquiry. I may mention here only the atrio-ventricular bundle, whose discovery by William His, junr., has been made during the lifetime of most of us, the bundle that has brought the most important revelations of the function of the heart.

Nor must we forget that Harvey was a warm champion of the comparative view and is therefore to be regarded as one of the founders of comparative anatomy.

But even the most recent researches into the heart and circulation rest on the foundation that Harvey with insurpassable and masterly wisdom laid down, and this foundation will endure so long as our learning endures.

Prof. Chauffard's Tribute.

Prof. A. Chauffard (Paris) expressed his gratification at being invited to pay a tribute to Harvey, not only as delegate of the Académie de Médecine, but on behalf of the French medical profession as a whole. To speak of Harvey and his book was a real joy to the physician. The general character of his scientific work was remarkable for three things—its courage, its maturity, and its modernity. Although the first blow against Galen's doctrines had been struck by Vesalius in 1555, and Servetus and R. Colombo had partly foreseen the existence of a pulmonary circulation, Harvey's theories ill accorded with current opinion and raised a storm of opposition. Willis said that no man who had reached the age of 40 years could be found who would adopt them. A work of courage, Harvey's book was also mature, for the oral report on his investigations had been given before the Royal College of Physicians in 1616, 12 years before its publication. The interval was filled by the long period of silent research, necessary to all great discoveries, in which the proofs were made complete and final. Genius might be called "a long patience." The third feature of Harvey's work was its modernity, for none of our present methods, such as could be known and employed at his epoch, were unfamiliar to him. Furthermore, he well realised certain of the clinical results of his discovery, though it was left to Lavoisier, a century and a half later, to reveal the physiological functions of the circulation of the blood. Harvey's book, however, contained more than the story of the circulation; it opened the road for all future research. New conquests had since been made —auscultation, graphic registration, radiography, electro-cardiography, and the gauging of arterial tension—but all these acquisitions of modern science had served to complete and crown Harvey's discoveries. They had contradicted and modified nothing. Nor must he be remembered only as the discoverer of the circulation; his published work was of infinitely greater scope, and even that was incomplete, since many of his writings had perished. What he wrote abounded in the astonishing variety and novelty of his period, and the man was in no way inferior to his work. Thus he had been one of those rare geniuses who are true benefactors of mankind.

A Congratulation from Athens.

The Greek Minister in London, M. Caclamanos, representing the University of Athens, presented on behalf of that University an address written in ancient Greek, and illuminated on vellum, the case bearing on it the owl of Pallas. The gist of the address was to trace the origins of medicine, in accordance with Galen, from chance discovery to systematised pursuit of an art, and thence to instructed teaching in treatment. Egyptian practice, the oldest in medicine, was held to have been based on casual findings; while the medicine of Hippocrates was based on reason, experiment, and the study of nature. With Galen we have the art and science of medicine divided into three sections, dealing with the chemical constituency of the human subject, the formation of the embryo, and the investigation of the structure by anatomy. Harvey's knowledge was based upon the study of these principles, and after 17 years of labour and experiment he discovered the circulation of the blood. The English nation did right to celebrate the three-hundredth anniversary of the writing of the famous treatise "De Motu Cordis," and the University of Athens was joining in the congratulations.

Banquet at the Grocers' Hall.

On the evening of Monday a banquet was give by the Master and Wardens of the Worshipfu Company of Grocers in their splendid City hal when the Master, Lieut.-Colonel Francis W. Heatl presided over a company, which included as we as the delegates, Ministers, and Peers, the Master the Rolls, the President of the Royal Society, an the official heads of many seats of learning, of th medical corporations, and of the medical services.

After the loyal toasts had been drunk, the healt of the Delegates was proposed by Lord Hanwortl the Master of the Rolls, who briefly set out the stor of the Grocers' Company from its inception 50 years ago, indicating also that the site on which the were dining, though not the actual hall, had bee occupied by the Company since 1653. Willia Harvey, he added, might well have dined here wit his brother Daniel, who was a member of the Guil Pointing out that the term grocer implied one who dea "en gros," he showed how the trading compar had developed as a Guild and had come to acqui the position to which it had attained as a civic for and as a great administrator of money in the cau of charity and education, while the specially medic nature of their activities had been inherited from previous union with the Society of Apothecarie He welcomed, in cordial terms, the representativ present from 28 countries, assembled to-day honour of Harvey, whom he ranked with Newt and Darwin as men who had been determined " learn what is true that they might do what is right He referred to the splendid courage showed by Harve not only in his defiance of tradition when worki along his individual lines, but in his attitude towar criticism later. To intelligent inquiry he ga reasoned reply, but to wild animadversions like tho of a certain Dr. Primrose, he replied not at all—in t words of Wordsworth "a primrose by the rive brim, a yellow primrose was to him, and it was nothi more." He coupled with the toast the names of Pr J. Van Der Hoeve, of Amsterdam, and Prof. G. Monrad-Krohn, of Oslo, and suggested that t former would be in his element in an after-dinn speech, as he was an authority on mental states association with digestion.

Prof. Van Der Hoeve replied in excellent Englis with an eloquent acknowledgement of the hospitali offered to the delegates, both by the Grocers' Compa and elsewhere, and said that he looked forward the visits to be paid to Oxford where Harvey had be Master of Merton, and Cambridge, where at Cai he had received his education.

Prof. Monrad-Krohn associated himself with t sentiments of the previous speaker, and, going to refer to the last time when he was in Engla as a delegate to the International Congress of Medici in 1913, said that he hoped that those internatio meetings would soon be revived again. He w moved, he said, to this reflection because Harv must always be regarded as an international fig who, though educated primarily in England, ow to the continent, especially to Padua, much of t learning which enabled him to make his gra discovery. But Harvey, he held, illustrated in marked manner the British mind, namely t independent attitude which refuses to accept conclusions of others simply because they receiving common acceptance.

The toast of "Prosperity of the Worship Company of Grocers," was proposed by Sir Jo Rose Bradford, who pointed to the great record charity and hospitality possessed by the Compa throughout its long life, and never more splendi exemplified than in this banquet given to the lead medical representatives of 20 countries, and t official heads of the medical profession in Gr Britain. The guests were thus representative medical education all over the world, and this v appropriate for the hospitality of the Grocers' Co pany, inasmuch as, renowned though all the C

uilds were for the exercise of this virtue, no Guild in ondon had done so much for the cause of medical search as the Worshipful Company of Grocers. For ie past 40 years the Company, he continued, had ssisted others to play Harvey's great game of search, both by their foundation of the Grocers' esearch Scholarships, and their noble generosity the Lister Institute, a generosity which had been xercised in a particularly timely manner, seeing ie damage that was being done by prejudice to the use of science in this country.

The Master, in a deliberately brief response, mphasised the pride which the Company took in rthering the cause of medical research and wished at the direct descendant in the female line from arvey, the Rev. Rossendale Lloyd, had been present the dinner.

THE DEMONSTRATIONS.

WILLIAM HARVEY AND THE CIRCULATION OF THE BLOOD.

A REPRODUCTION OF HARVEY'S ORIGINAL EXPERIMENTS DISPLAYED BY CINEMATOGRAPH.[1]

By Dr. H. H. DALE and Sir THOMAS LEWIS.

AMONG the items suggested for the tercentenary lebration of the publication of the "Exercitatio natomica de motu cordis" was the reproduction, the form of a series of demonstrations, of the ssections and experiments made by William Harvey mself, which formed his experimental proof of the rculation of the blood. We were invited by the oyal College of Physicians of London to organise ch a group of demonstrations, if we regarded it practicable.

On considering the proposal in detail, we came to ie conclusion that it would be difficult to ensure ie complete success of the scheme in this form. ll Harvey's experiments, indeed, are simple, and sy to reproduce; but some of the most important e such as, for one reason or another, do not lend iemselves readily to a direct demonstration of the nd proposed.

In some cases the phenomenon to be observed is ie which few can see at one time, and which cannot, the other hand, be produced several times on the me preparation. In others it is one which can reproduced with ease and frequency in the boratory, but not with the certainty at a particular oment which a public demonstration demands. In very case, again, the fact observed is now so familiar at its demonstration would have little interest by self. The whole interest lies in its historical gnificance, as a fact newly observed by Harvey, nd as a step in the argument by which Harvey ogressed from the knowledge of his time to the scovery which laid anew the foundations of hysiology on an experimental basis.

For all these reasons we formed the opinion that ie object in view could best be attained by making nematographic records of the things which Harvey w and of the experiments which he made, and by ranging these in logical sequence, in relation to his gument. To this suggestion the Royal College of hysicians gave their approval and their practical pport.

In making the film we have acted throughout in nsultation, but one of us (T. L.) has had the main sponsibility for its general scheme and arrangement, hile we have shared the performance of the xperiments. We have endeavoured to limit the emonstration to preparations which Harvey probably ade, and to experiments the performance of which e describes or implies in his writings.

It has been necessary, of course, to adapt Harvey's ethods of performing the experiments and displaying their results, so as to make them suitable for photographic record. Modern knowledge has also enabled us to use exclusively animals deprived of all sensation, either by destruction of the brain or by heavy dosage with an anæsthetic. Apart from these differences, we have employed only the simple means available to Harvey, and have endeavoured to carry out the experiments as Harvey himself performed them, and to record the results as he saw them.

Description of the Film.

The film opens with Cornelius Jansen's portrait of Harvey, which hangs in the Royal College of Physicians, London. The famous physician is seated. The hands of the picture are now seen on an enlarged scale and are represented as moving to take up an ancient treatise. We look over his shoulder to see a few pages of Galen's "De Venarum et Arteriorum Sectione," and his "De Usu Partium," of the "De Fabrica" of Vesalius, and the "Questiones Peripateticæ" of Caesalpinus, these being among the relevant works to which Harvey had access. Galen's doctrines, the dominant views in Harvey's time, are summed up briefly by means of a diagram. They are the doctrines that formed Harvey's starting-point. In part he substantiated Galen's views, in large part he refuted them as a result of the experiments which the film exemplifies, presenting them in the five following sections, each marked by an appropriate heading and diagram.

1. *Auricular Ejection.*—The first demonstration gives the evidence presented against the view that the ventricle fills by suction. It is the evidence of the normal sequence of chamber contraction and of the pumping of blood from auricle to ventricle.

2. *Ventricular Ejection.*—Here briefly are the main heads of evidence that the arteries are passive, that they are filled by the forcible ejection of blood from the ventricle into them. When the ventricle contracts it pales, becomes small and hard, the arteries expand and from the cut arteries blood gushes forth.

A brief summary of previous views relating to the pulmonary circulation is interposed, and the film proceeds to Harvey's third series of demonstrations.

3. *Passage through the Lungs.*—Pores in the interventricular septum cannot be demonstrated. The blood leaves the right heart by the pulmonary artery; it cannot return past the pulmonary valves. The presence of a way through the lungs to the left heart is demonstrated by injections.

In three steps Harvey has now shown that blood passes from the veins to the arteries, following a pulmonary course in so doing. He now passes on to his most crucial observations and original conclusions, illustrated in sections (4) and (5); it is at this stage that he first expresses the view of continuous motion and of movement in a circle; here his views diverge most notably from those of his predecessors.

4. *Continuous Movement from Veins to Arteries.*—In stating this evidence, he lays stress upon the quantity of blood which he calculates must be ejected from the left ventricle at each systole; this blood does not return. He calculates from simple data that the heart must within a short space of time eject more blood than is to be found in the whole body. Continuous motion can be displayed by obstructing the main veins or main artery, for the vessel empties beyond the obstruction and the blood accumulates behind it in each case.

5. The *Passages from Arteries to Veins* forms the final demonstration. The movements of blood in the human limb are studied; by obstructing now the artery and now the veins, the former is shown to fill from the centre, the latter from the periphery. Similar conclusions are formed by noting the effects of cutting through veins and arteries of living animals in their length; the former bleed peripherally, the latter centrally. Finally, the function of the venous valves, their control of the direction of the venous blood stream, is fully displayed in the human limb.

[1] The Demonstrations arranged by the Royal College of hysicians in the Physiological Department of University ollege, London, were given on the mornings of Tuesday and ednesday, May 15th and 16th.

His experiments complete, Harvey writes his book. The last part of the film represents him turning the pages of this work; his hands close the book and lay it on one side, before becoming still.

THE HEART-LUNG PREPARATION.

RECENT ADDITIONS TO OUR KNOWLEDGE OF THE CIRCULATION.

By Prof. E. B. VERNEY.

THE introduction of the experimental method to the solution of biological problems has made possible, and marks the beginning of, a series of investigations and discoveries to which the degree of control which we now possess over both physiological and pathological states in man, is directly and solely attributable.

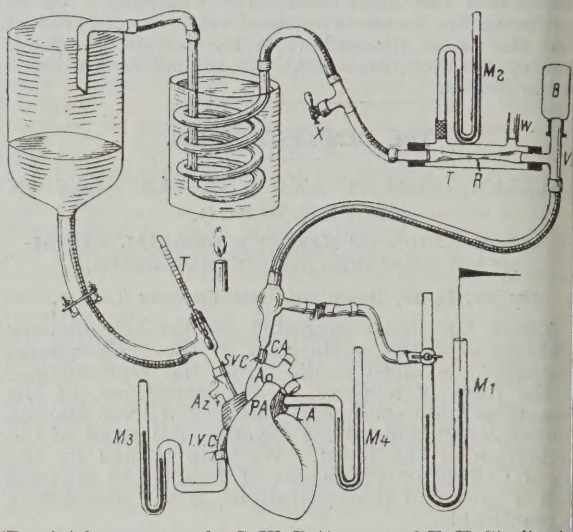
During the last 300 years physiological problems of fundamental moment have appeared and have been solved in rapid succession, the simultaneous extension of the mathematical and physical sciences on the one hand supplying effective weapons for their investigation, and on the other aiding in the rational interpretation of the results obtained. In the history of the physiology of the circulation, just as in that of any other branch of scientific knowledge, the discovery of a relationship of cause and effect between two phenomena has initiated attempts at formulating this relationship in a quantitative manner. And the success of such attempts is directly proportional to the degree to which uncontrolled and disturbing factors can be excluded from the investigation. The necessity for such an exclusion has prompted, therefore, in recent years the expenditure of a large amount of thought and practical ingenuity in the task of reducing a physiological problem to its simplest possible terms, in the hope that the accurate sketch so made of the fundamental processes at work may later be amplified so as to take its true share and position in the complete picture of the physiology of man.

Recent advances in the study of the circulation illustrate this tendency in contemporary thought and work. Sympathetic stimulation quickens the heart-rate, vagal stimulation slows it. Is the increased frequency in fever due to the effect of temperature directly on the pacemaker, or indirectly through the intervention of the cardiac nerves? During exercise the pulse accelerates, the stroke output and minute output of the heart increase. Is the acceleration a necessary accompaniment of an increased energy expenditure by the heart muscle, or are the two phenomena mutually independent? It is clear that, in order that questions such as these may be answered with a reasonable hope of truth, and especially if it is desired to probe more deeply into the mechanism by which the mammalian heart reacts to changes in the work which it is called upon to perform, a preparation must be available in which the heart is freed from all nervous control, and in which the supply of blood to the right auricle and the pressure against which the left ventricle ejects its contents, are under direct experimental control.

Such a preparation came into being chiefly through the ingenuity of the late Prof. E. H. Starling, and the researches which he and his pupils undertook with it have thrown a flood of light on the mechanism by which this organ reacts to changes in its environment.

The preparation was shown at the Harvey Tercentenary Celebrations by the Royal College of Physicians of London, and Starling's "Law of the Heart" demonstrated. The arrangement of the preparation is shown in the figure here given.

Blood passes from the venous reservoir on the left of the figure to a cannula provided with a thermometer and tied into the superior vena cava (SVC), thence to the right auricle, right ventricle, pulmonary artery, lungs, left auricle, left ventricle and aorta (Ao), through a second cannula tied into the brachiocephalic artery (CA), to the peripheral resistance TR. This is composed of a thin rubber tube R enclosed by a glass tube T, the air in the space between the rubber and the glass being subjected to any required pressure (measured by the manometer M2) by means of a hand bellows attached to the tubulure W. Thus the left ventricle is compelled, in order to eject its charge, to overcome this resistance which may be maintained constant or varied at will. From the peripheral resistance the blood flows through a warming coil to the venous reservoir to repeat the circuit already described. All the vessels conducting blood to and from the heart are ligatured with the exception of the superior vena cava and the



(Reprint from a paper by S. W. Patterson and E. H. Starling in the *Journal of Physiology*, 1914, xlviii., 357.)

brachiocephalic artery, both of which are provided with cannulæ as already described. Manometers M3 M4, may be connected to cannulæ tied into the inferio vena cava and left auricle respectively, and th pressures therein registered. A third manometer, M7 is connected to a side limb of the brachiocephali cannula and records the arterial blood pressure The lungs are not shown in the figure. A cardiomete is placed over the ventricles, and changes in thei volume registered by connecting it to a piston recorder In such a preparation, then, the inflow to the heart— alterable at will by adjusting the screw clip on th venous reservoir tube—the temperature and composi tion of the circulating blood, and the degree o peripheral resistance are under rigid experimenta control, and the systemic output of the heart ma readily be measured by taking the time of outflow of given volume of blood from the T-tube X.

Changes in the rate of venous inflow or in th peripheral resistance are found to be without effec on the rate of the heart, this being determined solel by the temperature of the blood-supply. Furthermore changes in rate occasioned by alterations in th temperature of the blood do not influence the minut output of the heart, this being determined solely b the venous inflow. Any increase in the work whic the heart is called upon to do is accompanied b an augmentation in its diastolic volume, be thi increased work occasioned by a rise in the peripher resistance or by an increase in the venous inflow The heart, therefore, dilates in order to do more work the energy liberated by each contraction bein determined by the initial length of the muscle-fibr just as is the case in skeletal muscle. This relationshi between the length of the heart-fibre and its power o contraction was called by Starling "the law of th heart."

More recent experiments by Starling and h pupils have shown that there is a direct linea relationship between the diastolic volume of the hear and its oxygen consumption. During the cours of an experiment with the heart-lung preparation

t is found that with a constant output of mechanical work the heart gradually dilates—loses its "tone"—the dilatation being accompanied by a corresponding increase in the oxygen consumption. It has become possible, therefore, to define the tone of the heart muscle in terms of its mechanical efficiency, that is to say, in terms of the ratio between the external work performed and the total energy liberated over a given period of time.

Contributions to medicine of such fundamental importance as these could only have been made on the heart freed from the multitude of influences, nervous and chemical, which serve to complete the picture of its power and means of adaptation to changes in the work which it is called upon to perform. And now by the experimental superposition of these "influences" upon the initially isolated heart, one is becoming able to visualise with much more precision than has hitherto been possible, their relative importance and actual share in such a complex cardiovascular picture as is presented for example in muscular exercise or in heart failure in man.

The demonstration of the heart-lung preparation emphasised one method of approach to physiological problems connected with the circulation, a method of approach which has been amply justified in its conception by the results of far-reaching significance which have already been obtained through its prosecution.

Luncheon to Delegates and Guests in the Great Hall of St. Bartholomew's Hospital.

On Tuesday, May 15th, a luncheon was given by the Treasurer, Almoners, and the Medical Staff of St. Bartholomew's Hospital to the delegates and guests to commemorate William Harvey, physician to the hospital, 1609–1630. The attendance was large, the chair being taken by Lord Stanmore, treasurer of the hospital. After the Chairman had welcomed the delegates and guests, Sir Wilmot Herringham, consulting physician to the hospital, gave an address on Harvey's connexion with the hospital. He described Harvey's work with the hospital, pointing out that he drew up rules for the regulation of the patients. Among these were that no one should be admitted for trivial or incurable diseases, and that those suffering from venereal disease should be isolated. Also, that no patient should stay in the hospital beyond a certain time, and those who refused to obey the rules or to take their medicine should be summarily discharged. He further ordained strict rules for the staff, the chief of which was that the surgeons should be strictly under the thumb of the physicians. Sir Wilmot pointed out that Harvey was almost as much of a surgeon as a physician, and it was because the physicians of that time were the better educated members of the profession that they dominated the surgeons, this being the *raison d'être* of Harvey's discriminating injunction. The speaker drew attention to the fact that Harvey was a cultured man. As witness of this he was sent by King Charles I. to choose pictures for him on the Continent. Harvey lost his post in the hospital on account of his allegiance to, and friendship with, the King. Harvey was a staunch family man and a man generous both in public and private life. He was a friend of the learned men of the day, the Earl of Arundel, John Selden the great jurist, Hobbes the philosopher, and Bacon. It was Harvey who said of Bacon that he taught philosophy like a Lord Chancellor. Sir Wilmot summed up the characteristics of Harvey when he said that he was a scientific man in the modern sense of the word, and his name is linked with a discovery greater than any made by Hunter, though Hunter, coming later, possessed deeper knowledge in particular directions. Hunter may be termed the father of pathology and Harvey the father of physiology.

Sir John Rose Bradford returned thanks to the Governors of the Hospital for their hospitality and paid tribute to Sir Wilmot Herringham for his wise, humorous, and eloquent address on Harvey, declaring that of all the speeches in memory of Harvey none would live longer.[1]

Lord Stanmore replied on behalf of the hospital.

Conversazione in the City.

On the evening of Tuesday the Prince of Wales attended a reception held by the Royal College of Physicians at the Hall of the Merchant Taylors in Threadneedle-street. The President and Lady Bradford received a large gathering of delegates, Fellows of the College, and their guests, and the evening was spent in conversation, to the strains of the band of the Welsh Guards.

List of Delegates.

Representation of Foreign Countries.

Argentine.—University of Buenos Ayres: His Excellency Dr. José Evaristo Uriburu.

Austria.—Academy of Sciences, Vienna: Prof. K. F. Wenckebach.

Belgium.—Royal Academy of Medicine, Brussels: Prof. P. Nolf. University of Louvain: Prof. Bouckaert.

Czecho-Slovakia.—University of Prague: Prof. Frantisek Mares and Dr. Syllaba.

Denmark.—University of Copenhagen: Prof. Oluf Thomsen.

Egypt.—University of Egypt, Cairo: Dr. A. A. Ismail.

Finland.—University of Helsingfors: His Excellency M. A. H. Saastamoinen.

France.—University of Paris: Prof. Pierre Teissier. Academy of Medicine, Paris: Prof. A. Chauffard. Pasteur Institute, Paris: Prof. Delezenne.

Germany.—University of Berlin: Prof. F. Keibel. University of Frankfort: Prof. A. Bethe. University of Leipzig: Prof. M. Gildemeister. Prussian Academy of Sciences: Prof. Max Rubner.

Greece.—University of Athens: His Excellency Demetrios Caclamanos.

Holland.—University of Leyden: Prof. J. A. J. Barge. Royal Academy of Sciences, Amsterdam: Prof. J. van der Hoeve.

Hungary.—University of Budapest: Prof. Lajos Nékám.

Italy.—University of Bologna: Prof. M. L. Patrizi. University of Padua: Prof. A. Castiglioni. Academy of Medicine, Rome: Dr. Aldo Castellani, K.C.M.G.

Japan.—Universities of Japan: Mr. W. Moriya, Secretary to the Japanese Embassy.

Norway.—University of Oslo: Prof. G. H. Monrad-Krohn.

Poland.—University of Warsaw: Prof. G. Modrakowski.

Roumania.—University of Bucharest: Prof. D. Ionescu and Dr. S. Lalu.

Russia.—University of Kazan: Prof. A. Samoylov. Academy of Sciences, Leningrad: Prof. I. P. Pavlov.

Sweden.—University of Upsala: Prof. Gustav Göthlin. Royal Swedish Academy of Sciences, Stockholm: Prof. J. E. Johansson.

Switzerland.—University of Berne: Prof. Leon Asher. University of Geneva: Prof. Maurice Roch.

United States of America.—Harvard University: Prof. Stanley Cobb. Johns Hopkins University: Prof. F. J. Goodnow and Prof. W. H. Welch. University of Pennsylvania: Prof. W. H. F. Addison. College of Physicians, Phil.: Dr. F. R. Packard. Rockefeller Institute: Dr. Rufus Cole.

British Representatives: Dominions Beyond the Seas.

Australia.—University of Sydney: Dr. C. B. Blackburn.

Canada.—University of Toronto: Dr. R. D. Rudolf.

India.—University of Calcutta: Sir Leonard Rogers.

Malta.—University of Malta: Dr. Edgar H. Ferro.

New Zealand.—University of Otago: Dr. Daniel Colquhoun.

Tasmania.—University of Tasmania: Dr. John Bruce Hamilton.

British Isles.

England and Wales.—Royal College of Surgeons: Sir Berkeley Moynihan, President. Society of Apothecaries: Dr. R. Whiteside Statham, Master. University of Oxford: Sir Farquhar Buzzard, Regius Professor of Medicine, and Sir Archibald Garrod. University of Cambridge: Sir Humphry Rolleston, Regius Professor of Physic. University of London: Lord Dawson of Penn. University of Durham: Sir Thomas Oliver. University of Manchester:

---

[1] The address will appear in full in the next issue of the St. Bartholomew's Hospital Gazette.

Prof. F. Craven Moore. University of Birmingham: Sir John Robertson. University of Liverpool: Prof. John Hay. University of Leeds: Dr. J. B. Baillie, Vice-Chancellor. University of Sheffield: Frof. A. J. Hall. University of Bristol: Prof. Edward Fawcett. University of Wales: Prof. T. Graham Brown. Royal Society: Sir Ernest Rutherford, President. Medical Society: Mr. H. W. Carson, President. Zoological Society: Duke of Bedford, President. Royal Society of Medicine: Sir James Berry, President. Harveian Society: Dr. Herbert French, President. The Lister Institute: Major-Gen. Sir David Bruce. Physiological Society: Prof. Joseph Barcroft. Anatomical Society: Dr. E. Barclay-Smith. Pathological Society: Prof. H. R. Dean. Ministry of Health: Sir George Newman. Medical Research Council: Sir Thomas Lewis. Naval Medical Service: Surgeon Vice-Admiral A. Gaskell, Director-General. Army Medical Service: Sir Matthew Gregson Fell, Director-General. Royal Air Force Medical Service: Air Vice-Marshal D. Munro, Director. Indian Medical Service: Lieut.-Colonel J. K. S. Fleming. British Association: Sir Charles Sherrington. British Medical Association: Sir Robert Philip, President. London School of Hygiene and Tropical Medicine: Dr. Andrew Balfour.

Scotland.—University of St. Andrews: Prof. Adam Patrick. University of Aberdeen: Prof. J. A. MacWilliam. University of Glasgow: Prof. T. K. Monro. University of Edinburgh: Sir E. Sharpey-Schafer. Royal Society of Edinburgh: Mr. A. Logan Turner. Royal College of Physicians: Dr. Robert A. Fleming, President. Royal College of Surgeons: Mr. Alexander Miles, President. Royal Faculty of Physicians and Surgeons, Glasgow: Dr. G. H. Edington, President.

Ireland.—University of Dublin (Trinity College): Prof. A. F. Dixon. University of Belfast: Prof. J. A. Lindsay. Royal College of Physicians: Dr. W. A. Winter, President, Royal College of Surgeons: Mr. A. Fullerton, President.

Corporation of Folkestone (Harvey's Birthplace): Mr. Reginald Gilbert Wood, the Mayor. King's School, Canterbury (Harvey's School): Mr. Algernon Latter, late Headmaster. St. Bartholomew's Hospital (Harvey's Hospital): Lord Stanmore, Treasurer. Caius College, Cambridge (Harvey's College): Sir Hugh Anderson, Master. Merton College, Oxford (where Harvey was Warden): Mr. T. Bowman, Warden. Representative of the Harvey Family: The Rev. Rossendale Lloyd.

CHARTERS FOR HOSPITALS.—The London Homœopathic Hospital and the Royal Victoria Hospital, Dundee, have petitioned the Privy Council for the grant of Charters of Incorporation.

NATIONAL PHYSICAL LABORATORY.—A reception will be held at this laboratory at Teddington on June 26th, at 3 P.M., when the work of the laboratory will be open to inspection. Medical guests will be specially interested in the department of radiology. According to the report for 1927 (H.M. Stationery Office. 7*s.* 6*d.*), this department has devoted much time to the problems of X ray protection, particularly in connexion with the revision of the recommendations of the X Ray and Radium Protection Committee. Dr. C. W. C. Kaye, the superintendent of the department, states that the laboratory has dealt with many inquiries for information on this subject from institutions and private individuals, both at home and abroad. Routine tests of X ray protective materials have fallen in number during the year, but the work of inspecting completed X ray installations has increased considerably. The measurement of X ray intensity has received further consideration and the work of foreign investigators in this field has been studied. As a result, it is proposed to undertake experimental work, using a Bencken ionisation chamber in which the ionisation is produced in a gas at high pressure. Work of this kind, it is hoped, will lead to the standardisation of X ray intensity meters. The absolute absorption of X rays of a variety of specific wave-lengths has been measured in several different pure metals. It was the work of Prof. A. E. Owen, sometime secretary of the Rontgen Society, that revealed the important relationship between the wavelength of X rays and their absorption in matter. The accuracy aimed at in the present investigations shows that radiology is well on the way to becoming an exact science, where accurate measurement will be possible. The increasing importance of general radiology has led during the year under review to the formation of a department to investigate the application of the methods of X ray crystal analysis to industrial problems. It would be convenient if the reports of superintendents of different departments of the National Physical Laboratory could be issued in separate parts, since its scope is now extremely wide.

Special Articles.

MEDICINE AND THE LAW.

Removal of Name from Dentists Register.

THE King's Bench Division on May 10th decided an important point under the Dentists Act in the case of Pickup *v.* Dental Board of the United Kingdom. Section 13 of the 1878 Act provides that a person registered in the Dentists Register who has been convicted of a felony or misdemeanour (or has been guilty of infamous or disgraceful conduct in a professional respect) shall be liable to have his name erased from the Register. The question arose as to the meaning of "misdemeanour." Does it mean a misdemeanour triable on indictment or has it the wider meaning of any offence which is less than a felony whether triable on indictment or summarily? The Lord Chief Justice held that "misdemeanour" in Section 13 has the wider meaning. He quoted the judgment of Lord Alverstone in Du Cros *v.* Lambourne (1907, 1 K.B., 40) where the then Lord Chief Justice cited with approval the following passage from a well known text-book: "This word, in its usual acceptation, is applied to all those crimes and offences for which the law has not provided a particular name. . . A misdemeanour is, in truth, any crime less than felony." Lord Hewart was strengthened in this view because Section 13 of the Dentists Act contains a proviso which inter alia directs that a dentist is not to have his name erased because of a conviction for "an offence which, though within the provisions of this section, does not, either from the trivial nature of the offence or from the circumstances in which it was committed, disqualify a person from practising dentistry." This proviso seems to contemplate that the offences might be of a trivial nature and that because of their trivial nature, the person convicted might be allowed to retain his name on the Register. Mr. Justice Avory (who, when at the bar, argued for the opposite meaning of "misdemeanour" in Du Cros *v.* Lambourne) and Mr. Justice Shearman concurred. The result was that the court dismissed Mr. James Pickup's appeal from the order of the General Medical Council that his name be erased from the Register on the ground that he had been convicted of misdemeanour. The point is significant for medical as well as dental practitioners since the same phrase as to conviction for felony or misdemeanour occurs in Section 29 of the Medical Act of 1858, though the proviso as to trivial offences is not there expressed in the statute, but is tacitly left to the good sense of the General Medical Council. An obvious instance of a trivial offence involving no professional disqualification would be a conviction for exceeding the speed limit or some other similar charge inevitable in the case of those whose work obliges them to use a motor-car.

Alleged Delay in Notifying Tuberculosis.

At a meeting of the Carlisle Health Committee at the end of April complaint was made by the medical officer of health of the delay in notifying cases of tuberculosis. Some members of the Committee were inclined to urge prosecution, but their deputy clerk pointed out that there might be a legal difficulty in proving the date at which the practitioner became aware of the patient's infection. It appeared that a circular letter had been sent round to the medical profession a few months before, and the Committee decided to send out another warning. Dr. J. Beard, the medical officer, had stated that there was still a large number of cases in which notification was not received until just before the death of the patient. The complaint was, it seems, of delayed notification rather than of failure to notify. If the delay is due (as was suggested) to a desire to respect the feelings of the patient's family, it is for consideration whether safeguards cannot be provided to reassure the public by preventing publicity.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

University Physical Welfare Fund.

THE new draft Ordinance of the University Courts of the four Scottish Universities is a document of importance. It has been resolved: (1) that it is expedient to make further provision for the maintenance and improvement of the physical welfare of the students attending the universities; and (2) that an addition of 10*s.* 6*d.* should be made to the present matriculation and entrance fees to be applied towards meeting the cost of such provision. Dr. Alexander Morgan, late Director of Studies under the Provincial and National Committees for the Training of Teachers, said at the Edinburgh University Council that to those familiar with the difficulties and hardships of Scottish student life this ordinance would be welcome. It opened out great possibilities of beneficent activities and it would increase the confidence of parents and public authorities in the development of the university education.

The Budget and the Reform of Local Authorities.

The scheme sketched by the Chancellor of the Exchequer means a radical reform of all the local health and medical authorities. The whole financial and administrative systems will be integrated in a way impossible until now. Already the Scottish burghs have begun the active discussion of the proposals as they affect burghal administration. For a generation there has been a growing desire to widen the basis of local administration, and this cannot be effectively done without a reform of rating systems. Whatever modification of detail may be required in adjusting poor-law, public health, insurance, and other medical services, the broad result will secure to Scotland greater efficiency in every leading service. The experiment carried out by the Education Act of 1918 proves that the larger education authority is able to do work that was impossible under the smaller school boards, and the same will doubtless be true of medical services under the reorganisation.

Cream Preservative Once More.

Major Walter Elliot, Under Secretary of State for Scotland, in a letter to Brigadier-General Charteris, M.P., explains that the Board of Health is in agreement with the decision of the Departmental Committee that there shall be no preservative allowed for "double cream." The Secretary of State, therefore, as President of the Board, withholds assent to the suggested delay of "five or six years." Meanwhile, experiments are going on at Cumnock Creamery with a pasteurising plant adapted to the pasteurisation of cream. The claims for this plant are high; but given the proper selection of milk and reasonable care with the process, the results are apparently satisfactory. Further experiments will no doubt be made.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Inoculation against Diphtheria.

THE winter's epidemic of diphtheria in Paris has clearly shown the value of Ramon's anatoxin. This is obtained by heating diphtheria toxin and adding to it 40 per cent. commercial formalin in the proportion of 1 in 2000. Treated in this way the toxin becomes atoxic, whilst keeping its antigenic properties. Anatoxin is obtainable in boxes of three ampoules, each containing 2·0 c.cm., the liquid being tinted green. Either two or three injections are given, the first being 0·5 c.cm., and the second 1·0 c.cm., given a fortnight after the first. In 87 per cent. of cases the Schick reaction becomes negative after the second, which makes a third injection unnecessary; if required it is given after an interval of a week. In case of urgency it may be desirable to produce a passive immunity with purified serum.

Zoeller and Ramon now recommend vaccination via the nasal mucous membrane for patients who object to subcutaneous inoculation. Against diphtheria they protect the patient by instilling concentrated glycerinated antitoxin into the nose every second day. Two and sometimes three courses of treatment, lasting six days, with intervals of a week to a fortnight between them, have proved sufficient to convert a positive into a negative Schick reaction. The method has the advantage of being easy to apply and of not provoking any vaccinal reaction, but it is less precise than subcutaneous inoculation, and fairly large doses of antigen are required. Local vaccination is said to be as successful in preventing dysentery, tetanus, and scarlet fever, as it is in the prophylaxis of diphtheria.

Intermittent Albuminuria Traced to Ingestion of Milk.

Widal and his school have shown that milk can produce colloidoclasic crises in persons who have hepatic insufficiency, but as far as we know it has never been noticed that ingestion of milk may be followed by the appearance of albumin in the urine. This is the original feature of a case reported recently by Barbier. The patient had albuminuria every morning and evening, because at breakfast and dinner he drank a glass of milk. When this habit was discontinued the albumin disappeared. It would be interesting to know whether anyone else has observed a similar phenomenon.

Treatment of Human Trypanosomiasis.

Tryparsamide is generally used in the treatment of trypanosomiasis, but at the Pasteur Institute a new remedy has been produced under the name of "270 Fourneau." This product has been tried in the French Congo, and the results already show that its effects are entirely comparable with those of tryparsamide. The best indication of cure is the return of the cerebro-spinal fluid to normal, and this occurred at the end of the first course of injections, provided that at least 0·25 g. per kg. of body-weight had been injected. Administered in one long course, "270 Fourneau" seems to give results as satisfactory as, if not better than, tryparsamide. It is injected subcutaneously.

Biological Reactions in Tuberculosis.

The diagnosis of latent tuberculosis is exceedingly difficult, and in order to be certain, it is necessary to make use of biological reactions. In children a cuti-reaction fulfils all needs, but in adults one must have recourse to the reaction of fixation. The cuti-reaction is positive in persons who have harboured tubercle bacilli for even a brief period, and is thus positive in 80 to 97 per cent. of adults, which makes it almost valueless in practice. The reaction of fixation, however, is only positive in 10 to 15 per cent., and according to Prof. Rieux it answers the question of infection without ambiguity.

Raymond-Hamet has presented to the Académie des Sciences a report of his studies on the plant uzara, which contains an active glucoside uzarin. This is more soluble than digitalin, less toxic than ouabain, and should take equal rank with these two glucosides as a myocardial tonic and stimulant.

Three surgical courses will be given this year at the surgical clinic of the Salpêtrière, Paris, under the direction of Gosset and Loewy. Each course is of one week, and they will begin on May 14th, June 25th, and Dec. 17th. Practical operations will be performed by those attending, and the number of students is limited to ten. Particulars may be had from the Secrétariat Faculté de Médecine, 12, rue de l'Ecole de Médecine, Paris. An announcement in English of these courses appears in the *Presse Médicale* of April 25th.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Copper Salts in Anæmia.

DISCOVERIES which may have great medical significance were announced at the recent meeting of the Federation of American Societies for Experimental Biology. Dr. E. B. Hart and his colleagues in the department of agricultural chemistry of the University of Wisconsin noticed that while their rats could be cured of anæmia by the ash of liver or lettuce, they could not be cured by any kind of inorganic iron salts. They observed also in the successful ash a bluish tinge suggestive of copper salts. Recollecting the copper content of the respiratory pigment (hæmocyanin) of certain crustacea they proceeded to test a diet in which ferric chloride was supplemented by copper sulphate. Striking cures resulted. It is suggested that copper may be necessary as a catalyser in the formation of hæmoglobin. At any rate copper is now to be used experimentally by certain of the larger hospitals in the diet of patients suffering from anæmia.

That Congo red is a "non-specific antitoxin" is claimed by Prof. P. J. Hanzlik and Prof. E. M. Butt, of Leland Stanford University. The property is said to be shared by other colloidal dyes, but Congo red seems to have been the most effective in preserving guinea-pigs, rabbits and pigeons from lethal doses of botulinus and diphtheria toxins.

Research Defence.

The new quarterly journal for laymen, entitled *Medical Progress*, is published by the American Association for Medical Progress, which corresponds very closely with the British Research Defence Society. The articles in the first number, all commendably serious and thorough, include one by Dr. Gladys H. Dick on the Control of Scarlet Fever, and a signed article by Dr. Benjamin C. Gruenberg, who is managing director of the Association, as well as Editor of its journal. The Journal will make its appeal to a more intelligent and educated public than that for which *Hygeia* has catered so successfully, but it will have to give more matter before it will gain a large circulation at 25 cents per number. The Association itself has already done a great deal of useful work. It was founded in the belief that the danger of anti-scientific sentiment in the United States, particularly as it affects public health and care of the sick, lies not merely in widespread ignorance regarding scientific discoveries or methods, but in various efforts to discredit the scientific method in medical research and in public health procedure. This hostility exploits the ignorance of the masses and panders to their prejudices. The result is that medical standards are lowered. During the last year the Association has investigated the three groups of cases in which serious reactions followed the administration of diphtheria toxin-antitoxin. Another praiseworthy action of the Association has been an effort to locate and, when necessary, to care for the survivors of those volunteers who risked their lives under Major Walter Reed and his associates in the critical experiments which revealed the ætiology of yellow fever. This work has been done in connexion with the Copeland-Wainwright Bill, which seeks to make Congress responsible for such care in the future. The Association has its headquarters among the member societies of the National Health Council at 370, Seventh-avenue, New York City.

Schistosome Dermatitis.

Last summer, when Prof. Cort of the Johns Hopkins School of Hygiene was collecting snails at the University of Michigan Biological Station on Lake Douglas, he made a painful but quite interesting discovery. He had a number of catches which he brought home in a bucket containing about ten inches of water, and subsequently he removed the snails two or three at a time from this bucket in order to assign them eac to its proper species. In this leisurely process hi left hand was brought into frequent contact with th water; "after about ten minutes a severe prickling sensation, resembling the bites of small insects, wa felt on the back and sides of the wrist." In spite o the immediate application of soap and alcohol pruriginous papular dermatitis developed. Th papules became pustular after 48 hours, and th discomfort was considerable, and lasted altogethe for five days. Similar cases of dermatitis had bee noted throughout the district for a number of years but Dr. Cort apparently was the first helminthologis to be attacked. The offending cercariæ were dul isolated, and made to repeat their performance o Dr. Cort and others. It is interesting that tw human volunteers proved uninteresting to the sam cercariæ that invaded Dr. Cort and others of hi friends avidly enough. An account of Dr. Cort' experiments appears in the *Journal of the America Medical Association* for March 31st.

The New Coolidge Tube.

Dr. W. D. Coolidge announces the successfu completion of an X ray tube which operates at 900,00 volts and discharges a stream of electrons with velocity of 175,000 miles per second. Finding himse unable to build a single tube for more than 300,00 volts, owing to the "cold cathode" effect, Dr. Coolidg designed a cascade arrangement by which the ra are speeded up from one tube to another. Th present achievement does not mark the limit possible attainment by any means. "We expect, says the inventor, "to find that a high-voltag positive ray tube can be constructed along the gener lines of the multi-sectional cathode ray tube. I this case, we should need, according to Rutherfor about eight million volts to produce positive ra having the energy of the highest velocity alpha ra from radium." It is too early to forecast the ther peutic possibilities of the new invention, but radiol gists will have no difficulty in believing that they a likely soon to have a new and powerful instrument their disposal.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 5TH, 1928.

Notifications.—The following cases of infectic disease were notified during the week:—Small-po 321 (last week 376); scarlet fever, 1591; diphtheri 1097; enteric fever, 63; pneumonia, 1323; puerper fever, 49; puerperal pyrexia, 108; cerebro-spin fever, 12; acute poliomyelitis, 9; acute poli encephalitis, 1; encephalitis lethargica, 29; dysenter 16; ophthalmia neonatorum, 111. No case cholera, plague, or typhus fever was notified duri the week.

Cases of small-pox were notified from the following counties: London, 27 (distributed over four metropolit boroughs, Wandsworth 10, Lambeth and Poplar 8 ea Stepney 1); Bedford, 8; Berks, 1; Chester, 1; Derby, Durham, 58; Essex, 2; Gloucester, 5; Lancaster, 2 Leicester, 1; Lincoln, parts of Holland, 8; parts of Linds 4; Norfolk, 1; Northumberland, 9; Nottingham, 10; Sc of Peterborough, 1; Southampton, 1; Stafford, 13; Surr 2, Sussex West, 1; Warwick, 2; Yorks, North Riding, West Riding, 88; Glamorgan, 20; Monmouth, 23.

The number of patients in the Infectious Hospitals the Metropolitan Asylums Board on May 8th–9th was follows: Small-pox, 29 under treatment, 3 under obser tion; scarlet fever, 1550; diphtheria, 2183; enteric fev 34; measles, 1281; whooping-cough, 131; puerperal fev 24 (plus 18 babies); encephalitis lethargica, 68; "ot diseases," 19. At St. Margaret's Hospital there were cases of marasmus and 15 babies (plus 11 mothers) w ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, includ London, there was one death from small-pox, 7 from enteric fever, 89 (52) from measles, 9 (3) fr scarlet fever, 51 (9) from whooping-cough, 33 from diphtheria, 44 (9) from diarrhœa and enter

nder two years, and 73 (19) from influenza. The gures in parentheses are those for London itself.

The death provisionally classified to small-pox was signed to Bradford. It was, we understand from Dr. J. Buchan, that of a man, 51 years of age, vaccinated in fancy, who was admitted to the Small-pox Hospital m the Bradford Municipal General Hospital. The small-x was of a mild character, the primary cause of death ing pernicious anæmia. The fatal cases of enteric fever tside London occurred at Walsall (2), Bath, Manchester, ull, Middlesbrough, each one. Of the 37 fatal cases of easles outside London 4 were returned from Sheffield and each from West Ham, Liverpool, and Manchester; while e figures in Edinburgh, Glasgow, and Dublin for the same ek were 9, 4, and 6. Of the 42 fatal cases of whooping-ugh outside London 10 were reported from Liverpool d 8 from Birmingham.

e number of stillbirths registered during the ek was 315 in the great towns, including 57 in ndon.

"Audi alteram partem."

A SIMPLE HOOKWORM LARVICIDE.

To the Editor of THE LANCET.

SIR,—In an annotation under this heading in E LANCET of April 21st there is quoted work by . W. O. Fischer, Superintendent of Research in the nd Mines Laboratory, on the effect of common salt i destroying hookworm larvæ. Fischer's paper elf contains no references, yet it is interesting to n back 22 years and reconsider one which might well ve been given, in the shape of work by Lambinet i the Liège coal-mines,[1] reported on by Kuborn at t Academy's session on April 28th, 1906. This ort dealt with just the matters considered by cher and reached conclusions which seem to be se to which he too has come. Manouvriez, of lenciennes, had stated that coal-mines with saline ter were not infected with ankylostomes while se with fresh water were. Lambinet set himself determine, by careful and controlled experiments, ether common salt could be used as a disinfectant mines. He showed that in 2 per cent. salt solution athed hookworm larvæ survived a month, in per cent. 10 to 20 days, in 10 per cent. they died our or five days, in 15 per cent. a few survived for hours, and in 30 per cent. death was rapid. Again, ng parallel sets of cultures, but moistening one h salt solution and the other with water, Lambinet's lts coincided with those of Hayo Bruns, of Berlin, that 3 per cent. salt solution was the lowest con-tration which prevented development to the infec-stage. Finally no development occurred in a stool in eggs, but covered with salt, and to cover stools h this cheap material constituted Lambinet's gestion for the eradication of hookworm infection n mines. Lambinet's work was not received with husiasm; it was altogether too simple for his lience, as good methods so often are. It at all nts seems to map out with sufficient precision the und which Fischer has explored 22 years later. incident is illuminating, as being one of a number recent instances which show that much which is not known concerning hookworm infection by ne of us who are working on the subject was definitely accurately determined even more than 22 years .

I am, Sir, yours faithfully,

aling, May 4th, 1928. CLAYTON LANE.

** Colonel Clayton Lane's letter is a reminder that possess no convenient résumé in a single cover of immense mass of recent knowledge regarding kworm disease in various parts of the world.—ED. L.

THE TREATMENT OF ULCERATIVE COLITIS.

To the Editor of THE LANCET.

SIR,—The report of the discussion on Ulcerative Colitis at the Harveian Society, and your leading article thereon of April 28th, give such a pessimistic view of the results of treatment in this disease that I feel called upon to add my protest to those of Dr. Hurst and Dr. Ryle, as in my opinion it is quite erroneous to believe that ulcerative colitis is anything like as incurable or fatal a disease as these reports purport to show. It has been my lot to see and treat a large number of such cases, and apart from those seen in private, there are never less than three or four cases at a time in St. Mark's Hospital. The total number of such cases of which I have recent records is 130 of various degrees of severity, with 13 deaths; this gives a mortality of 10 per cent.

My experience has been that about 40 per cent. of patients recover without operative interference. Suitable medication, dietary, and lavage of the colon, combined with serum injections and zinc ionisation, prove sufficient to restore the mucous membrane to a normal condition. The patient is examined periodically with the sigmoidoscope and treatment continued until no signs of ulceration can be seen. Although I have seen very good results from the injection of antidysenteric serum in a few cases, it has completely failed to have any influence on the disease in the majority. The other 60 per cent. of cases have been treated by appendicostomy, either because they were very bad cases to begin with or because non-operative treatment had been given a fair trial and failed. It follows that all the more serious cases have been operated upon.

Of the 130 cases treated: 51 were treated without operation; 79 were treated by appendicostomy.

Of the 51 cases: 27 were definitely cured; 23 were improved and ceased to attend, but cannot be claimed as cures, as they were not examined after they said they were well; 1 died.

Of the 79 cases treated by appendicostomy: 59 were definitely cured; 12 died; 8 improved.

The total mortality therefore was only 10 per cent.

The most troublesome feature of the disease is its marked tendency to recur, but it eventually dies out, and the vast majority of patients are completely restored to health.

One of the commonest errors in treatment is that so often the patient is put upon a diet with insufficient nourishment. Ulcerative colitis is a very exhausting disease, and if recovery is to take place the patient must be well fed. As in the case of tubercle, he requires an increased amount of intake to make up for the increased loss. As a rule, the diet is reduced rather than increased. My experience has been that a full diet should be given. The difference between the residue of a mutton cutlet and a glass of milk by the time it reaches the colon is negligible as regards any effect upon the ulcerated surface. I am constantly seeing cases of ulcerative colitis who, to all intents and purposes, are being carefully starved. It is just as absurd to suppose that a patient with this disease can recover on a starvation diet, as that a patient with phthisis could do so. The improvement that results from feeding such patients on full diet is spectacular. I can almost hear some of my medical colleagues saying, "How ridiculous! A patient with ulcerative colitis cannot digest ordinary food," but why not? Digestion does not take place in the colon, and in these days there are many aids to digestion.

About a year ago I had sent up to me from the country a poor curate who was supposed to be dying from ulcerative colitis. He had had an appendicostomy performed, but was getting no better. He had been ill for 18 months and weighed 5½ st. I had not seen him until he arrived on a stretcher in the nursing home. I found he was reduced to skin and bone, but the sigmoidoscope revealed a normal colon with no ulceration at all. I found he had been fed on small quantities of milk and

Benger's food and the total quantity would not have kept two ordinary sized cats in health. I put him on a full diet gradually, with pepsin and pancreatin to assist his digestion, and in six weeks he put on 3 st. in weight, an average of half a stone a week, and is now perfectly well.

I am, Sir, yours faithfully,

J. P. LOCKHART-MUMMERY, F.R.C.S.

London, W., May 9th, 1928.

HAS THE CAMPAIGN AGAINST VENEREAL DISEASE BEEN A FAILURE?

To the Editor of THE LANCET.

SIR,—In your issue of May 5th Dr. E. Graham Little discusses the merits of compulsory measures in dealing with venereal disease and refers to the legislation promoted recently by the Edinburgh Corporation. I have no desire to enter into a discussion on the merits of the Edinburgh Corporation Bill, but I think it advisable to correct the mis-statements in the latter part of Dr. Little's letter.

The meeting of the Edinburgh division of the British Medical Association, to which he refers, was not called by the promoters of the Bill. Whipping was not indulged in. The meeting was called by the secretary of the division in the usual way, and each member of the division was asked on the billet to bring with him to the meeting the statement by the corporation which had been issued to every medical practitioner in Edinburgh some weeks previously. The meeting was a large one for a divisional meeting, when one considers that the average attendance at such meetings is about 30, while some 60 members attended this meeting. The provisions of the Bill were freely and frankly discussed and every member present was in favour of some action being taken to deal with defaulters. The minority of 11 were in favour of the Bill in so far as the powers vested in the medical officer of health were restricted to information given by medical practitioners only. No motion was proposed, by any member present, against the Bill. In view of the findings of the meeting, the number of members present, and the fact that this is the body which represents the medical profession in the city, the promoters of the Bill were justified in claiming that representative medical opinion in Edinburgh was in favour of some measure of legislation to enable venereal diseases to be dealt with more effectively.

With regard to the opinion of the medical profession in other areas of Scotland, I understand that in Lanarkshire 95 per cent. of the medical men are in favour of a much more drastic measure which has beeen drafted by the V.D officer of the county. Each member of the profession has been circularised and signified in writing his support of a measure on similar lines to that which is being promoted by the Glasgow Corporation.—I am, Sir, yours faithfully,

DAVID LEES.

The Royal Infirmary, Edinburgh, May 8th, 1928.

To the Editor of THE LANCET.

SIR,—The correspondence evoked by my letter of April 21st shows that the subject is one of widespread interest. May I, therefore, comment on some of the points raised. It would seem that my main contentions are admitted. These briefly, are that gonorrhœa, particularly in women, is being inadequately handled, that the results are not to our credit, and that a great increase in in-patient accommodation is required if we are to get anything like even the moderately good results we have obtained in the treatment of syphilis.

It is heartening to find Dr. Burke championing the cause of the V.D. clinics run from premises specially equipped and staffed for the purpose. There is an official tendency to depreciate such clinics on the assumption that patients do not care to be seen attending them, but prefer to go to a department of a general hospital, thus hiding the reason for the visits. Undoubtedly there are such people. Equal there are just as many who think that the special clin is better because it is special. Both classes should considered. At the Lock Hospital we have as mar as we can handle who come for their entire treatmen We find, however, that there are quite a considerab number who come once for a diagnosis, attend son clinic, less labelled or more convenient, for the treatment, and return to the Lock Hospital for the final tests for cure—thus making the best of bot worlds. Clinics attached to the great general hospita have many obvious advantages. They have o weakness, however, which is deplorable, and whi should be remedied; they do not provide bed accon modation in just proportion to the grants given the since the antivenereal campaign of 1917 was started

This present-day interest in venereal disease is n a new thing. History has a habit of repeating itse It is a mistake to think that it is only since the Gre War that venereal diseases have become so prevalen During the mid-Victorian period these diseases we rampant throughout England. This is not surprisi when one remembers that gleet was then consider non-contagious and syphilis was treated by a tw month course of mercury pills. A census taken Acton at Paget's out-patient clinic at St. Bartholomew showed that over 50 per cent. of his patients we venereal. At Guy's the proportion was 43 per cen whilst at the Royal Free it was over 60 per cer Dr. Burke will be interested to note that in Manchest and Salford, with a population of 390,000, there we about 3500 venereal cases treated in one year (186 In those pre-Listerian days pressure on hospital be was not as great as now, and the accommodation f venereal cases was therefore more generous. At S Bartholomew's,[1] for instance, there were 75 beds, Guy's 58, at the Royal Free 26, at the Middlesex 2 at the London 15, and so on. Altogether in Lond hospitals in 1870 there were 374 beds for venere cases, when the population was 3,000,000. Now th are about 200 odd for 7,000,000. The hospitals we receiving no grants then. They are receiving lar ones now. Further comment is unnecessary.

Dr. Graham Little's courteous letter in your iss of May 5th, p. 932, deserves careful considerati because he was the main opponent of the Edinbur Corporation Bill which has just been thrown o Personally I think he was wrong in opposing t second reading, because the action of Parliament l created a feeling of grievance in Scotland. If t Corporation of Glasgow persists, in spite of the fate the Edinburgh Bill, in presenting theirs, I hope he v help to give it a chance of better ventilation. T more discussion there is on these subjects, the more t public will be educated as to their importance.

I have no ambition whatever to see any coloura imitation of the C.D. Acts of 1864–70 re-enacted England. The working of those Acts at that ti depended largely for their success on the staff of Lock Hospital for Women, Mr. James Lane, and Gascoyne. I have still vivid memories of conver tions with the late Mr. Ernest Lane in which recounted how his uncle was publicly vituperat how his letter-box was crammed daily with virulen abusive letters from religious fanatics who said was making vice safe, and how the agitators for rep mentally transferred the moral guilt attached to diseases from the shoulders of the patients to thos the people treating them. I take off my hat to stalwarts in Scotland prepared to face, possi similar treatment. I admire but do not wish emulate.

Reference to treatment was no part of my orig letter, but, as it has been raised, may I be permit two comments. Mr. Peart has advocated vasotom acute gonorrhœa. I have no use whatever for form of treatment in the acute stage. My experience of it dates back some six years ago, w Dr. C. F. Searle, of Cambridge, sent me a patient

[1] Acton on Prostitution, London, 1870, 2nd ed., pp. 81–8

had been thus handled by an enterprising American surgeon. As a result the right testis became gangrenous and had to be removed. Spermatozoa also disappeared from the semen, and there was persistent prostatic neuralgia. The original gonorrhœa was cured, but the price—sterility and loss of one testicle—struck me as excessive. Even in chronic vesiculitis the procedure is not without risks. In acute disease it is, in my opinion, unjustifiable.

Finally, a word about diathermy, and the belief of Dr. Cumberbatch and Dr. Robinson, that it would solve the woman's problem. I have used this method of treatment for five years at the Hospital for Women, Harrow-road. Before doing so, I sat at the feet of Dr. Cumberbatch and Dr. Robinson for some months. I have since sent most of my house surgeons at that hospital to St. Bartholomew's, where they have been shown, most courteously, all the details of treatment. I have described the treatment in my book [2] and given them all the credit due to a definite advance. I have seen individual cases of Dr. Cumberbatch and Dr. Robinson, and confirmed the claim of cure made by them. I have had cases of my own which were brilliant successes under this treatment. And yet I have not found diathermy quite the panacea they believe it to be. Perhaps it is because I get cases that are more serious, cases complicated by such things as syphilis, or pregnancy, suburethral abscess, bartholinitis, or acute salpingitis. If diathermy always gave in cases treated by others the excellent results obtained by Dr. Cumberbatch and Dr. Robinson in their cases the cure of gonorrhœa in women would be very much simplified. But like every other form of treatment it has its failures as well as its successes. If it did away with the necessity for in-patient treatment it would be not only an incalculable boon to suffering humanity but also an enormous saving to the nation in the matter of upkeep. Unfortunately it does not do so. I only wish it did.

I am, Sir, yours faithfully,

J. JOHNSTON ABRAHAM.

Harley-street, W., May 6th, 1928.

PULMONARY ATHEROMA.

To the Editor of THE LANCET.

SIR,—The leading article on this subject in your last issue possesses great interest for me, as it recalls a case bearing on this topic recorded by me in 1903, in vol. xxxvi., p. 218, of the Clinical Society's *Transactions*. A girl, aged 21, had been shown by me to the Society in 1901, as a case of congenital morbus cordis, and this view was accepted by most members who had examined the patient. The clinical features were dyspnœa, cyanosis, and attacks of cardiac pain, the latter dating from childhood. There was no clubbing of fingers, and no history of rheumatism or syphilis. The girl was very small for her age, but otherwise fairly well formed. The physical signs indicated great enlargement of the right heart. With the exception of a faint diastolic murmur occasionally audible over the pulmonary artery, where the second sound was very loud as in all areas, there were no adventitious sounds. A few months later the patient began to suffer from nausea, vomiting, and increased dyspnœa. On admission the liver was enlarged and tender, and the ankles were œdematous. Shortly afterwards the patient had a sudden fit of dyspnœa with great lividity and died in a few minutes. At the autopsy the heart weighed 17 oz., and there was great hypertrophy and dilatation of the right side. A few small granulations were seen at the cusps of the pulmonary valves, but there was no further valvular defect. The pulmonary artery showed extreme atheromatous changes in its trunk, extending down to the finest branches in the lungs. The lungs were quite healthy.

This case closely resembles those described by Mrs. Coombs, Clarke, Hadfield, and Todd. But though the enlargement of the right heart was considerable, cyanosis at first was relatively slight. From the history of the symptoms going back to childhood one must conclude that the disease started during intra-uterine life. Dr. Coombs and his colleagues are inclined to attribute the pulmonary lesions to an inborn defect of the pulmonary arterial walls. I would suggest that the arterial disease is more likely to have been due to a toxic condition during fœtal life.

The part played by pregnancy in the production of toxæmic conditions affecting the mother is now well recognised, and it would not be strange if the fœtus should suffer, too, at times.

I am, Sir, yours faithfully,

PERCY KIDD.

Montagu-street, Portman-square, W., May 15th, 1928.

[2] Lectures on Gonorrhœa in Women and Children. Heinemann. 1924.

INJECTION TREATMENT OF VARICOSE VEINS.

To the Editor of THE LANCET.

SIR,—We have read with pleasure the instructive letters of correspondents in your issues of April 28th and May 5th, and in reply would make the following observations.

1. The recumbent position is a difficult one in which to insert the needle into the vein which is collapsed. If the patient stand for the insertion and then lie down, this movement may dislodge the needle from the lumen.

2. If the vein be collapsed at the time of insertion of the needle its walls may be transfixed by the needle and the subsequent injection be paravenous, a complication which all your correspondents rightly endeavour to avoid.

3. Since injections into the dilated vein are successful in practice, such contact of solution and endothelium as is necessary must in fact occur.

4. Localised digital pressure after puncture is not sufficient to prevent extravasation. An oblique entry of the needle through sound skin is also necessary. An analogy is suggested from blood transfusion practice, where little bleeding occurs after withdrawing the needle from the donor's vein, provided that an oblique entry was first made.

5. Drs. K. M. and C. J. Cellan-Jones criticise our dose of 15 c.cm. of quinine sclerosing fluid. May we point out that this figure, like that of 5 c.cm. for a single injection, represents the maximum, just as 0·5 c.cm. is the minimum. We agree that in practice the operator must feel his way, and when dealing with a patient of unknown susceptibility he must commence with one or two injections of 1 c.cm., which are later increased in the light of experience.

We believe it to be in general true that the extent of thrombosis varies directly with the amount of fluid injected, although exceptions to the rule not uncommonly occur.

We are, Sir, yours faithfully,

RODNEY MAINGOT.
C. HOPE CARLTON.

May 8th, 1928.

INJECTION FOR INTERNAL HÆMORRHOIDS.

To the Editor of THE LANCET.

SIR,—In an article dealing with this subject in your issue of March 17th Mr. A. S. Morley referred appreciatively to the work of Dr. C. E. Blanchard, the eminent proctologist of Youngstown, Ohio. It may interest your readers to know that Dr. Blanchard is visiting London early in July, and will be prepared to demonstrate his technique during his short stay here.

I am, Sir, yours faithfully,

FRANK COLLIE.

Inverness Mansions, W., May 9th, 1928.

EAST END MATERNITY HOSPITAL.—The annual report records that this hospital maintains its "wonderful record of low maternal mortality," only one death having occurred among 2061 patients.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Health Insurance Bill.

THE National Health Insurance Bill was further considered by Standing Committee C of the House of Commons on May 1st, Sir R. SANDERS in the chair.

Clause 6: Separate Valuation.

The Committee resumed consideration of an amendment to Clause 6, moved by Mr. JOHNSTON, providing that where a society without branches had been approved for more than one national area a separate valuation might be made in respect of each national area.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that this was a very difficult and technical matter and one with regard to which he thought the Committee would be well advised to take the advice of experts who had given a good deal of consideration to it. Clause 6 gave effect to the advice of the Royal Commission and if they began to encourage a separate valuation they would have all the difficulties of transfer of a member from one country to another. The cost of separate valuations would be very great indeed.

Insurance Benefits in Northern Ireland.

Mr. JOHNSTON said that whereas the Royal Commission's Report was dated 1926, the figures on which he had based his amendment related to 1927. In Northern Ireland to-day the doctors were paid 2*s*. 6*d*. for every certificate. To that extent there was an inducement to find ways and means of continuing this system of perpetual ill-health and disablement in Northern Ireland, whereas in England, Scotland, and Wales the doctors were paid on the basis of a capitation grant. The results were amazing. No one would argue that the real ill-health and disablement in Northern Ireland were three times worse than in England, Scotland, and Wales, and yet the figures for 1927 gave some most astounding results. Take the Prudential Society's figures. For men the sickness benefit averaged in England 16*s*. 11*d*. per member per annum, in Scotland 15*s*. 7*d*., and in Northern Ireland 31*s* 6*d*. In regard to disablement benefit the figures for men in England were 8*s*. 9*d*. and in Scotland 9*s*., but in Northern Ireland the amount was 16*s*. 11*d*. The disablement benefit for women in England cost 9*s*. 8*d*., in Scotland 8*s*. 1*d*., and in Northern Ireland 22*s*. 8*d*. per member. These figures of the Prudential Society were borne out by those of the National Amalgamated Approved Society, the Liverpool Victoria Friendly Society, the Royal Liver Friendly Society, the Royal Coöperative Society, and the City of Glasgow Friendly Society.

Mr. CHAMBERLAIN (Minister of Health): There is no dispute about the figures.

Mr. JOHNSTON said he was glad to hear that, but what was to be done about it. He would be prepared to have words inserted providing that if the Minister was satisfied that there should be a separate valuation such a valuation should be granted. The Committee ought to take the present opportunity of speeding up greater efficiency in the health administration and medical service of Northern Ireland. Otherwise they would have members in Northern Ireland abstracting two or three times more from the funds of the approved societies than members in the rest of the country.

Dr. VERNON DAVIES: Will the hon. Member explain to the Committee whether he has formed any opinion as to why the figures are higher in Northern Ireland?

Mr. JOHNSTON said that his information was that one of the reasons was the different method by which the doctors in Northern Ireland approached the question. Certain test examinations had taken place when doctors had been specially deputed to make examinations of some of these repeated beneficiaries in Northern Ireland, and it had been discovered that the people concerned ought not to be beneficiaries, and would not continue to be so if they had been medically tested by the same standards by which approved persons were tested in England, Scotland, and Wales.

Colonel SINCLAIR, who said he was the only member of the Committee from Northern Ireland, said that the amendment would practically compel Northern Ireland at the present time to establish an health insurance scheme of a nature similar to that which existed in Great Britain. That would be an extremely complicated business, because the dispensary system which had existed in Northern Ireland for several generations would require to be remodelled in some way to bring it into harmony with the establishment of medical benefits in England and Scotland. The Minister for Home Affairs in Northern Ireland appointed a Commission to look into the affairs of poor-law administration in Northern Ireland, and a valuable report was furnished to the Governor of Northern Ireland at the end of last year. The Cabinet had not had time to consider and draft a scheme of reform of local government services of which the dispensary system would form an integral part. He would be sorry if the adoption of this amendment more or less stampeded the Government of Northern Ireland into hasty legislation, which would again have to be remodelled when the larger question of local government services came to be considered as a whole. He freely admitted that the figures submitted by Mr. Johnston were disquieting. There was need for an endeavour to improve matters so that this startling disparity might not recur. The Minister of Labour in Northern Ireland acted for the Ministry of Health and he had adopted a medical referee system of which the health services were availing themselves freely. The certification system in Northern Ireland left something to be desired, but the medical referee system now in force would soon help to correct any alleged irregularities of certification, and he had no doubt that when the next audit was reached a very substantial difference would be recorded in the amount chargeable per person on the Insurance Fund. Northern Ireland was far too small an area to support a National Health Insurance system of its own. The difficulty was that in Northern Ireland certification only was asked from the doctor; he was not required to give treatment. Therefore it was not easy to compare the system which prevailed in Northern Ireland with that of Great Britain. The dispensary system in Northern Ireland suited admirably the large agricultural areas and was not so much availed of in the industrial areas.

Mr. RHYS DAVIES asked the Minister of Health whether it would be possible to negotiate with the Government of Northern Ireland to put the administration of medical benefit on the same footing as it was in England, Scotland and Wales; and further, whether it was possible for a society to make a branch of the Northern Ireland members without the provision mentioned in Mr. Johnston's amendment.

Mr. CHAMBERLAIN said with regard to the second part of Mr. Rhys Davies's question he thought there was such a power under Section 39 of the National Health Insurance Act 1924. As to the figures quoted by Mr. Johnston, the Committee must not only consider the proportion of the figures; they must consider the total amounts in question. He (Mr. Chamberlain) thought that the reason why no action had been taken already in this matter was that it was comparatively trivial. The Prudential Society, for example, had a membership of 1,500,000, but had only about 30,000 members in Northern Ireland. There were local difficulties in Northern Ireland which would make it almost impossible for them to make the change suggested at the moment, although he did not despair of seeing it done in the future. In view of this explanation he hoped the amendment would be withdrawn.

Mr. BROAD said he hoped that the Committee would have some clearer indication than had been given that before this Bill became an Act of Parliament the Minister of Health intended to introduce such an amendment as would deal effectively with this matter and put an end to these abuses. He thought the people of Northern Ireland and those responsible as well as the medical profession ought to feel ashamed of themselves and ought to make their own propositions.

Dr. VERNON DAVIES said he did not think the Committee quite appreciated the peculiar psychology of the Irish people. He had never met any people who were more afraid of sickness or pain. It was quite possible that people in Northern Ireland went to a doctor far oftener than people in England. The doctors might be acting quite fairly, but in any case they would get a higher number of claims from Irish people than from the English, Scottish, or Welsh.

Mr. MELLER said he would like to accentuate the view which had been expressed regarding the inadequacy of the arrangements in Northern Ireland through the absence of medical benefit. The system of certification in Northern Ireland was an incentive to people to get certificates. There was no medical service in the strict sense of the term. What he understood to be the real difficulty in Northern Ireland was that the people had no desire to get bottles of medicine, but they desired to have cash, and so long as that was obtainable there was not the slightest desire on the part to recover, nor did he think perhaps, having regard to some of the medical men he had come across in Northern Ireland, that their medicines would often shorten an illness. He hoped that discussion would bring home to the Government of Northern Ireland that something had got to be done.

The amendment was negatived by 26 votes to 12.

The Committee adjourned.

The Bill was further considered in Standing Committee on May 3rd, Sir R. SANDERS in the chair.

Clause 14: Surplus Funds of Approved Societies.

On Clause 14, which deals with the disposal of surplus nds of approved societies, and lays it down that any heme may provide for allocating out of the disposable rplus sums for donations of an eleemosynary character hospitals and similar charitable institutions.

Sir T. DAVIES moved to include the words "or for the pport of district nurses." He said he thought everyone uld agree that the additional benefit which this endment would give would be valued all over the country.

Mr. RHYS DAVIES said there would be strong opposition the money of the approved societies being used for the rpose suggested. He could not understand hon. Members the Conservative side of the Committee. They supported e Chancellor of the Exchequer in reducing the State ant under the Economy Act and they now came to at Committee and sought to insert amendments with e object of spending money which could not be found thin the scheme at all. If they were to provide nursing eatment they would have to do it with money that ought go direct into the pockets of the insured person.

Mr. CHAMBERLAIN said that Mr. Rhys Davies's remarks out the Economy Act were entirely irrelevant. The vernment were under the impression that the words similar charitable institutions" would cover nursing sociations, but as some doubt had been raised about it saw no reason why he should not accept the amendment.

Dr. VERNON DAVIES said he was not quite sure whether n. Members understood the distinction between district rses and nurses. District nurses visited patients once or ice a day only. They were very often run as charitable stitutions supported by the public, and he saw no reason y approved societies should not be allowed to contribute little towards their funds. All insured persons had a im on the services of these nurses, whether they paid ything or not; they simply went on the recommendation of e doctor, and it was quite right that they should do so. The amendment was agreed to.

X Ray Examinations in Cases of Fracture.

Dr. WATTS moved an amendment to provide for X ray aminations in cases of fracture, or suspected fracture. e said that the amendment was moved both in the interests the insured person and for the protection of the panel ctor. In recent years it had become absolutely necessary almost every case of fracture to have an X ray photograph. several cases before the courts recently it had been held at failure on the part of a doctor to get an X ray otograph rendered him liable for an action for damages the event of anything going wrong with the fracture. panel doctor had no means of getting an X ray photograph less he paid for it out of his own pocket, and with the all remuneration which he got under the Act that would a hardship. There was a good deal of feeling among rious insurance committees in different parts of the untry about the necessity for this additional benefit, d he had been asked by the Cheshire Insurance Committee ongst others to bring the question forward. The cost uld be trifling.

Sir KINGSLEY WOOD said he was sure that the Committee d every sympathy with the object which Dr. Watts had view, and anything that could be done to secure proper amination in such cases as those which had been entioned would be done provided that the finances of the cieties permitted it. He was afraid, however, that this endment could not appropriately be inserted in this rticular clause, which simply gave an opportunity for cieties within their disposable surplus to make occasional bscriptions to hospitals or other charitable institutions. cieties could make an additional gift to institutions aking a specialty of X ray treatment, but phraseology of e kind suggested in the amendment could not be put in is part of the Bill.

Dr. VERNON DAVIES: I understand that insured patients e entitled to the best medical attendance, and that that is e of their rights under the Act.

Sir KINGSLEY WOOD: They are entitled to the attendance entioned in the Act.

Dr. VERNON DAVIES said that insured persons were titled to anything which came within the competence of ordinary medical practitioner. If a doctor did not make X ray examination he might miss the fracture altogether. a doctor was not certain, how could he give the best illed attention?

Sir KINGSLEY WOOD said that if the Committee desired discuss whether this matter came within the scope of e ordinary medical practitioner or not they must deal th that point in another part of the Bill.

Dr. WATTS said that, having regard to the undertaking ven by the Parliamentary Secretary to the Ministry of alth that this matter should be considered when the mmittee reached the First Schedule, he would withdraw s amendment.

The amendment was by leave withdrawn.

The Administration of Additional Benefits.

Dr. VERNON DAVIES moved an amendment to the effect that "additional benefits shall be administered by the society or branch of which the persons entitled to the benefits are members, except where the benefits are in the nature of medical benefits." He said that this was apparently a simple and harmless proposition, but those who knew anything about the past history of the National Health Insurance Act knew that it was a very controversial subject. He had retired from medical practice and had not the slightest interest one way or the other in the medical profession, so that he could speak for that profession in a more or less unbiased way. Before the National Health Insurance Act of 1911 the friendly societies had formulated a scheme by which their members were enabled to get medical treatment and attendance during sickness by the payment of small subscriptions annually to the committee of the society who in turn appointed a doctor to look after these patients; that was to say, the doctor was appointed by a lay committee at, as a rule, a certain definite contract rate which was about 4*s.* a year. This scheme went on for years and the lay committees formed the idea that it was a perfectly reasonable the proper thing that they should be able to employ or engage medical men. When the national insurance scheme was broached the matter was brought to a head because the medical profession as a whole had formed the opinion that, being members of a learned profession, it was perhaps not conducive either to their dignity or to their position that they should be managed by a committee of lay people, particularly when it came to be a matter of medical treatment or benefit. The approved societies, on the other hand, said: "We have been working a scheme like this for some time; the doctors have been our servants: everything has worked satisfactorily, and we see no reason why under a national insurance scheme we should not be allowed to carry on in the same way." That led to a rather bitter and acrimonious fight, and the result was that the State intervened and made definite regulations by which the medical men were not put under the power or authority of the approved societies. He imagined that the approved societies had not been quite able to get over their disappointment and that there was even now perhaps a slight feeling of irritation, he might even say of veiled antagonism, to the medical profession, and they seemed to have developed the idea that that profession were simply out to protect their own interests irrespective of anything else. In his view the whole health insurance scheme rested upon a tripod of which the three legs were the State, the approved societies, and the medical men. If any of these legs was not functioning properly the whole scheme was imperilled. These three parties should be in coöperation, no one of them superior to the others, but all equal and working for the benefit of the insured person. In that way a sound foundation would be laid on which could be built up a superstructure of national health insurance which would be a benefit not only to the country, but to the insured persons themselves. Before the scheme could be competently worked they would have to come to that position. The medical profession had no desire to be superior. They desired to work with the approved societies, but they most definitely would not work under them. Subsection (5) of Section 75 of the National Health Insurance Act, 1924, was as follows:—

> "Additional benefits shall be administered by the society or branch of which the persons entitled to the benefits are members, except that where the benefits are in the nature of medical benefit, they shall be administered by and through the insurance committee."

He maintained that by that subsection the State recognised that the medical men should not in any circumstances be placed under the supervision or control of the approved societies in connexion with medical benefit. He understood that it was now proposed to delete this subsection, and that the view of the Ministry of Health was that it was either unnecessary or unworkable. That was perhaps an arguable position, but the medical profession said that this was a subsection upon which they had relied in the past to prevent the approved societies from administering benefit which was in the nature of medical benefit, and if it were necessary to put in this provision the fact that it had perhaps not worked, or was not workable, was no reason why it should be deleted if the medical profession had the idea that it was a certain safeguard for them. It would appear now as though the approved societies might be able to re-establish the position as far as regarded additional benefit of a specialist or consultant character which they thought was put an end to by the Act of 1911. It might be said that the power of the Minister to make regulations under Subsection (3) of Clause 14 meant that he would make such regulations as would ensure that the point which he (Dr. Davies) was trying to press home would be adequately safeguarded. They all knew, however, that it was not always advisable to legislate too much by

regulation. The regulations made depended absolutely on the personality of the Minister who happened to be in office.

Sir KINGSLEY WOOD: They have to go before Parliament.

Dr. DAVIES said that was so, but the Minister of Health would put the Government Whips on and get the thing through straight away. The putting of any regulation on the Table of the House was thus more or less a farce.

Sir KINGSLEY WOOD said that whatever political party might happen to be in power, if a case could be made against regulations the procedure of the House offered one of the most effective checks which could be devised.

Dr. DAVIES said he contended that the approved societies would really be put in their old position, except for the safeguard of the regulations of the Minister. The acceptance of his amendment would do the Act no harm, it would do the approved societies no harm, and it would be welcomed by the doctors as putting into the Statute something which they thought they ought to have as a safeguard.

Mr. CHAMBERLAIN said that in his endeavour to avoid the difficulties of Section 75 (5) of the existing Act, Dr. Davies was creating fresh difficulties. Section 75 (5) not only said that where the benefits were in the nature of medical benefits they were excluded from the general rule under which additional benefits were administered by the societies, but it said who was to administer benefit of the nature of medical benefit—namely, the insurance committees.

Mr. HARVEY: That is repealed in the Schedule—Subsection (5).

Mr. CHAMBERLAIN said it was repealed, and Dr. Davies wanted to restore it, but he did not restore it in the form in which it stood. He cut out the part which said how the medical benefits were to be administered in the future. Under the existing Act additional benefits in the nature of medical benefit were to be administered by the insurance committees. The hon. Member knew that that was impossible, and he had cut it out, thus leaving him in a difficulty, because he did not say who was to administer the additional benefits which were in the nature of medical benefit. In the absence of any definite instruction it would be interpreted to mean that whoever did administer them the approved societies must not have any share in the administration. Therefore he could not accept the amendment. He agreed with Dr. Davies when he said he was in favour of coöperation between the medical profession, the societies, and the Ministry of Health. If the matter was left to the Minister to provide by regulation under Clause 14(3) that would be a method by which the benefits would be administered. They would be administered by a joint body on which the medical profession and the approved societies were represented. The regulations would have to receive the tacit approval of Parliament, and he thought Dr. Davies might rely on the general good sense and fairness of Parliament, however it might be constituted in the future, to see that none of the contributing elements in this combination was put under the domination of another.

Mr. HARVEY asked if the Minister would give some assurance that it was not contemplated to make regulations that would denude the insurance committees of all their functions.

Mr. CHAMBERLAIN: No.

Mr. HARVEY: The only idea is to make provision which does not now exist for the administration of ophthalmic and dental benefits perhaps by the provision of clinics, or whatever they might be.

Mr. CHAMBERLAIN: Yes.

Dr. DAVIES said that having made his protest he could not press his amendment against the Minister.

The amendment was, by leave, withdrawn.

MINISTRY OF HEALTH VOTE.

On Tuesday, May 15th, the House of Commons went into Committee of Supply on a vote of £13,774,025 for the salaries and expenses of the Ministry of Health. Mr. J. F. HOPE, Chairman of Committees, was in the chair.

Mr. CHAMBERLAIN, Minister of Health, said the estimates showed an increase of nearly £1,000,000 over those of last year. Dealing with housing, he said that the number of slum clearance schemes submitted by local authorities, small as it was, was nevertheless the largest that had ever been before the Ministry of Health in the whole history of the slum question. The existing anomalies connected with slum areas could only be put right by amending legislation, but even if those anomalies were put right he was afraid that the process of slum clearance would be so complicated, slow, and costly that it would never present any hopeful prospect of that wholesale improvement in slum property which they must have if they were really to fulfil their moral obligations in the matter. If a proportion of the houses in the slums were improved so as to give the tenant decent conditions, there was a prospect, however, of maintaining the slum-dweller and his family in health at a rent which they could afford and in a locality where the worker could remain near to his work.

Cancer Research.

A great deal of research had been carried on in rega to cancer which was perhaps the largest single cause mortality. That research had dealt with the causes a treatment of cancer both in this country and abroad. Th had not yet been able to put their finger upon any fact, series of facts, which would allow them to say that they h solved the problem of cancer, very far from it, but all t time they were encroaching upon the field of the unknow all the time they were advancing their knowledge. T Ministry of Health had mapped out a sort of scienti survey of what could be done to-day in the effective trea ment of cancer, taking each part of the body in turn, wi the present state of skill and knowledge, and they h followed that up with a careful and exhaustive inquiry in a large number of cases of cancer and the results of th inquiry had been examined by a Departmental Committ set up at the Ministry of Health about five years ago. Th had also done something to bring into prominence certa methods of treatment which they had ascertained fro information derived from at home and abroad had prov particularly effective in the treatment of cancer. The were methods of radiology—the use of radium itself a so-called X ray therapy. These methods were costly a were not easily adopted by all authorities, but they believ that by proper organisation more effective use could made of the equipment which they actually possesse They were keeping in the closest touch with a great numb of other agencies—the British Empire Cancer Campaig the public health authorities throughout the country, a the local cancer committees working in some of the gre provincial centres. While they could not say that th were even in sight of a cure or of a method of prevention cancer, nevertheless they were on the right path, and o day—no one could say when—they might actually tu the corner and find themselves in the presence of the g which they sought. (Cheers.)

Encephalitis Lethargica.

Encephalitis lethargica was a disease in regard to whi central action was particularly necessary if they were make progress because this disease was fortunately n sufficiently common yet for any hospitals or any priva practitioners to have seen very many cases of it. Duri the past ten years there had been about 1500 cases a ye in this country. The Ministry had instituted an exhausti inquiry into about 3000 cases of sleepy sickness. It h been carried out by Dr. Parsons, one of the officers of t Ministry of Health and the results of the inquiry show that only about 25 per cent. of the cases recovered; abo 35 per cent. died, and the remaining 40 per cent. were mo or less disabled mentally or physically. The valua part of this inquiry was that for the first time they kn what were the proportions of the persons attacked by t disease who recovered, died, or were permanently injur They knew the different forms of injury which suffer from encephalitis lethargica might sustain; they knew h those things proceeded, and they had got for the first ti some inkling of what were the best ways of treating t disease. The inquiry came very opportunely after t passing of the Mental Deficiency Act, because in the lig of the inquiry they might hope that that Act might be p to more effective use. The inquiry disclosed a considera variety of cases, and it must be understood that the tre ment which might be effective and desirable for one c might be quite wrong for another. The Mental Deficie Act would enable them to classify cases and treat th in the best manner. He thought that the popular impress that encephalitis lethargica was tending to decrease v correct, but of course sufficient remained to make it a v serious problem because the effects of the disease w frequently permanent, and a person once affected remai a charge upon the community, perhaps for the rest of life.

Rheumatic Diseases.

There were really two distinct groups of diseases wh come under the heading of rheumatism—acute rheuma fever which so often attacked children and which v frequently associated with heart disease; and chro rheumatism of the joints and muscles which frequen disabled industrial workers. Last year approved socie spent on sickness benefit and medical benefit for rheuma insured persons £5,000,000, and in the same year 5,250,0 weeks' work were lost owing to the incidence of rheumat among insured persons. They calculated that rheumat accounted for one-sixth of the whole industrial invalid of the country.

With regard to rheumatism, he was told that the treatm which afforded the best hope was one of prolonged rest institutions, and the Ministry of Health during the p two or three years had tried to encourage the provision hospital accommodation set apart specially for this purp To-day, for the first time, they had actually got from

500 beds specially ear-marked for the treatment of acute eumatism. As regarded chronic rheumatism, the first thing quired there was advice, because the causes of rheumatism re many and various, and it might, and very frequently d, spring from some local centre of infection. It might the teeth that were wrong, or the tonsils, or the intestinal act. He had heard, only in the last 24 hours, of a gentlean who read an account of the papers that were read at conference held last week in Bath on the subject of eumatism. Reading about these focal centres of infecity, it suddenly occurred to him that possibly there might some connexion between the rheumatic pains from which had suffered for years and the sore-throat which had en a constant trouble to him for the same period. He nt to see his doctor, who told him he had got septic nsils, and that that was the cause of his rheumatism. That s only an illustration of how, in the absence of advice, ople accepted rheumatism as though it were a sort of t of God, which could not be prevented and for which thing could be done; yet, under the advice of the specialist, might be traced to some quite easily removable cause, d the suffering might be almost instantaneously relieved. course, a great deal was being done. In the case of the ildren, there was the school dental service, which employed mething like 600 dentists and was treating about 1,000,000 ildren a year. In the case of the elder insured persons, ere was the dental benefit to which approved societies re now devoting some £3,000,000 a year, with a result ich he hoped would show itself in a lessened demand on the funds in the future from rheumatism, and consent incapacity to work. At present, approved societies re paying about £250,000 a year to two hospitals for the eatment of their patients, and a further £200,000 a year s being devoted to convalescent homes in connexion th which, in some cases, there was now being developed a treatment. But they felt that something more than is was required, and that there were forms of treatment, pecially those connected with radiant heat and light, ich had shown very promising results experimentally, and ich the Ministry desired to see extended for the benefit a larger part of the population. The Red Cross Society s now trying to organise the setting-up of an experimental nic of this kind in London, and as soon as that was ready proposed, by regulation, to authorise approved societies make a contribution to that clinic and to obtain treatment their members there. The committee would realise at the full development of a preventive and curative stem in connexion with rheumatism must mean the penditure of very large sums of money. It might be it in the present financial state of the country it was not ssible to carry on that development as rapidly as they uld wish, but, at any rate, they were at last beginning realise the nature of the disease with which they had cope and to realise the extent to which it was crippling people. As that knowledge became more widespread, thought they would see a willingness to devote to the provement of those conditions whatever money might found necessary.

Maternal Mortality.

The Ministry of Health had now been established for ie years, and one might fairly say that as far as one uld measure the progress of the public health by the neral vital statistics, the record of the Ministry was not satisfactory. The general death-rate in those years had ne down from 14 per 1000 to 12·3, and the infant mortality- e had dropped from 89 to 70 per 1000. But there was e figure which showed no improvement, although it ncerned a very vital subject. That was the figure of ternal mortality. It was a terrible thing to think that day, out of every 250 mothers, one died in childbirth, l that that state of things had persisted for the last 20 rs. That was not really the full measure of the injury at was being done. One must not only remember what ppened to the family when the mother was taken away, t one must think of those other mothers who might not , but who emerged from their confinement permanently ured in their health, their nervous system perhaps ttered, and unable really to fulfil the full duties of mother- od. He felt that the time had come when a great new ort ought to be made—(cheers)—to bring down those res of maternal mortality and to improve the health of se mothers. There were many things they did not w yet about the causes of maternal mortality, but they know something. They knew that these figures per- ed steadily throughout the country, but, nevertheless, y were not universal. There were places where they ld find much lower figures. They would be found in se cases where there was the most careful antenatal l postnatal supervision, and where the people themselves l the greatest opportunities of learning what was necessary preserve their health and the lives of their infants. The nistry of Health was taking up this question very seriously. blic attention has been largely directed to it through the blication of a report on the protection of motherhood drawn up by Dame Janet Campbell, a very distinguished officer of his Department. He was now endeavouring to institute a new inquiry into the causes of maternal mortality. He was trying to enlist in that service the general practitioners throughout the country, as well as the local authorities; and the British Medical Association had assured him that they were deeply interested in the question, and would use all their influence with their members to get them to give every assistance possible to his inquiry. Under this scheme, local medical officers of health would make an inquiry into every case of maternal mortality which occurred, wherever it might be, throughout the country. They would make this inquiry on lines which would be laid down by a committee at the Ministry of Health, on the lines of the Cancer Committee. Their returns would come in quarterly to that Committee, the information would be classified, and the Committee would draw what conclusions they found it possible to draw from the information obtained. All that information would then go back again to the local authorities, and would be made known to those responsible for the conduct of the infant welfare centres and the maternity hospitals. He was also setting up a committee to inquire into the whole position of midwives; into their status, training, and remuneration. After all, the success or failure of any efforts they made to improve the conditions of childbirth in the country must largely depend on the midwives, on whom a great responsibility rested. Midwifery was a hard and arduous profession; it was not a well-paid profession; and if they were to get the class of women they wanted to enter that profession—educated, humane, sympathetic, earnest, enthusiastic—they must make the conditions of the profession such as would attract the right class of people. Once again he must warn the Committee that all these efforts would cost money. Money would be needed to provide more accommodation, and for making conditions better for the people who were carrying on the health services, if they were really to make progress. If they could indicate with any confidence to the people of this country what were the precautions necessary to take if they were to remove this menace from their midst he could not believe that the national conscience would allow the lives of mothers to be sacrificed merely for the sake of a few extra thousands of pounds. (Cheers.)

An amendment to reduce the vote by £100, moved by Mr. GROVES, was rejected by 209 votes to 99—majority 110.

CHIROPODISTS (REGISTRATION) BILL.

The text of the Chiropodists (Registration) Bill, which has been introduced in the House of Lords by Viscount NOVAR, has now been published. The Bill sets up a Board to be known as the British Chiropody Board, who will be charged with admitting chiropodists to the Register to be kept under the Act, Subsection (4) of Clause 5 (which describes the persons who are entitled to be registered) provides that nothing in the section shall operate to prevent the practice of chiropody by a registered medical practitioner.

HOUSE OF COMMONS.

THURSDAY, MAY 10TH.

Government Subsidy and Housing Construction.

Dr. SALTER asked the Minister of Health whether he was aware that, following the reduction in the subsidy, there had been a marked falling off in the number of houses under construction or authorised under the 1923 and 1924 Acts; and whether, with a view to stimulating local authorities to undertake wide schemes of building for letting, he would give an early assurance that the present rates of Exchequer assistance would be available for all houses completed by Sept. 30th, 1929.—Mr. CHAMBERLAIN replied: I am aware that as compared with the abnormally high rate of house construction just before the reduction of the subsidy became operative, the subsequent statistics showed a falling-off in the rate of house-building. The latest figures indicate that the rate is now increasing again. With regard to the last part of the question, although I cannot, of course, anticipate what the result will be of the statutory review of the subsidy at present payable, which must be undertaken after Oct. 1st next, I have in the meantime decided that houses completed by March 31st, 1929, shall, if otherwise elegible, qualify for subsidy at the existing rates.

London Schools for Mentally Defective Children.

Mr. ROBERT MORRISON asked the President of the Board of Education (1) the number of London special schools for mentally defective children closed during the past five years, and (2) the number of mentally defective children at present on the roll of London special schools, and the corresponding number for 1918.—Lord E. PERCY replied: Since April 1st, 1923, 18 London special schools for mentally defective children, providing 1332 places, have been closed. The number of children on the rolls of special schools for mentally defective children has fallen from 6994 on March 31st,

1924, to 5594 on March 31st, 1928. The corresponding figure on March 31st, 1918, was 7004. I may add that the standard of ascertainment of mentally defective children in public elementary schools in London has remained practically constant for several years, and the number of children so ascertained has fallen from 12·64 per 1000 in 1923 to 11·22 per 1000 in 1927.

Publication of New Medical Discoveries.

Sir BASIL PETO asked the Minister of Health whether the General Medical Council or the Medical Research Council were concerned with the investigation of new discoveries in connexion with, and new treatments of, disease; if not, whether there was any body of medical men in this country whose business it was to make such investigation officially; and, if not, how his department was kept advised of such new discoveries and treatments.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the negative as regards the General Medical Council, and in the affirmative as regards the Medical Research Council. The recognised method of bringing a new discovery to notice is publication of the scientific evidence for it in a technical journal. This allows its value to science or practice to be confirmed or otherwise by other workers.

Sir BASIL PETO: As the public generally do not read the technical medical papers, can the right hon. gentleman say in what way the public can be informed in view of the action which is taken by the General Medical Council in the case of any member of the profession who advises the public of a new treatment by any communication in the public press?

Viscountess ASTOR: Is it not the view of the right hon. gentleman that the less the public know, read, and think about disease the freer they will be from it?

Mr. CHAMBERLAIN: I cannot admit that it is not desirable that alleged new medical discoveries should be submitted to technical examination, and I do not think that it is possible for the Medical Research Council to take any useful action unless they have the benefit of some such publication as I have suggested.

A County Medical Officer's Appointment.

Mr. WILLIAM M. ADAMSON asked the Minister of Health what conditions had been laid down by his department in connexion with the appointment of the county medical officer for Salop; and, seeing that the Salop County Council now disputed the terms proposed, what action he proposed to take to bring about a settlement.—Mr. CHAMBERLAIN replied: No special conditions have been laid down by my department in connexion with this appointment, but I have suggested to the County Council that in making the appointment they should have regard to the standard salaries for such appointments which have been commended by my department for the guidance of local authorities. As regards the last part of the question, I am informed that the County Council have deferred consideration of the matter for the present.

MONDAY, MAY 14TH.

Administration of the Sale of Food and Drugs Acts.

Dr. VERNON DAVIES asked the Minister of Health if the Sale of Food and Drugs Act was administered by the health authorities in any county, and, if so, in how many.—Sir KINGSLEY WOOD replied: Yes, Sir. In some counties the public health committee or the medical officer of health, or both, take part in the administration of the Sale of Food and Drugs Acts. I regret that I cannot state the number of such counties.

Leprosy in Palestine.

Sir ROBERT THOMAS asked the Secretary of State for the Colonies the number of lepers in Palestine; whether they were segregated in hospitals or homes; and what other provision existed for their care and treatment.—Mr. AMERY replied: In February, 1926, it was estimated that there were less than 80 lepers in Palestine. I am not in possession of more recent figures, but the High Commissioner then informed me that the disease appeared to be dying out naturally. In 1927, the Moravian Leper Hospital at Jerusalem had on the average 29 in-patients, and 24 lepers received out-patient treatment at Government dispensaries. The High Commissioner is satisfied that sufficient facilities exist in Palestine for the treatment of leprosy.

QUEEN MARY'S HOSPITAL FOR THE EAST END.—Last week the Queen opened the Dr. Nicoll Memorial Wing of this hospital at Stratford. The additions, which comprise a solarium for sunlight treatment, large children's ward, two additional wards for men and women, an enlarged X ray department, and new administrative quarters, are in memory of the late Dr. P. Nicoll who worked earnestly and devotedly in the interests of the institution for 30 years. The Queen unveiled a tablet over a bed endowed to his memory.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A an ordinary meeting of the Council on May 10th Sir Berkele Moynihan, the President, in the chair, diplomas of Membe were conferred upon 152 candidates. Their names ar included in the list of licentiates of the Royal College Physicians, which appeared in our issue of May 5th, with th exception of A. W. D. Cooke, S. McGladdery, H. H. Mahmoo J. W. Notley, and J. M. Oldaker, who have already receive the diploma of M.R.C.S., and Ralph Henry Morley, Leec University, whose Membership was conferred at this meetin but who will not receive his licence until a later date.

The undermentioned diploma was conferred (joint with the Royal College of Physicians) upon the followir candidates:—

DIPLOMA IN PUBLIC HEALTH.

J. S. Anand, H. S. Bawa, J. D. Bilimoria, J. C. Blake, M. Bur L. Fay, M. M. Khan, J. M. Mackay, Elsie J. Mann, W. Masters, C. M. Nicol, G. H. Pringle, Winifred E. Probe W. E. Snell, N. H. Tadiwala, F. F. Udvadia, Madeline H. Umpleby, and Margaret Ward.

UNIVERSITY OF LONDON.—The report of Mr. Franklin Sibly, D.Sc., the principal officer, on the work the University during the year 1927–28, has been issue The total admissions by all channels during 1927– amounted to 9119, as compared with 7668 in 1926. T total number of candidates for all examinations was 33,9(as against 33,220 last year. It is interesting to note th matriculation and registration candidates numbered nea 600 more than last year, while candidates for first a higher degrees were fewer. Benefactions specially affecti the medical faculty include generous contributions from t Rockefeller Foundation, while Messrs. A. Wander, Lt the Imperial Chemical Industries, Ltd., and Messrs. Lyons and Co., Ltd., have helped towards the endowme of a Chair of Dietetics, to be attached for the present St. Thomas's Hospital Medical School. The Trust De establishing the Geoffrey E. Duveen Lectureship in Otolo is being varied to allow of the establishment of a Travelli Post-graduate Studentship in Oto-Rhino-Laryngology a of a fund for the promotion of research in that subje The principal officer records changes in personnel of teach and the institution of various new chairs and readershi He mentions that the Holiday Course for Foreigners, t twentieth of the series, held at King's College for Wom Household and Social Science Department achieved great success. The number of applications showed marked increase on the previous year, over 550 havi to be refused. He concludes by an allusion to the f that the University has now the land on which to build house and that its duty and privilege will be to order th house so that it becomes to future generations their ho

Middlesex Hospital (University of London).—A cou of three lectures on Graves's Disease, with lantern illust tions, will be given at the Middlesex Hospital Medi School, Cleveland-street, W., at 5.30 P.M., on Tuesd Wednesday, and Thursday, May 29th, 30th, and 31st, Dr. John Eason, physician to the Edinburgh Ro Infirmary.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOAR *Medical Scholarships.*—Six medical scholarships and ex bitions, of an aggregate total value of £513, tenable University College Hospital Medical School, the Lon (Royal Free Hospital) School of Medicine for Women, the London Hospital Medical College, will be offered competition at the examination commencing on June 2 Full particulars and entry forms may be obtained from Secretary of the Board, Mr. S. C. Ranner, M.A., The Med School, King's College Hospital, Denmark Hill, Lond S.E. 5.

LEBANON HOSPITAL FOR MENTAL DISEASES.—T twenty-ninth annual meeting of this hospital in Syria take place at Friends House, Euston-road (opposite Eus Station), on Tuesday, May 22nd, at 3 P.M., Sir Wyndh Deedes, late Chief Secretary to the Palestine Governm in the chair. An address will be given by Sir Maurice C on the Treatment of Early Mental Disorder, and the ot speakers will include Sir Robert Armstrong-Jones Dr. Bedford Pierce. The Lebanon Hospital is the place for the treatment of mental disorders in Syria, an also a teaching centre for psychiatry in the Near East. I administered on an international and undenominati basis, under a British medical director. All who are intere are invited to attend this meeting, and further particulars obtainable from the London office, 139, Marylebone-road.

UNIVERSITY OF NOTTINGHAM.—The buildings of this new university will be opened by the King and Queen on July 10th.

THE Minister of Health has appointed Mr. A. B. Maclachlan to be a Principal Assistant Secretary and Mr. M. Heseltine, C.B., to be an Assistant Secretary of the Ministry.

THE X ray department in the new extension of the Mildmay Mission Hospital, Austin-street, Bethnal Green, will be opened by Sir Percy Shepherd to-day, Saturday, May 19th, at 3 P.M.

MINERS' ACCIDENT RATE.—The annual report of the Lancashire and Cheshire Miners' Permanent Relief Society shows that approximately one in every six of the 56,354 members was injured last year.

Dr. George H. F. Nuttall, F.R.S., Quick Professor of Biology in the University of Cambridge, has recently been elected Foreign Corresponding Member of the Academy of Medicine, Paris.

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND.—At a recent meeting of the Council of the Union, Messrs. Millar, Thomson, and Dunlop, C.A. (113, St. Vincent-street, Glasgow, C. 2), were appointed secretaries and treasurers, and Messrs. Brown, Mair, Gemmill, and Hislop (162, St. Vincent-street, Glasgow, C. 2) law agents to the Union.

SUNSHINE IN MANCHESTER.—It is reported that the average number of hours of sunshine in Manchester during the last six years was less than 900, whereas at Southport, in the same latitude, the figure was between 1400 and 1500. At Southport this figure has remained approximately constant for 20 years, but Manchester's sunshine has diminished in the same period from 1149 to 859 hours per annum.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION. Arrangements have been made for post-graduate teaching in Glasgow from June to October, under the auspices of the above association. There will be a general medical and surgical course, special clinical courses, and clinical assistantships will be available. Copies of the syllabus for the summer session may be had from the secretary of the association, at the University, Glasgow.

A COMMITTEE appointed by the Royal Medico-Psychological Association is engaged in compiling a memorial volume to the late Sir Frederick Mott. It is hoped that it may be ready in the early autumn. The title suggested is "Contributions to Psychiatry, Neurology, and Sociology. Dedicated to Sir Frederick Mott by His Colleagues, Friends, and Former Pupils." The publication has been entrusted to Messrs. H. K. Lewis and Co., Ltd.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.—This association has arranged a series of lectures demonstrations at St. James's Hospital, Ouseley-road, Balham, S.W. The name of the lecturer and the subject will be given each week in our Medical Diary. On Tuesday, June 12th, a visit will be paid to King Edward's Sanatorium, Midhurst, and on Wednesday, June 27th, a demonstration will be given at the Cassel Hospital for Functional Nervous Disorders, Penshurst. The Secretary is Dr. R. J. Saunders, 9, Lyford-road, Wandsworth Common, S.W. 18.

NATIONAL UNION OF SOCIETIES FOR EQUAL CITIZENSHIP.—A conference on Women in the Service of Hospitals was convened in London by the Union on May 8th and was attended by representatives of a large number of organisations. The need for adequate facilities for the training of women medical students was discussed by Dr. Graham Little, M.P., who moved a resolution protesting against the exclusion of women medical students from all the London general hospitals having training schools—with the exception of the Royal Free Hospital and a limited number of students at the University College Hospital—and calling upon the Union to organise a representative committee which could make representations on this subject to the hospitals and public bodies concerned. Miss Eleanor Rathbone, President of the Union, pointed out that the hospitals are supported by subscriptions from women as well as men. The particular need for qualified medical women in mental hospitals was argued by Dr. Isabel Wilson, and Dr. Margaret Emslie, in moving a resolution calling upon those responsible for the administration of hospitals to ensure the appointment of women both on the committees of management and to medical staff posts, referred to the special qualifications which trained medical women can bring to maternity and child welfare work.

UNIVERSITY OF GLASGOW.—On June 20th the honorary degree of Doctor of Laws will be conferred on Prof. G. W. Crile, of Cleveland, Ohio, and on Madame Curie, of Paris.

Dr. K. St. Vincent Welch, of Sydney, has been appointed as first doctor under the Australian Inland Mission's Aerial Medical Service.

ROYAL SOCIETY OF MEDICINE.—The Society's house and library will be closed on Saturday, May 26th, and Monday, May 28th.

BOLINGBROKE HOSPITAL, WANDSWORTH.—According to the annual report the average cost of an in-patient has fallen from £7 13*s.* 3*d.* to £7 6*s.* 5*d.*

EAST SUSSEX COUNTY COUNCIL.—Dr. A. G. R. Foulerton, who is shortly retiring from the position of county medical officer of health for East Sussex, was on May 8th appointed hon. consulting medical officer to the county council.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—Examinations for the certificate in psychological medicine and for the Gaskell prize will be held at the Maudsley Hospital, Denmark Hill, London, S.E., on May 31st and June 1st. Particulars will be found in our advertisement columns.

A GIFT TO NEWCASTLE-UPON-TYNE INFIRMARY.—Sir Walter Runciman has promised to give £50,000 towards the cost of enlarging this hospital, which has a waiting-list of 2000. The extensions will cost £150,000. The buildings have been twice enlarged since 1906 and there are at present 534 beds, but these are still inadequate to the demands of a huge population.

ROYAL BERKSHIRE HOSPITAL.—Mr. J. H. Benyon, Lord Lieutenant of Berkshire, recently opened at this Reading institution new operating theatres, made necessary by the great increase in the number of operations; these have nearly quadrupled in the last 20 years. There are two theatres in a detached block connected with the main building by a covered way. Instead of the familiar plate-glass north windows they are lighted by large roof lights.

DONATIONS AND BEQUESTS.—Major Walter E. Elliot, M.P., Under Secretary of State for Scotland, on May 8th, on laying the foundation-stone of the reconstructed and enlarged Northern Infirmary at Inverness, the cost of which will be over £100,000, announced the gift to the infirmary of the sporting estate of Kintail, valued at £50,000, the benefaction of Mr. Alexander Edward, of Forres. The reconstruction is to cost £100,000, of which £74,000 has already been voluntarily subscribed.—At the recent meeting of the Glasgow University Court it was intimated that Mr. William C. Teacher, of Cove, Dumbartonshire, had made a gift of £10,000 for the foundation of a lectureship in bacteriology at Glasgow Royal Infirmary.—Sir Edward Holt, Bart., of Manchester, among other bequests, left £5000 to the Manchester Northern Hospital in memory of his son, Captain Joseph Holt, who was killed in Gallipoli, £1000 each to the Manchester Royal Infirmary, the Salford Royal Hospital, St. Mary's Hospital and Dispensary for Women and Children, Harpurley District Nursing Association, £5000 to the Manchester Radium Institute, and £1000 to the Humphrey Chetham Hospital and Library in Manchester.

ROYAL WEST SUSSEX HOSPITAL.—At the recent annual meeting the governors submitted a recommendation that out-patient letters be discontinued, and the statute amended accordingly. In support of this it was stated that these letters had been abolished at hospitals all over the country, and in some places in-patient letters as well. Against the proposal it was argued that some people would take a far greater interest in the hospital because of the letters. The governors decided that out-patients' letters be only issued on application to the secretary. It was stated that the contributory scheme was increasing in membership at the rate of about 400 a month, and that the actual membership at the moment was 12,400, covering about 25,000 people. It was hoped that the ultimate total would be 20,000 actual members, which would produce at least £6000 a year, 90 per cent. of which would go to the hospital. The year's finances (to March 31st) showed, despite the exercise of every economy, a deficit of nearly £2000, which the governors liquidated by a decision to sell out investments or transfer from the trustees' accounts. The sum of £12,800 has so far been subscribed to the centenary fund.

ENLARGEMENT OF SWINDON HOSPITAL.—It is proposed to enlarge the Swindon and North Wilts Victoria Hospital at a cost of £33,000. A contributory scheme to help the maintenance fund is about to be launched.

VICTORIA PARK HOSPITAL.—The new block of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., will be opened shortly by the Duke of Connaught, the President. It will provide especially for surgical and radiological needs. The governors are anxious to reopen the sanatorium at Saunderton, Bucks, which has been closed for two years for lack of means to maintain it.

YORK COUNTY HOSPITAL.—An extension of the eye, ear, nose and throat departments of this institution has just been opened. The beds in the eye department are increased from 16 to 24, and Dr. Peter Macdonald, the principal ophthalmic surgeon, stated that this would be the first hospital in England to be equipped with the new electrophonoidal apparatus for the treatment of chronic deafness. The hospital contains 180 beds, but Dr. Macdonald said that it serves so large a population that it requires double that number.

PLAY-READING IN AID OF A WELFARE CENTRE.—An interesting character-study of a divided personality was presented in the play "I. E. Robinson," a reading of which was given by Mr. Peter Davey, at Mitford House on May 14th in aid of a welfare centre. The initials "I. E." stand for "Impostor-Explorer," and the author, Miss B. L. Bowhay, deals sympathetically with the motives of an American chemist with a persistent exploration-phantasy, which he gratifies at the expense of truth. The play showed an intimate knowledge of life in the Southern Mississippi States and of scientific possibilities.

TRAFFIC ACCIDENTS AND HOSPITALS.—The annual report of Leicester Royal Infirmary states that last year 1169 persons injured in traffic accidents were treated, of whom 221 were admitted to the wards. With 72 exceptions these accidents were caused by motors and bicycles.—On Sunday, May 6th, accidents on the Southend arterial road were so numerous that the Victoria Hospital at Southend was unable to cope with the casualties. Many accidents were dealt with at the two dressing stations of the St. John Ambulance Association; firemen were pressed into ambulance service; and at the most congested spot five policemen, instead of one, were on point duty.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, May 21st.—8 P.M., ODONTOLOGY (at the Royal College of Surgeons, Lincoln's Inn Fields). Election of Officers and Council. Paper: Sir Frank Colyer: The Pathology of the Teeth of Elephants.

TUESDAY.—5 P.M., MEDICINE. Election of Officers and Council.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Election of Officers and Council. Paper: Dr. J. P. McGowan: Aplastic Anæmia. A discussion will follow in which Dr. H. P. Bayon and Dr. A. Piney will take part.

THURSDAY.—8.30 P.M., UROLOGY. Election of Officers and Council. Paper: Mr. Clifford Morson: Observations on the Radium Treatment of Vesical Carcinoma.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, May 21st.—9 P.M., Sir Archibald Garrod: Lessons on Rare Maladies. (Annual Oration.)

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, May 23rd.—5.30 P.M. (at St. John's Hospital, 49, Leicester-square, W.C.), Sir John Bland-Sutton: The Debt of Dermatology to Optical Glass. (Annual Oration.) The annual dinner will be held on the same evening at the Café Royal, 7 P.M.

NORTH-WESTERN TUBERCULOSIS SOCIETY.

THURSDAY, May 24th.—3 P.M. (at the Tuberculosis Offices, Joddrell-street, Hardman-street, Manchester), Dr. Jane Walker: Tuberculosis and Employment.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 21st, to SATURDAY, May 26th.—WEST END HOSPITAL FOR NERVOUS DISEASES, Gloucester Gate, Regent's Park, N.W. Clinical demonstration of the Fundus Oculi (ophthalmoscopes required) by Mr. Lindsay Rea, at the In-patient Dept., Gloucester Gate, on Fri., at 8.30 P.M.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Clinical demonstration (gynæcological) by Mr. A. C. McAllister, on Fri., at 10 A.M. The above demonstrations are free.—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C. Intensive course—clinical and operative. Third week. Occupying all day.—NATIONAL HOSPITAL, Queen-square, W.C. Course in Neurology for two months.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Course in Psychological Medicine. Last week. Further information from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, May 21st.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Monday and Wednesday, at 2.30 P.M., there will also be demonstrations of Gynæcological and Skin Cases by Mr. Aubrey Goodwin and Dr. W. Jenkins Oliver.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

MONDAY, May 21st.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M. Dr. Trevor Davies: Gynæcological Department.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Department.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Children's Medical Out-patients.

TUESDAY and FRIDAY, May 22nd and 25th.—4.30 P.M. Special Lectures, Dr. Page: Anæsthetics.

Daily, 10 A.M. to 5 P.M., SATURDAYS, 10 A.M. to 1 P.M. In-patients, Out-patients, and Special Department Anæsthetic and Operative Surgery Courses.

UNIVERSITY COLLEGE, Gower-street, London, W.C.

MONDAY, May 21st.—5.30 P.M., Prof. R. G. Harrison (Yale): Modern Trends in the Study of Animal Development.

TUESDAY, May 22nd, THURSDAY, May 24th, and FRIDAY, May 25th.—Prof. L. H. Henderson (Harvard): Blood: a Study in General Physiology.

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, May 23rd.—3.30 P.M., Dr. T. J. Hoskin: Rheumatic Heart Disease; Its Incidence and Prevention.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

WEDNESDAY, May 23rd.—4 P.M., Mr. Charles Heath: Middle-ear Disease.

ROYAL NORTHERN HOSPITAL INTENSIVE COURSE, Holloway-road, N.

MONDAY, May 21st.—2.15 P.M., Mr. L. E. Barrington-Ward: Demonstration of Surgical Cases. 3.15 P.M., Dr. Bruce Williamson: The Pneumonias in Children.

TUESDAY.—2.15 P.M., Mr. N. A. Jory: Treatment of Chronic Suppuration of Middle Ear. 3.15 P.M., Mr. J. Hunter: The Surgical Aspect of Goitre.

WEDNESDAY.—2.15 P.M., Mr. T. T. Higgins: Further Experience in the Treatment of Varicose Veins by Injection. 3.15 P.M., Dr. A. Lisle Punch: Fibrosis of the Lung.

THURSDAY.—2.15 P.M., Dr. W. H. McKinistry: Pathological Specimens. 3.15 P.M., Dr. P. O. Ellison: Pathological Investigations.

FRIDAY.—2.15 P.M., Dr. M. Donaldson: Displacement of the Uterus. 3.15 P.M., Dr. C. Gouldesbrough: Diagnosis of Gall-bladder Lesions by X Ray.

T. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.
THURSDAY, May 24th.—5 P.M., Prof. R. H. A. Plimmer: Some Recent Researches on Vitamins.

ATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, May 21st.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Riddoch: Spastic Paraplegia (2).

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Tumours of the Spinal Cord.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Walshe: Neurosyphilis (1).

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educative Exercises (in Exercise Room).

ANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, May 22nd.—4.15 P.M., Dr. E. B. Leech: Some World Experiences with Gastric and Duodenal Ulcer.

NIVERSITY OF BIRMINGHAM POST-GRADUATE LECTURES.
THURSDAY, May 24th.—4 P.M. in the Medical Lecture Theatre, Edmund-street Buildings), Dr. Malcolm Campbell: The Value of Mineral Baths in Certain Conditions of Joints and Muscles.

NIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, May 25th.—3.30 P.M. (at the Royal Hospital), Dr. Imrie: Laboratory Aids in Diagnosis and Treatment of Gastro-intestinal Disease.

Appointments.

LIVINGSTON.—On May 9th, at Welbeck-street, the wife of Squadron-Leader P. C. Livingston, F.R.C.S.E., R.A.F., of a son.

MARRIAGES.

BENZECRY—GABRIEL.—On May 8th, at Spanish and Portuguese Synagogue, Lauderdale-road, W., Dr. J. S. Benzecry to Lillian, daughter of Mr. and Mrs. W. M. Gabriel, of Pembridge-villas, W.

DOYLE—HUTTON.—On May 10th, at St. Alban's Church, Teddington, Middlesex, Martin Redfern Doyle, M.R.C.S., L.R.C.P., to Nella, only daughter of the late Henry Hutton and Mrs. H. Hutton, of Teddington.

DEATHS.

CLARK-JONES.—On May 8th, 1928, at 1, St. Matthews-gardens, St. Leonards, Edwin Clark-Jones, M.R.C.S. Eng., L.R.C.P. Lond., aged 49 years.

GILMOUR.—On May 13th, suddenly, at his residence, Wimbledon Park, Andrew Gilmour, M.D., M.R.C.P. Edin., D.P.H., M.O.H., Wimbledon, in his 52nd year.

PRATT—On May 10th, at Fern Grove, Hainton-avenue, Grimsby, Lincs., Arthur Alfred Pratt, M.D., aged 60 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SUNLIGHT IN MODERN MEDICINE.

IN the course of a Chadwick Lecture delivered in London on May 15th, Major Walter Elliot, M.P., said that experience in England showed that the best results of treatment by ultra-violet rays were obtained in lupus, certain skin conditions, rickets, and superficial lesions in surgical tuberculosis. The general conclusions of the reports received by the Ministry of Health were that while ultra-violet light was by no means a general specific for all forms of disease, it formed a useful accessory therapeutic weapon. The Scottish verdict was somewhat more enthusiastic, and a special report by the Board of Health said that "its value in the less severe forms of non-pulmonary tuberculosis is unquestioned. In pulmonary cases the results have not been discouraging but much more work will require to be done. In child welfare work, on the whole, the results are most encouraging. They fully justify the expense and labour involved in providing this method of treatment." A clue to these differences of opinion might be found in the different amount of ultra-violet radiation recorded in the two countries. At Ventnor, Isle of Wight, the average daily readings for November and December, 1926, was 2·35. At Edinburgh the readings were nil for the whole three months between November, 1925, and March, 1926, and even in March and April the readings only averaged 1·1. A supplementary source of ultra-violet light might therefore be expected to show more obvious results in the north than in the south.

In conclusion, Major Elliot remarked that the fundamental requirements of the normal being—fresh air, fresh water, fresh food—were yet far from being met by the people of this country. Till they were fulfilled the administrator would have a part to play in the twentieth century not less important than he had in the nineteenth.

MEDICAL WOMEN'S FEDERATION.

THE annual dinner of the Medical Women's Federation, held in the Edward VII. Rooms, Hotel Victoria, London, on May 10th, and attended by more than 200 of its members, was a lively and successful occasion.

Dr. Christine Murrell, who was in the chair, made no formal speech, but succeeded in stimulating other speakers by her felicitous remarks in introducing them. The toast of "The Federation" was proposed by Sir Robert Bolam, who congratulated medical women on having seized the opportunity offered to them during the war of obtaining privileges which were rightly theirs, and on uniting to hold them for the common good. He expressed a hope that the time would come when a separate women's organisation within the British Medical Association would become unnecessary. Dr. Letitia Fairfield, who responded, believed that such a time would never come, for medical women had much to gain by standing together and acting as a unit. The Federation, which now had a membership of over 2000, included 14 local federations, and was itself a member of an international group comprising 14 countries. She solicited the aid of the Association in removing from medical women the cruel disability imposed upon them by local authorities when they committed matrimony. In general practice, she said, women were increasingly making good. Dr. Clara Stuart proposed "The Guests," who, she said, were representative of many ranks and professions. Response for the women guests was made by Mrs. E. D. Simon, sometime Lady Mayoress of Manchester, who spoke with eloquence on the wholesome effect of publicity on the position of women in public life. Women teachers in Manchester had recently achieved their right to matrimony without dismissal owing to the searching light thrown upon the controversy in the public press, and she did not doubt that proper ventilation would have a similar happy result in the problem of women's medical education which had been raised in London. Sir Walter Fletcher, who also responded, spoke of the work of women in various spheres of medical research, especially in the regions of cancer, radium, and food deficiency. He announced that pressure was now being brought upon authority to obtain a fuller supply of radium in this country. Prof. M. Lucas Keene eulogised "The Chairman" as an example of successful general practitioner and faithful pioneer of women's freedom. Apart from the guests already mentioned, there were present amongst others Lord and Lady Balfour of Burleigh, Sir Herbert Waterhouse, Major-General J. B. Smith, Mrs. Philip Snowden, Sir Gregory Foster, eminent headmistresses in the persons of Miss Lowe, M.A., Miss Tuke, M.A., and Miss Sparks, M.A., Dame Janet Campbell, Dr. Jane Walker, Dr. Catherine Chisholm, Prof. Winifred Cullis, Dr. Graham Little, M.P., Dr. James Neal, Prof. Grey Turner, and Miss Musson, R.R.C.

VACCINATION IN THE IRISH FREE STATE.

OUR Dublin correspondent writes: The division on th second reading of Mr. Everett's Vaccination Bill, a privat measure intended to introduce a "conscientious objection clause to the Irish vaccination laws, was taken last wee in the Dail, and resulted in the defeat of the Bill by 75 vot to 39. There were members of every party in both divisio lobbies, though ten members of the Government and nearl all their supporters voted against the Bill. All the medic men in the Dail, with one exception, opposed the Bil The exception was Dr. Ryan, one of the deputies for Count Wexford, the antivaccinationist stronghold. For the pa few weeks all deputies have been nearly "snowed under by the showers of propagandist literature which reache them from London. It is satisfactory that, in spite of th active agitation in favour of the Bill, nearly a two-thir majority of the Dail showed determination to maintain th full rigour of the existing vaccination laws. Both th President of the Executive Council and the Minister f Local Government and Public Health (Mr. Mulcahy) mad strong speeches against the Bill. It may be hoped that th Department of Local Government and Public Health w be able now to insist on the existing laws being carried ou

THE CHILD'S LOG.

ALL sensible parents keep some record of their children growth in length and weight, if not in grace. It was, v believe, the late Mr. Jonathan Hutchinson who first design a more elaborate record which might not only be of intere to the diarists but have some anthropological value. A elaborate log-book has now been designed by Eva Viscounte Erleigh with the attraction of copious illustrations Ernest H. Shepard. In a prefatory note Dr. Eric Pritcha vouches for the accuracy of the information given and f the soundness of the principles of mothercraft inculcate "The Little One's Log" is published by Partridge, Londo at 7*s.* 6*d.*

CHRONIC OSTEOMYELITIS IN LONG BONES.

Lieut.-Colonel H. Hallilay, I.M.S. (Rawalpindi), write In connexion with my article under this title in your iss of March 10th (p. 490), I have received a letter from M Seton Pringle (Dublin) in which he says: "You seem have worked out an operation almost identical to one whi I described years ago in the *British Journal of Surger* I enclose you a reprint of this article. I have not found a reason to change my opinion or alter the technique to a extent as my experience increased." I had not read M Pringle's article, and I honestly thought I had devis something new. There is, however, nothing new under t sun, an adage of which I am reminded by this incide since Mr. Pringle's article and the operation which describes is indeed almost identical with my own.

HYGIENE AND SANITATION IN BRITISH MALAY

THE Handbook of British Malaya for 1927, compiled Mr. R. L. German, of the Malayan Civil Service, a published with official authority, is an admirable illustrat guide to the public life of the Malayan States, and to vegetable and mineral resources. Chapter XI. sets out t organisation for the promotion of hygiene, giving t prevalence of zymotic and other disease in the varic districts, classified according to the very varied rac inhabitants. The handbook, which is well indexed a contains a useful map in the back cover, may be obtain at the Malay States Information Agency, Malaya Hou 57, Charing Cross, London, S.W., for 2*s.* 6*d.*

Queen's University, Ontario, has received an offer £10,000 from a resident in Chicago to found a chair preventive medicine and public health.

Dr. Pietro Bini, of the Hospitals of S. Chiara at Pi tells us that on April 28th the *Popolo d'Italia* published note by him on the rescue of personnel from a sunk su marine. It appears that Dr. Bini has constructed a worki model of an apparatus which, as soon as the submarine h been reached and the compartment containing the surviv located, enables a single diver in the space of a few minu to put the rescue ship in a condition to provide for th pure air, electric light, telephone, food, and other necessit to preserve life. Meanwhile the inventor is awaiting invitation to demonstrate his apparatus before a judic committee of the National Institution of Research.

A preliminary report by the County Tuberculo Committee in the area of the Lancashire County Cour shows that the number of deaths from pulmonary tub culosis in 1927 was 1401, a decrease in comparison wi previous years, and the death-rate from this form of disease—viz., 0·61 per 1000 of the population—is again lowest on record. For non-pulmonary tuberculosis death-rate of 0·16 per 1000 is the same as in 1926, and only half what it was in 1914.

The Lessons OF RARE MALADIES.

The Annual Oration delivered before the Medical Society of London on May 21st, 1928,

BY SIR ARCHIBALD GARROD, D.M., K.C.M.G., LL.D., F.R.S.

TO-DAY, when the echoes of his tercentenary have scarcely died away, and the work of William Harvey is in all our minds, it is fitting that I should take, as the text of my discourse, some words of his which appear to me to state my thesis better than had ever been done before, or has been done by any more recent writer. The passage to which I refer is contained in a letter which Harvey wrote, only six weeks before his death, to a Dutch physician, Dr. Vlackveld of Haarlem, who had asked his opinion upon an unusual specimen. Translated, it runs as follows :—

" It is even so—Nature is nowhere accustomed more openly to display her secret mysteries than in cases where she shows traces of her workings apart from the beaten path ; nor is there any better way to advance the proper practice of medicine than to give our minds to the discovery of the usual law of Nature by careful investigation of cases of rarer forms of disease. For it has been found, in almost all things, that what they contain of useful or applicable is hardly perceived unless we are deprived of them, or they become deranged in some way."

There are many of us to whom a scientific research appeals in proportion to its practical utility, and others for whom a discovery loses much of its charm when applied to practical uses. So, too, I take it, there have always been, and always will be, many members of our profession to whom the study of those common diseases which are of so great practical importance, and to cope with which is the daily task of the medical man, make the strongest appeal, whereas for others, who form but a small minority, the investigation of rare maladies has a special attraction.

Undoubtedly the collector's instinct is very widespread, and in early life is almost universal. To form a good collection of stamps, birds' eggs, or butterflies is the ambition of most boys ; and such ambitions persist into later life, although the field of the collector may change. With this instinct is mixed up what may be styled a " superiority complex," a desire to outvie one's fellows, to break some record, to climb some untrodden peak, or to acquire some outstanding work of art. To attain to such ends men will brave injury, disease, or death. No doubt this instinct has a share in the lure of rare maladies, but if that were all, and if the pursuit of such studies had no other aims, I should not be speaking of it this evening. It is rather, as Harvey saw so clearly, because we find in rare diseases the keys to not a few dark places of physiology and pathology, that I would recommend them to you as objects of study.

Even Morgagni, who held that there was no other road to medical knowledge than the collection and comparison of many cases of disease and of dissections, added that he did not despise, but specially studied, those which are rare and remarkable, despite the fact that their rarity makes such collation difficult.

We are told that in France, at the time of the first empire, when the French universities were in the melting-pot, there were established, in some of the medical schools, professorships for the exposition of rare cases and diseases ; and in the " Dictionnaire des Sciences Médicales," published in 1813, there is an article by Fournier on rare cases which extends to no less than 120 pages. In our own medical journals and transactions I have found only two addresses on the subject, but the authors of these were both giants in their generation, in whose footsteps one treads with timidity. In 1882 Sir James Paget [2] opened the series of Bradshaw Lectures at the Royal College of Surgeons of England with a discourse on Some New and Rare Diseases, and in 1889 Sir Jonathan Hutchinson [3] stood in this place, and delivered the annual oration on the Clinical Uses of Rare Diseases.

Fournier's article, like the compilations published in earlier centuries by Zacutus Lusitanus and others, refers to a large number of cases, gathered from different sources. Some of them are fantastic ; spontaneous combustions, scorpions in the brain, and the like ; some are of great interest, such as a pineal tumour, a large salivary calculus, and a family with hæmophilia ; and yet others are most intriguing, such as one quoted from Vepfer, which I have, as yet, failed to trace, of an elderly hemiplegic with yellowness of the skin limited to his paralysed side, and even to one half of his nose.

But the cases are thrown together higgledy-piggledy, with no systematic arrangement, and no suggestive comments. Just so in some museums collections of great value lose much of their educational value for lack of proper grouping ; whereas in others, by skilful arrangement of material, perhaps less precious, we are shown the stages of evolution of living things, or of man's tools, weapons, or playthings. It is in the latter spirit that Paget and Hutchinson approached their subject, and I cannot forbear to quote a passage from each address, so characteristic in its phrasing that the elder among us will seem to hear the voice of the author behind his words.

Thus Hutchinson :

" Amongst the infinitely varied derangements of structure and function which make up the total of human maladies we have some which are constantly before us, and others so infrequent that a man may live through a long professional life and scarcely see a single example of them. All will admit that the first must be studied, as a matter of duty, by every conscientious practitioner, but respecting the latter there is a wide-spread and very natural feeling that it does not matter whether we understand them or not. It is against this form of apathy that I wish to protest to-night, and I am not without hope of making it clear that these varieties are often the most instructive ; that they stand in close relationship to the common, and that it is the duty of all, so far as possible, to understand them, and to try also to further the knowledge of them."

Paget, speaking of rare cases, made the same appeal :

" But even as they are, singly and in disorder, we ought not to set them aside with idle thoughts or idle words about ' curiosities ' or ' chances.' Not one of them is without meaning ; not one that might not become the beginning of excellent knowledge, if only we could answer the question—Why is this rare ? or, being rare, why did it in this instance occur ? "

Harvey, Paget, and Hutchinson all suggest that the rarer maladies are specially instructive, but Harvey's reasons for the paying of special attention to such rarities appear to me the most convincing ; and even to-day, when the boundaries of knowledge have been so greatly widened, they could hardly be improved upon.

That the study of what may be styled Nature's experiments is of special value, and that many lessons which rare maladies can teach could hardly be learnt in other ways, it will be my aim to show. Nor is this true of diseases alone—as witness the part played by the strange birds and beasts of remote oceanic islands in the genesis of the theory of natural selection.

The material available is so scanty that, as Morgagni pointed out, the collection and comparison of many examples is out of the question ; but, in connexion with common and rare diseases alike, the careful study of individual cases may teach us much. As witness the work of James Mackenzie and of Thomas Lewis on the so common derangements of the heart's beat, and of Lewis and his fellow-workers upon the flush, the flare, and the wheal which result from a trifling trauma, such as a stroke, applied to the skin. These researches show us how immensely our knowledge might be enlarged if all such everyday phenomena were made the subject of accurate scientific investigation along similar lines.

There are two preliminary questions to be considered at the outset of our inquiry—namely, whether we need to draw a dividing line between rare cases and rare diseases; and, secondly, what is meant when we speak of a rare disease?

I think that the answer to the first question is in the negative. Any example of a rare disease is a rare case; and a rare syndrome may be due to a lesion of a common kind in an uncommon situation. Nor is it easy to define the meaning of the term disease, which is habitually applied to a great variety of conditions belonging to widely different categories.

As regards the second question, I do not propose to include maladies which are common in hotter countries, but rare in or absent from our own; nor infective diseases of the lower animals rarely met with in man; nor maladies due to dietary defects, such as scurvy, beri-beri, and pellagra; or which have become rare under changed conditions of life, such as chlorosis.

The truly rare maladies, of which I propose to speak, are such as are seldom seen in men living on any part of the globe nor under any conditions of life. It is true that a rare case may be only an extreme example of a condition which, in minor degrees, is common or well-nigh universal. As Hutchinson pointed out all of us whose fingers ever "die" suffer from a slight degree of Raynaud's disease, the text-book description of which is based upon extreme examples; but the rare malady, in the most strict sense, results from a lesion limited to a very unusual situation, or from some constitutional peculiarity of the patient which determines its occurrence. As often as not the patient and not his disease is exceptional.

A further question is, what is the criterion of rarity. I take it that between those common illnesses which go far to fill the wards of our hospitals, and those so uncommon that the recorded examples can be counted upon the fingers, every degree of rarity is represented. Yet there is not much practical difficulty in drawing the line, and it seems to me that the bulk of diseases fall into one or other of the more extreme categories, and that comparatively few are "*somewhat* rare."

You will remember that Harvey wrote: "that it has been found, in almost all things, that what they contain of useful or applicable is hardly perceived unless we are deprived of them, or they become deranged in some way." That is, indeed, one of the chief reasons why rare maladies can teach us so much. They call our attention to the ordinary things which we have accepted as matters of course without inquiry.

Thus a London street without a lamp-post is very rare, and it is possible that some of my hearers have walked down Sackville-street frequently, and yet have failed to notice that it is such a street, or that the lamps are carried upon brackets which project from some of the houses. When we do notice this, our thoughts turn to the history of street-lighting; back to days before those of the lamp-lighter of our boyhood, when the lighting depended upon the individual householders. So the unusual has called our attention to the usual and familiar, with the result that our knowledge is increased.

Again we accept without a thought our own asymmetry, and regard it as natural that our livers should lie to the right, our spleens to the left. When we meet with a case of transposition of viscera it sets us thinking, and we wonder what is the underlying cause of the more usual arrangement. The albino, too, with silvery hair and unshaded eyes, directs our thought to the problems of animal coloration.

To pass on from the general to the particular. One important and most instructive group of rare maladies includes those which are due to a strictly localised lesion of some particular organ, and in which the disease performs a physiological or pathological experiment. Tumours of the pituitary gland produce in some cases the syndrome which goes by the name of Fröhlich who first described it, and which is ascribed to lack of the hormones of that gland. Similar changes have followed destruction of the pituitary by a bullet; but no accidental nor surgical proceeding can, as some tumours appear to do, bring about over-activity of an endocrine gland. Despite the liability of certain organs to special kinds of tumours, it is to be expected that lesions so accurately localised will be, to say the least, uncommon; and this more especially when the lesion is not a tumour of a gland but an area of damage, due to hæmorrhage or inflammation, in some part of the central nervous system.

A larger number of rare maladies have, as their underlying causes, more or less abrupt departures from type such as are usually spoken of as mutations. These mutations, which are transmitted to offspring, either as dominant or recessive characters, may be in themselves disadvantageous to their subjects; or may entail such impairment of resistance to external influences that disease may result from apparently trifling causes, such as traumata too slight to induce disease in normal people: or that the agents of disease may find in them an unusually receptive soil. Given favourable conditions the same mutation may reappear from time to time, in subjects who do not inherit it, but hereditary transmission is far more common.

Such departures from type are often very instructive as throwing light upon problems of heredity, on the development of our bodies and of the living processes of which they are the seats, and on the liabilities of individuals to special forms of disease. Seeing that conspicuous mutations are not common, we have here an additional reason for the special interest which attaches to the study of rare maladies.

Unfavourable mutations—and it is with these alone that we are now concerned—are of various kinds. Some are anomalies of structure, and others of function. The structural mutations may manifest themselves as malformations, such as claw-hand or excess of digits; or as anomalies of tissues of a particular class such as the neuro-muscular systems, an affection of which, though obviously congenital and hereditary, develops only in late childhood, or even in adult life.

Functional mutations, like interferences with a delicate and complicated machine, bring about results which, however undesirable, may throw valuable light upon its normal working. So from the study of some rare maladies we gain much knowledge of diathesis, the constitutional factor in the causation of disease.

Idiosyncrasies also, those special sensitivities to certain protein substances, to pollens, foods, and drugs, have a share in the causation of some rare syndromes, which serve to throw light into dark places of physiology and pathology.

It will obviously be impossible, within the compass of a brief address, to do more than mention a very few examples amongst the many which might serve to illustrate my theme; and I will take as my first example one which is perhaps the most important of all, owing to the great value of the lessons which it has taught.

Addison's disease may be classed amongst the least rare of rare maladies, and all of us have met with cases of it. Although its signs and symptoms are conspicuous, our knowledge of it dates back only to the year 1855, to the publication of an epoch-making monograph in which were set forth the results of some researches of the great physician after whom it is named.

We can follow him, in the pages of his monograph, through the stage of clinical observation of a syndrome now familiar, each item of which, the pigmentation, asthenia, low blood pressure, and gastro-intestinal disturbances attracted his attention.

Simultaneously he recognised the pathological change associated with this fatal malady, the extensive disease, usually caseation, of the adrenal capsules. The association of the clinical and pathological pictures was so close that in his lat-

ases he was able to predict the adrenal lesions uring the lifetime of his patients.

Addison's pamphlet may serve as a model of cientific clinical medicine controlled by morbid natomy, and merely as such is of great interest. ut that is far from all, and in his preface its author escribes it as "a first and feeble step towards quiry into the functions and influence of the drenals, suggested by pathology"; for it was lear to him that it was the seat and not the nature f the lesions which determined the symptoms.

Before long it became clear that Addison's disease , in the great majority of cases, tuberculosis in an nusual situation. But even now there are still problems o be solved. We cannot yet explain each symptom s due to lack of some known product of the destroyed drenals. We do not know the cause of the gmentation, nor why the tuberculous lesions should often be limited to the pair of adrenal glands, which ppear to be seats of election of such infection.

From that "first feeble step" has grown up our nowledge not only of the functions of the adrenals, ut also of the other endocrine glands, and of the ormones which they secrete. As more has been arned about them we have come to recognise in iem the regulators of the metabolism of the tissues; nd not of metabolism only, but of height and weight, mperature, and blood pressure. It has become creasingly evident that the several ductless glands, cting, some as mutual opponents and others as llies, form a balanced mechanism, which sets limits these various functions, and by readjustments of hich the phenomena of puberty and of the climacteric e brought about.

It is true that long before 1855, exophthalmic oitre had been recognised and described by several bservers, Caleb Parry, Graves, Basedow, but it as not until much later that the signs of that sease were recognised as due to disturbance of the ternal secretion of the thyroid gland. Even as te as in 1889, Hutchinson, in his oration, referred Graves's disease and myxœdema as extreme forms common conditions, and added: "Not that they e in any way allied. The one is a functional nervous sorder, the other a slowly insidious change of ructure."

The most recent advances in endocrine studies; ie isolation and synthesis first of adrenalin itself, nd lately of thyroxin; the study of their physiological tions, and the utilisation of insulin, may rank nong the greatest achievements of medical science, nd all may be traced back, directly or indirectly, Addison's researches.

In like manner local lesions have helped to reveal ie functions of other ductless glands besides the drenals, but the lesions in question have been for the ost part tumours, some of which abolish the activities the affected structure, whereas we are led to lieve that an adenoma may actually enhance its ower of producing hormones. So in the case of the tuitary body tumours are capable of producing ch widely different pictures as acromegaly on the ie hand, and Fröhlich's syndrome on the other.

Save from information so afforded we know little the functions of the adrenal cortex, but an adenoma an adrenal has so frequently given rise to a aracteristic syndrome, that we cannot doubt that a sorder of the secretion of the cortex is its exciting use. So striking indeed is the appearance of a ild with such a tumour, an appearance which has en aptly likened to that of a brewer's drayman, e obesity, hirsuties, and florid countenance, that correct diagnosis has repeatedly been made before abdominal tumour could be felt. However, our nowledge of this matter is still far from complete, nd not at all comparable with what is known of ie functions of the thyroid and pituitary. What we know has been gained by the observation of cases a very rare condition.

No less rare are tumours of the pineal gland, which ave already yielded most suggestive information, though their message is still obscure. In a certain number of cases such tumours have been associated with a condition of premature puberty. Naturally such developments are only pronounced when the patient is below the ordinary age of puberty; but tumours of the pineal in adults, although giving rise to pressure signs, have failed so completely to induce changes suggestive of endocrine disturbance that it is inferred that the gland ceases to function before puberty. If so, it may be regarded as a "Peter Pan" gland, so to speak, the function of which is to restrain too rapid growing up. However, there are certain difficulties in connexion with such an interpretation, and there are some who maintain that the pineal is at no period an endocrine gland. We have as yet no clear experimental proof of its possession of such functions, and in some cases the syndrome has failed to develop, although all the needful conditions appeared to be fulfilled.

Evidence of a like kind, based upon the destruction of a special structure, has played an important part in the elucidation of the functions of the several parts of the central nervous system, for instance, Broca's observations upon the motor speech centre. Here again a tumour is more apt to produce a sharply localised lesion than is a hæmorrhage or an inflammatory process, and it is not remarkable that such lesions are uncommon.

To pass on now to a wholly different class of rare maladies I should have preferred, had it been possible to say nothing this evening about inborn errors of metabolism, a subject with which I fear to weary my colleagues; but to omit all reference to alcaptonuria would be to forgo some of the strongest arguments which can be brought forward in support of my thesis. Alcaptonuria is so rare an anomaly that, in all probability few of those present have ever met with it, although, when met with it is little likely to escape attention. It behaves as a characteristic Mendelian recessive character, and is wont to occur in several brothers and sisters whose parents are usually normal, but are in a large proportion of cases first cousins. Indeed, it was in this connexion that Bateson pointed out that consanguinity of parents is to be expected to be common in the case of a rare recessive character, to which both parents must contribute recessive gametes. Conversely, an anomaly which is so transmitted is presumably recessive, and so a valuable aid is provided to the recognition of recessive characteristics in man.

By the study of alcaptonuria from the standpoint of chemistry and by the administration to its subjects of a variety of aromatic compounds, much light has been thrown upon the catabolism of proteins, and especially upon the fate, within the organism, of the aromatic fractions tyrosin and phenyl-alanin, of which, almost alone among aromatic compounds, the benzine ring is broken up in the course of normal metabolism. Moreover, it has taught us how a metabolic product may have the power of staining certain living tissues in a selective manner; and lastly, we learn from this anomaly that a trifling deviation from the normal in metabolism, and the presence in the issues of small quantities of an intermediate product, normally destroyed, may so lower the resistance of tissues that after the lapse of many years there is developed, under the ordinary stress and strain of daily life, a characteristic form of osteo-arthritis. Here we are confronted with a tangible diathesis, a predisposition due to a recognised cause; and we may claim with confidence that, in this and in the several other ways mentioned, the study of alcaptonuria has contributed very materially to the advancement of medical science.

Still rarer than alcaptonuria is congenital porphyrinuria, or hæmatoporphyria, and although it stains the bones a deep brown colour, I have failed to find any records of human bones so stained, save in the few known cases of the anomaly. Such staining could hardly be overlooked at an autopsy, and the deep red colour of the urine is itself sufficiently conspicuous. It was the investigation of a case of

this kind which led Hans Fischer to embark upon fruitful researches upon the pigments of the porphyrin group, which have shown that these pigments appear much lower in the evolutionary tree than hæmoglobin, and even in so lowly an organism as yeast. Keilin's[4] discovery of cytochrome, which is so widely distributed a constituent of living cells, opens out new vistas, and adds greatly to the importance of such inquiries.

This anomaly has also taught us much regarding the action of light upon the living organism, and the origin of some skin affections which result from exposure to light.

My next example will be taken from that group of tissue anomalies which includes the familio-hereditary affections of the nervous and muscular systems, for which Gowers suggested the name of "abiotrophies," and which are fraught with valuable lessons for pathologists and clinicians alike. They illustrate various types of hereditary transmission, dominant and recessive and that peculiar form known as sex-linked recessive, which is transmitted by normal females to their male children.

They present morbid states which are obviously hereditary and inborn, but which give rise to no obvious signs or symptoms until some years after birth. If it be permissible to compare the human body to a bridge, so strongly constructed that it will last for many years, unless subjected to strains much greater than those to which it is habitually exposed, the body of the victim of an abiotrophy may be compared to a bridge so much less solidly built that it quickly suffers damage, and soon succumbs, under the strain of the ordinary daily traffic of the roads.

The abiotrophies, which, by the way, are not confined to neuro-muscular tissues, illustrate a point on which Hutchinson was wont to lay much—perhaps too much—stress, namely, the affinities between morbid states and their tendency to merge into each other. Thus in a particular family different tissue anomalies may crop up in different members, in one some form of muscular atrophy, in another a myotonia. In some instances this apparent affinity is due to an underlying anomaly of which the several symptom-complexes observed are all manifestations, just as local riots may be the only obvious signs of widespread popular unrest.

An excellent example of this is afforded by the malady known as dystrophia myotonica, and how our knowledge of it has developed is well told in a paper by Adie and Greenfield,[5] published in 1923. The story begins with the recognition of a group of cases in which a myotonia, such as is the conspicuous feature of Thomsen's disease, is associated with muscular atrophy of somewhat unusual distribution, facial, cervical, brachial, and sometimes peroneal—the Batten-Steinert-Curschmann syndrome. Then follows the discovery of the association of that syndrome with cataract, either in the patients themselves, or in members of earlier generations of their families. Later, it was recognised that dystrophy, myotonia, and cataract alike are some only of the manifestations of a great heredo-familial malady, other signs of which are changes in the thyroid gland, testicular atrophy, baldness, increase of sweat and tears, and cyanosis and coldness of the extremities. The muscular dystrophy and myotony have in the observed cases been limited to the collaterals of one generation of a family, seldom developing before the age of 25, but cataract has been traced back through four or five generations. Moreover, as is not infrequently the case with abiotrophies, the signs tend to appear earlier in members of the later generations.

Some recent investigators hold that the underlying factor in the disease under discussion is a widespread defect of the endocrine glands, and that we are here confronted with a pluriglandular syndrome. It may well be that other affections of this group, the abiotrophies, will prove to be local manifestations of much wider maladies; and that the link between the calcareous deposits and the digital anomalies in myositis ossificans may be found in a generalised defect of the mesenchymatous tissues, of which these are merely the most conspicuous signs.

Let us turn now to the consideration of a very rare and curious disease which was first described by Gaucher in 1882, and goes by his name.[6] He described, under the title of primary epithelioma of the spleen, a form of enlargement of that organ, met with in a child, and characterised by the presence, in the splenic tissue, of numbers of large hyaline cells which stain but feebly. The microscopic picture is alike in all cases of the malady and is quite distinctive. Before long it was realised that this was no form of malignant growth, and that the changes were, by no means, limited to the spleen. The liver becomes greatly enlarged; the hæmopoietic tissues generally, including the bone-marrow are involved; and the peculiar Gaucher cells are found in all the affected parts. Beginning in infancy the disease is in the highest degree chronic, and continues on its snail-paced course through decades of the patient's life. It is wont to occur in several children of a family whose parents are not affected, but consanguinity of the parents has not been recorded. A large majority of the sufferers have been females.

In recent years it has been shown that the Gaucher cells owe their peculiar swollen and hyaline appearance to the presence in them, in quantity up to 10 per cent. of the dried spleen, of a chemical substance which has not been found in normal splenic tissue. This substance, kerasin, is allied to cerebrin, and is a member of the class of galacto-lipins. Whether the kerasin, as such or a more complex compound of which it is a constituent, is formed in or deposited in the Gaucher cells has not yet been determined. Pick, one of the most recent writers on the subject, holds that Gaucher's disease is due to an inborn error of metabolism, but thinks it probable that here the metabolic process is perverted, and not merely interrupted at an intermediate stage; in other words, that kerasin is a product of abnormal metabolism. He points out that in diabetes a deposition of abnormal chemical materials occurs in the reticulo-epithelial tissues.

Here again we may trace the successive stages of the elucidation of the nature of a rare malady, fraught with important pathological lessons. The subject of such maladies as the abiotrophies and Gaucher's disease furnish striking examples of constitutional liabilities. It is because they are uncommon individuals that they are predestined to suffer. In other words, the patient rather than the malady is rare.

I trust that the few examples which have been quoted will suffice to show how much has been learned from the study of Nature's experiments, and even that they are in some instances more instructive than our commoner ailments. But my chief object is not to show how much has been accomplished, but to urge the continuance of work on these lines; seeing that there are many rare maladies the lessons of which have been learnt only in part, or have not yet been learnt at all. Yet when we compare them with those of which I have already spoken, we cannot doubt that they "might become the beginning of excellent knowledge"; and even whilst their problems are still unsolved, they offer many points of interest.

For example, the syndrome known as intermittent hydrarthrosis has features which may be described as uncanny. Effusion into one or both knee-joints, and only seldom into other articulations, recurs with regularity comparable to that of some forms of malaria, but which is clearly not connected with the life-history of any parasite. The period varies in different cases, but apart from slight progressive postponements or anticipations, remains constant for the individual case. From the commencement of one attack to that of the next, a common interval is from six to eight days, and the usual duration of an attack is about three days. So the patient can

predict with accuracy the dates of future attacks nd make arrangements accordingly.

Obviously the trouble is not primarily in the oints, for they are usually normal between attacks. loreover, energetic local treatment of an affected nee may cause the hydrarthrosis to transfer its ttentions to the other, and the attacks cease uring a pregnancy to return after delivery.

An exactly similar periodic hydrarthrosis is sometimes met with in cases of arthritis of various kinds. he distension of the joint with fluid recurs at regular ntervals, but the clinical picture is blurred by the ailure of the joints to recover between the attacks. chlesinger,[7] who has studied this affection for many ears, does not include these secondary cases in the ame category as the primary ones, but I cannot see ny sufficient grounds for excluding them.

It was Schlesinger who originally suggested that he hydrarthrosis was a kind of *hydrops hypostrophos*, nd more and more evidence has been produced n favour of its anaphylactic nature. In some cases he attacks have coincided with transient swellings f the lips or eyelids, in others with forms of urticaria, nd in others with asthma, but not always simulaneously with the joint trouble. They may alternate, nd one patient said that she preferred to have asthma n her knees rather than in her lungs. In a few cases esensitisation by small injections of protein have een tried with encouraging results, but they are too ew as yet to be conclusive.

There is undoubtedly a connexion between the utaneous lesions of the erythema group and affections f the joints. For evidence we need not seek further nan the familiar serum sickness, and Henoch's urpura, erythema nodosum, and even rheumatic fever ell the same tale. Again, periodicity is met with in ther maladies of the anaphylactic group, in rythemata occasionally, in asthma often, and in lenoch's purpura almost always. The periodic omiting of children also is probably another member f the group. But in none of these other conditions, ith the possible exception of the last, is there any uch accurate periodicity as in hydrarthrosis. The ost likely explanation would appear to be that each ttack desensitises the patient for a time, at the xpiration of which the trouble recurs. As long ago s 1868, Salter, in his book on asthma, written long efore sensitivity to proteins was dreamed of, suggested nat the periodicity in some cases of that disease nd the apparent immunity in the intervals might e due to the accumulation of an unknown something etween attacks and its discharge during the attack. le mentions that "for some time after an attack, the me varying according to the interval characteristic t that particular case, the patient may expose imself to the ordinary exciting causes of the aroxysms without the slightest fear of inducing one." nd that was written 60 years ago!

When we review the outcome of the study of ntermittent hydrarthrosis up to now, we realise nat its lessons are only half learnt, and that it has ill more to teach us.

This is even more true of the very uncommon ndrome known as sulphæmoglobinæmia.[8] No orbid condition asks more clearly Paget's questions: Why is this rare? and, being rare, why did it in is instance happen?" It is clearly an acquired alady, with no indication of family or hereditary currence. The presence in the red corpuscles of ie compound sulphæmoglobin produces a somewhat eculiar kind of cyanosis, similar to that due to the lied methæmoglobinæmia. The investigation of this ndition, by its discoverer Hijmans van den Bergh nd others, has brought to light a number of interesting cts, but its chief problems still await solution. is clear that the presence of sulphæmoglobin in the lood is not due to any excess of hydrogen sulphide the circulation, and in cases of poisoning by ydrogen sulphide it is not observed. Given certain conitions the normal trace will suffice. The formation of ulphæmoglobin is favoured by the presence of certain hemical substances, notably reducing agents such as hydrazine, in the blood, but it does not occur, even with hydrazine, if oxygen be completely excluded. Snapper has shown that prolonged administration of phenacetin, in doses too small to induce methæmoglobinæmia, can give rise to sulphæmoglobinæmia.

In some cases a nitrifying bacillus has been found in the saliva, and in some in the fæces; whereas in other cases no such organism has been found. Whatever be the conditions necessary for this compound of hæmoglobin to be formed in the blood, they can very rarely be fulfilled, for the malady is decidedly uncommon. If it be an infective disease, it is remarkable that the cases should be so few and so widely scattered, which would suggest that the bacillus in entering the human organism had missed its true vocation.

Another example of a rare malady which presents important unsolved problems is chloroma. A great advance was made when it was recognised that the remarkable green tumours, with their curious distribution, were associated with a form of leukæmia. The clinical picture, the tumours upon the skull, and the exophthalmos caused by tumours in the orbits, might be described as characteristic of chloroma were not a practically identical picture presented in cases of left malignant hypernephroma. The two diseases have only this in common; the similarity depends upon the distribution and not on the nature of the lesions, and the distribution is apparently due to spread along lymphatic channels and the thoracic duct. We do not know why tumours, with such distribution, should develop in this variety of leukæmia and the nature and origin of the highly unstable pigment which imparts to them their green colour is still obscure. It certainly is not a bile pigment, and is more like a lipochrome; but as I can testify, the investigation of it is beset with great difficulties.

I should have liked, had time permitted, to have spoken of that malady involving the bone-marrow, of which the copious excretion of the Bence Jones protein is a diagnostic sign, for it is one of the most obscure of rare diseases. Again that weird mixture of infantilism and premature senility which Hastings Gilford described under the name of "progeria," and the developmental anomalies of bony structures, of which achondroplasia, oxycephaly, and hypertelorism may be cited as examples, have not yet revealed their secrets, but may be expected to repay investigation in course of time.

It would be easy to mention many other conditions which offer like problems; but I do not think that it is necessary to adduce any more examples to prove my point. Those which have been chosen may be looked upon as representative. They have been selected from widely different regions of the province of medicine, and, for the most part, have nothing in common save their rarity and their instructiveness. Yet all of them, to quote Paget once more, "have that kind of attraction which belongs to everything which excites wonder," and each brings its particular contributions to the sum of knowledge. All alike tend to prove the truth of Harvey's dictum, that "Nature is nowhere accustomed more openly to display her secret mysteries than in cases where she shows traces of her workings apart from the beaten path."

We may feel sure that, in the future as in the past, there will be many who will try to solve the problems of the commoner diseases, the control of which is of such vital interest to the community at large. Let us hope that there will always be some who will seek to guess the riddles and to learn the lessons of the rarer maladies.

RELAPSES IN SCARLET FEVER.

By A. H. G. BURTON, M.D. Lond., D.P.H.,
MEDICAL OFFICER OF HEALTH, ILFORD;
AND
A. R. BALMAIN, M.B. Lond., D.P.H.,
CHIEF ASSISTANT MEDICAL OFFICER OF HEALTH, ILFORD.

During the past 21 months all cases of scarlet fever admitted to the Ilford Isolation Hospital (432 in number) have been treated with concentrated scarlet fever antitoxin. We propose at a later date to analyse the results which have thus been obtained. For some time we have observed that the occurrence of true relapses of scarlet fever appeared to be more frequent (the percentage relapse rate on the 432 cases was 4·16) and therefore it was decided to apply the Dick test to: (1) all scarlet fever patients in the wards on a certain date; (2) all these cases at weekly intervals; and (3) all new cases on admission and at weekly intervals after their admission.

The text-books give the impression that true relapses in scarlet fever are very rare and of little practical importance. In some of the books confusion appears to exist in the figures, and insufficient attention appears to have been paid as to whether or not the patient had a typical attack of scarlet fever on admission. As a matter of fact relapses are of considerable administrative importance. When a relapse occurs the general practitioner is often blamed for sending a patient into an isolation hospital only to contract scarlet fever there, when in fact his original diagnosis was a correct one and a relapse of the disease has occurred. The percentage of relapses given by various authors is as follows: Scholes (Melbourne), 0·35 per cent.; Rolleston, 1 per cent.; Ker, 1 per cent.; Caiger, 1·1 per cent.; Goodall, 1·53 per cent.; Ker and Rundle. 2 per cent.; while Box quotes figures varying from 0·5 to 7 per cent.

It would appear from this that a true relapse-rate of between 1 and 2 per cent. might be taken as a fair average; the 7 per cent. rate quoted by Box probably includes cases which cannot come under the definition of true relapses.

Table A shows the relapse percentage-rate in 13 hospitals of the Metropolitan Asylums Board during 1914, calculated from the figures supplied in the M.A.B. report for that year. Those hospitals which are marked with an asterisk received large numbers of transfers of convalescent cases from other hospitals. In view of the conclusions which we have come to as regards the causation of a relapse in scarlet fever it is interesting to note that the relapse-rate in these three hospitals is considerably higher than in the others.

In 1891 Boddie[1] brought a communication before the Medico-Chirurgical Society of Edinburgh, describing two home-nursed cases of scarlet fever, which had relapsed. These have been quoted as cases of auto-infection, but it is not clear, on reading the cases, that reinfection could be entirely excluded.

In the discussion which followed, some speake held the view that relapses occurred only during t second and third week. This is not the view n generally held, and probably the so-called relaps which took place at these periods were really prima attacks. True relapses are very uncommon bef the fourth or fifth week. Boddie, in a review the literature of the subject, mentioned that so writers described relapses and "pseudo-relapses It would seem probable, however, that the latter a due to some intercurrent infection, such as rubel If relapses occur in home-nursed cases of scarl fever they must be extremely rare, for Dr. D. Kirkhope, M.O.H. for Tottenham, whose experien in nursing cases of scarlet fever at home is probab unique, has informed us that between April, 192 and December, 1927, 2383 cases of scarlet fever h been treated at home at Tottenham and in no instan had there been a relapse.

Dick Tests in Acute Cases of Scarlet Fever.

For the purpose of this article the term "relapse is taken to mean a repetition of the attack, includi rise of temperature, punctate erythema, congest fauces and peeling tongue, occurring during t convalescence of a patient from a primary atta of scarlet fever. This investigation has been ma as an aid to the elucidation of the problem and t relationship of relapses to immunity in the disea The Dick test was performed in 93 consecutive cas and the results of the tests compared with those later dates. The whole series were given 10 c.c of concentrated scarlet fever antitoxin serum int muscularly on admission, with the exception of th cases, one of which received 5 c.cm., one 10 c.c (and a further 10 c.cm. when the relapse occurre and a third 20 c.cm. New cases admitted after t investigation commenced were given the serum fo hours after the Dick test was done. The test w read at the end of 24 hours, a definite erythema ¼ in. or over being read as "positive," and t results classified as: (*a*) negative, no erythema; erythema of ¼ in.–½ in.; (*c*) erythema, ½ in. or over.

Table II. gives a comparison with the results of ther workers. It will be noticed that whereas the erum-treated cases showed a percentage of strongly)ick-positive results during the third, fourth, fifth, nd sixth weeks of 13·3, 26·9, 16·3, and 18·7, the on-serum treated cases showed a much less number f strongly positive results.

Okell and Parish,[2] in testing 120 convalescent carlet fever patients, and reckoning all reactions as ositive, found that 18 per cent. of convalescent atients give a Dick-positive reaction. It will be bserved from Table I. that the serum-treated cases howed a much higher percentage than this. Okell and 'arish found it difficult to explain the results which hey had obtained, and gave four explanations: (*a*) hat the present methods of diagnosis are not wholly atisfactory; (*b*) that patients who have had scarlet ever do not necessarily become immune to the toxin r become so, in some cases, very slowly; (*c*) that trains of scarlet fever streptococcus may produce iore than one toxin; (*d*) that the test is not a true ndication of susceptibility to scarlet fever. On the 'hole, they were inclined to consider that (*b*) was the robable explanation. O'Brien[3] has suggested that)ick-positive reactors during convalescence from carlet fever may have cured themselves of their ever by producing antitoxin which is still locked up ntracellularly, and that the cells are slow to excrete he antitoxin into the blood stream. We would uggest, however, that the Dick-positive reactors in onvalescent scarlet fever cases are persons who have ailed to develop immunity.

It will be noticed in Tables I. and II. that the establshment of immunity in scarlet fever does not follow straight line. It has been suggested by O'Brien hat the use of antitoxic serum may delay the evelopment of immunity during convalescence. Ve would go further than this, however, and state hat, according to the results given above, in certain ndividuals immunity does not develop at all. In 'able B are given examples showing failure in the evelopment of immunity in cases other than those vhich showed a relapse.

This variability in the individual immunity produced by an attack of scarlet fever may depend upon ither: (*a*) the virulence or type of the primary nfecting *Streptococcus scarlatinæ*; (*b*) the individual ower of resistance to this type of antigen; or (*c*) he interference with the formation of antitoxin by he patient's own cells, caused by the initial adminisration of antitoxic serum.

* Repeat test.

We append below particulars of the 18 true relapses which occurred at the Ilford Isolation Hospital in the 432 cases reviewed. (Table III.)

It is notable that:—

1. The majority of relapses occurred in young children. Whether this fact is of any practical importance or not cannot be stated, as the greater proportion of the cases admitted to hospital occurred during childhood.

2. Only 6 complications developed after the primary attack in these cases compared with 23 complications which occurred after the relapses.

3. The majority of the patients were up and in the convalescent ward at the time of the relapse.

4. Thirteen of the relapses took place between the twenty-second and fifty-first day. Only one occurred before the beginning of the fourth week.

5. The Dick test was found in four cases to be negative at various periods after the relapse and to remain negative. In three cases it was positive before and after the relapse. In one case the immunity varied after the relapse.

A short account of two cases (13 and 16) is not without interest, as the Dick test was strongly positive before the relapse in both cases.

Case 13 was a girl aged 8, who was admitted with a well-marked attack of scarlet fever, strawberry tongue, and some rhinitis. Nasal swabs were taken which were negative for the Klebs-Löffler bacillus. The temperature was 103·6° on admission. She was given 10 c.cm. of scarlatinal serum. She developed slight cervical adenitis and, in view of the nasal discharge, was nursed by the "barrier" system. At the end of the third month of her stay in hospital the Dick test was positive for three consecutive weeks. Her rhinitis having cleared up, the "barrier" was discontinued, and she was allowed to be up in the convalescent ward. It was decided, however, in view of the persistent Dick-positive result, to give her a further injection of scarlatinal serum to induce a more prolonged immunity. This was done, but too late to prevent a relapse, because in the afternoon of the same day that the serum was administered she developed the typical scarlet fever rash, temperature of 99·8°, and later a strawberry tongue. In fact, when the serum was given she showed signs of a commencing relapse. Five days after this attack her Dick test was negative, and a week later it was again negative. For three subsequent weeks after this the Dick test was positive; on the last occasion an erythema of 1½ in. was noted, showing that she had again failed to develop natural immunity to scarlet fever. The existence of persons of this kind was recognised many years ago by Foord Caiger, who described one young woman who had three distinct attacks of scarlet fever within a period of three months, in the last of which she died.

Case 16 was a boy aged 7, who was admitted with a typical attack of scarlet fever, temperature 101°, and was

given 10 c.cm. of scarlatinal serum on admission. A fortnight after this the Dick test was positive, although the patient was desquamating freely, and it remained positive for three weeks. During this period the boy was being nursed in a side ward and strictly "barriered." At the end of this period he had to be removed into the main ward, where he was still "barriered," but seven days later he developed a typical scarlet fever rash, with a temperature of 103·6° and strawberry tongue. The Dick test showed pallor over the previous positive area. On three consecutive weeks following the relapse the Dick test was negative,

Conclusions.

1. It is necessary to Dick test cases of scarlet fever admitted to an isolation hospital if relapses are to be avoided. In view of the fact that relapses are uncommon before the fourth week, it would appear that a Dick test should be performed at the end of the third week after admission to hospital.

2. It is unjustifiable to retain cases of scarlet fever in a general ward who give a marked Dick-

showing that this boy had apparently now developed active immunity to scarlet fever. Following this, however, the boy gave a Dick-positive reaction in the two succeeding weeks. He belonged apparently to the same class as Case 13, his immunity being of a fleeting character.

Gunn, in the M.A.B. Report for 1926–27, states that not infrequently a patient suffering from a mild attack of scarlet fever may still have weakly positive or doubtful Dick reaction at the end of six or seven weeks and that, while most of the cases were discharged in this state, in some few instances they developed a second attack of scarlet fever and subsequently became completely negative Dick reactors. He associates himself with the view that reinfection with a different strain of scarlatinal streptococcus is the cause of the relapse. There does not, however, appear to be any evidence for this, and a true relapse appears to be due to an insufficient immunity conferred by the original attack. The two cases which have been quoted in some detail substantiate this view of the question.

Zingher, out of 232 patients, found that only 8·7 per cent. gave a positive Dick reaction during convalescence from scarlet fever.[7] It is well known that Zingher found a higher percentage of positive results in the first few days of the disease than other workers have done.[8] This is due to the fact, however, that he included as positive results all grades of reaction, as will be seen from his original paper.

positive reaction during their convalescence. Suc cases should be either (*a*) treated in separation wards or (*b*) immunised during the rest of their stay i hospital, or (*c*) isolated at home for the remainder c their convalescence.

3. Scarlatinal serum appears to have the definit effect of increasing the number of Dick-positiv reactors during convalescence, and in any hospita in which the serum is given on a large scale the step mentioned in 1 and 2 are most important.

4. There appears to be a definite class of individual whose blood is unresponsive to the toxin of scarle fever in the production of antitoxin, and while suc cases recover from a mild attack of scarlet feve they are liable to a relapse or to have two or mo attacks. It will be an interesting point to investigat whether certain patients who have had scarlet feve and who are insusceptible to its toxin are sti susceptible to the local bacterial action of th streptococcus, as, from the work of Kinloch, Smit and Taylor, appears to be the case in persons wh have been immunised by scarlet fever toxin. If th is so it would explain the late septic complicatio of scarlet fever, particularly rhinitis, which is suc a frequent cause of the prolonged stay of patien or, if they are discharged too early, the productic of return cases.

5. The results emphasise again the necessity convalescent wards. Altnough most of the relaps

ecorded occurred in convalescent wards, there is o doubt that if the cases had been treated in conunction with acute cases throughout their illness ne number of relapses would have been markedly ncreased. We are investigating this point further. wabs from the throats of 21 patients in a convalescent ard showed that one patient was carrying *Streptoccus scarlatinæ*, type 2, 30 days after onset of tack and was still a carrier when tested after scharge from hospital 12 days later.

6. Relapses in scarlet fever are primarily due to ck of immunity in a patient. A relapse may be used in such patients either: (*a*) by an autofection from the virus still present in the patient's ody, as suggested by Caiger, or (*b*) by cross-infection ith the same type of *Streptococcus scarlatinæ* as iginally infected the patient, or (*c*) by cross-infection ith another type of *Streptococcus scarlatinæ*.

There are a considerable proportion of Dick-positive reactors during convalescence from scarlet fever and a number of these reactors relapse. Relapse does not, as a rule, occur until the fourth week, and it would appear that in the majority of cases the explanation (*b*) is the most probable one.

NVESTIGATION OF A SERIES OF CASES OF SECONDARY ANÆMIA

TREATED WITH LIVER OR LIVER EXTRACT.

BY JANET VAUGHAN, B.M., B.CH. OXF.

From the Department of Clinical Pathology, University College Hospital.

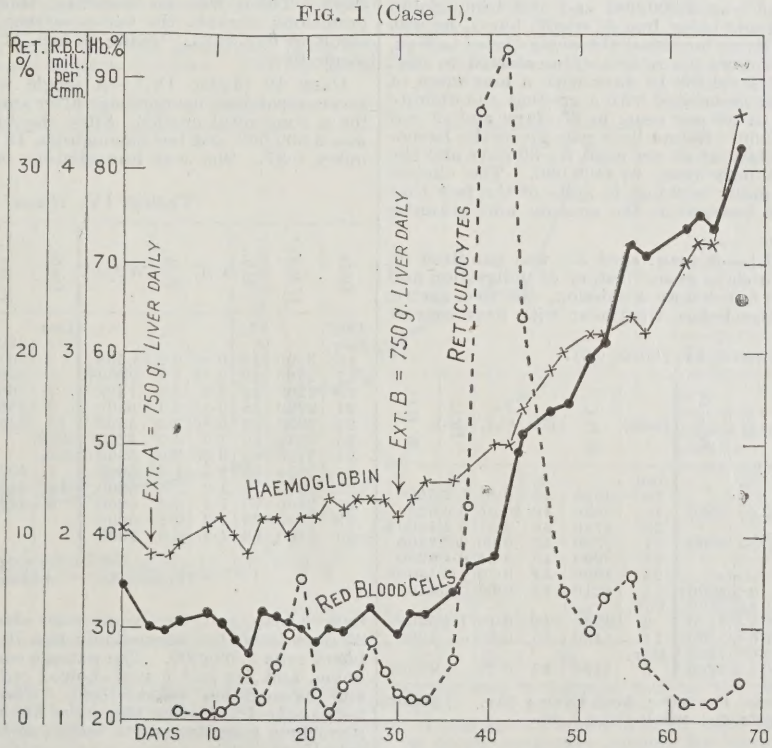
SINCE Minot and Murphy published in 1926 their st paper on the liver treatment of pernicious æmia all additional evidence has strengthened tneir aim to have found in liver or liver extract a rapid eans of combating this disease. The position as gards secondary anæmias is, however, far less clear. ery few cases have been published [1] and in no case ave full details been given. The general consensus opinion seems to be that liver is only useful in rnicious anæmia. This is surprising in view of the ct that the mediate cause the application of a liver et to pericious anæmia as the starting result btained by Whipple [2] in so eating secondry anæmia exerimentally roduced in ogs.

A series of ses recently vestigated at niversity College Hospital ggests that, at ny rate in cerin types of econdary æmia, liver, ther whole or the form of xtract, may be efinitely valuble. The cases ll into three oups: (1) pericious anæmia; 2) anæmia econdary to æmorrhage; 3) anæmias ssociated with rcinoma, and anæmias of unknown origin unssociated with any apparent hæmorrhage.

The 13 cases of pernicious anæmia have been briefly mmarised [3] and a full report of them will appear later. Five were treated with liver extracts and the response to these was by no means uniform, as in the following instance:—

CASE 1.—Typical clinical and pathological findings. The patient was given extract A, equivalent to 750 g. of fresh liver a day, for 12 days. There was no response and the dose was increased to an equivalent of 1250 g. a day for six days, again with no result. Extract B in a dose equivalent to 750 g. was then given, and five days afterwards the reticulocytes started to rise, reaching a maximum of 36 per cent. on the eighth day. Twenty-six days later the red cell count had risen from 1,740,000 to 4,130,000 and the hæmoglobin from 41 per cent. to 86 per cent. (Fig. 1).

FIG. 1 (Case 1).



The remaining eight cases of pernicious anæmia were treated with whole liver and the results bore out the claims of other investigators as to the general improvement in the blood picture. Nevertheless this still presented a few abnormal features. The colour-index, in all but two cases, remained above 1, and in the early stages of improvement an index as high as 1·4 was found so often as to be almost typical. This cannot in any way be associated with the iron content of the liver as it was found in cases treated with extract as well as in those on whole liver. The leucopenia was persistent in those cases in which it was originally present. Three out of the 13 cases showed a lag in reaction, for which no reason appeared except in Case 5, where there was a negative indirect van den Bergh reaction at the start. Two of Fraser's [4] non-reacting cases also showed a negative indirect van den Bergh reaction. One of them died and the post-mortem findings were compatible with a diagnosis of pernicious anæmia; which controverts Minot's suggestion that cases which do not show a prompt response are not pernicious anæmia. The improvement in the subjective symptoms of shooting pain and tingling has been

definitely associated with a change to a far more genial outlook on life.

Anæmia Secondary to Hæmorrhage.

Two cases of secondary anæmia due to hæmorrhage were treated with extract. One was given both liver and extract and four took whole liver.

CASE 14.—A man, aged 34, was admitted on Jan. 23rd, 1928; he had a gastric ulcer and had twice vomited a pint of blood, 16 days and again four days before admission. On Feb. 21st the stools were free of occult blood and thereafter he was given 8 oz. of whole liver daily for 25 days. The hæmoglobin remained steady at 50 per cent.; the red blood cells rose from 3,080,000 to 4,100,000, in contrast with a rise of only 200,000 in the 29 days before liver was given. There was never any reticulocyte response. Clinically his condition improved and he gained weight.

CASE 15 (Table I., Fig. 2).—A married man, aged 49, was admitted on Jan. 3rd, 1928, after three attacks of hæmorrhage in the preceding three weeks due to a gastric ulcer. Red blood count 1,800,000; hæmoglobin, 28 per cent.; colour-index, 0·77. A month later, on ordinary treatment,

the red blood count was 2,200,000 and the hæmoglobin 30 per cent. The stools being free of occult blood, he was given 4 oz. of whole liver, increased three days later to 8 oz. At the end of seven days his reticulocytes started to rise, maintaining a raised level for 18 days with a maximum of 9 per cent. This was associated with a gradual and definite rise in hæmoglobin to 58 per cent. in 33 days and of red blood cells to 4,180,000. Before liver was given the hæmoglobin had been constant at 30 per cent. for 30 days and the red blood cells had only risen by 400,000. The clinical improvement was equally striking, in spite of the fact that tubercle bacilli were present in the sputum and granular casts in the urine.

CASE 16 (Table II.).—A man, aged 35, was admitted on Jan. 27th, 1927, with eight years' history of indigestion and hæmatemesis on the day before admission, due to a gastric ulcer. In the 33 days before treatment with liver extract

his hæmoglobin rose from 20 to 30 per cent. and his red blood cells from 1,370,000 to 3,000,000. He had had iron and arsenic for 18 days. He was then given extract C, in a dose equivalent to 500 g. fresh liver, for 16 days. His hæmoglobin went up to 40 per cent. and his red cells to 3,700,000. Eight ounces of whole liver were then substituted for the extract, and in a further period of 15 days his hæmoglob rose to 44 per cent. and his red blood cells to 4,200,00 He at once began to gain weight and put on 9 lb. in a fo night. He has continued to eat liver at home, and his la count, on March 5th, showed 5,440,000 red blood cells a hæmoglobin 68 per cent.

CASE 17 (Table III., Fig. 3).—A man, aged 49, was admitt on Dec. 16th, 1927, with a long gastric history includi hæmatemesis due to a duodenal ulcer three days befor In the 25 days after admission, although he had had arsen for the last 12 days, his hæmoglobin only rose from 46

50 per cent. and his red cell count was unaltered. He w then given a dose of a non-commercial extract (E) equivale to 472 g. of fresh liver a day. In 16 days his hæmoglob rose to 64 per cent. and his red blood cells from 2,800,0 to 4,100,000, a striking increase of over 1,000,000 compar to the preceding period when there was no alteratic There was no increase in the reticulocytes.

CASE 18.—A man, aged 32, with a gastric ulcer, w admitted on Feb. 20th, 1928; he had brought up a pint blood 12 weeks previously. In the 18 days after admissi his red cell count had only risen by 300,000 and his hæm globin had remained stationary. He was given a dose extract C equivalent to 750 g. of fresh liver daily for sev days. There was no response, though in two cases pernicious anæmia the same extract has given a defin result in five days. Owing to lack of extract he is now whole liver.

CASE 19 (Table IV.).—A single woman, aged 24, h severe secondary hæmorrhage after amputation of the cer for a congenital erosion. After the bleeding her red cou was 2,360,000 and her hæmoglobin 48 per cent., and colo index 0·87. She was immediately put on 8 oz. of wh

liver a day and her count rose steadily. On discha 25 days later, her hæmoglobin was 76 per cent. and her blood cells 3,560,000. The patient continued to eat live home, and her last count showed red blood cells 4,900, and hæmoglobin 86 per cent. Though the colour-in was above 1 for some time, the films in no way sugges pernicious anæmia, and a test-meal showed normal gas secretion.

CASE 20.—A married woman, aged 39, had bilat general thrombosis and constant pyrexia after a p hysterectomy for severe menorrhagia. She was anæn red blood count 2,800,000, hæmoglobin 34 per cent., colour-index 0·55. During this period she was put

oz. of whole liver, which she took well for 20 days, but ithout response.

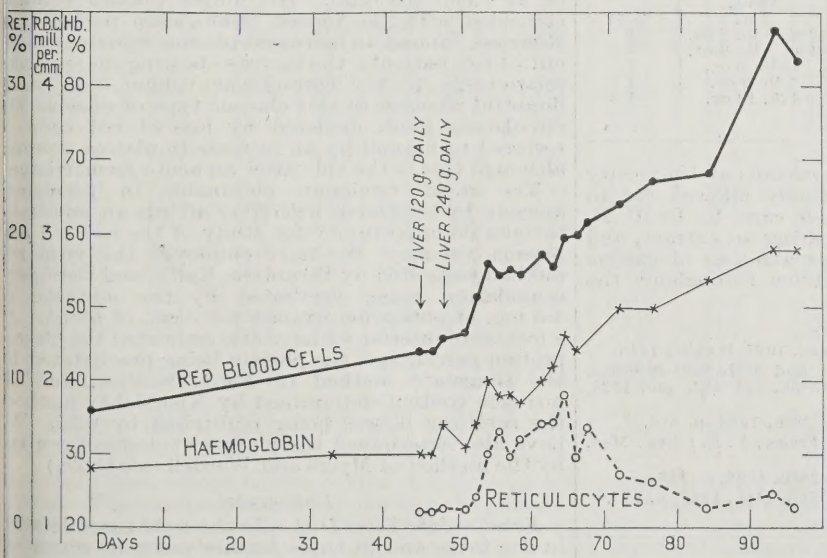
In none of the five gastric cases was there any omplaint of pain or discomfort on taking the whole ver or extract, as might perhaps have been expected om patients taking as much as 8 oz. of meat one ionth after hæmorrhage. Fractional test-meals on normal individual, comparing a plain milk meal ith a milk meal containing a single dose of extract, owed that the addition of the extract made no ppreciable alteration in the acid secreted. There eems therefore to be no contra-indication to treating astric cases in this way. The results in Cases 15 and 7 are striking. In the first there was an increase of 8 per cent. in the hæmoglobin and an increase in the ed cells of 2,000,000 in 33 days, as compared with n increase of 400,000 in the month before liver was iven. In the second there was an increase of over ,000,000 in the red cells, compared with complete bsence of reaction before extract was given, while he hæmoglobin went up by 14 per cent. (see Fig. 3). his marked response shows that improvement in econdary anæmias is not due to the iron content of ver, as the extract is free from iron. A point of articular importance is the reticular rise in Case 15, s this has hitherto been considered peculiar to the esponse of pernicious anæmia. The fact that the other ases started at a level above 3,000,000 may explain ne absence of increase in the reticular count, as the eticulocyte crisis is less marked in cases of pernicious næmia starting treatment at this height. It is erhaps not fair to claim Case 19 as a success, since o long control period was allowed before starting eatment. It has been reported, however, because shows that there may be considerable increase in one-marrow activity without any appreciable lteration in the reticular count.

Anæmias Unassociated with Hæmorrhage.

The following five cases do not fall conveniently nto any group, but seem worth recording to supple- ient the scanty data at present available of the effect f liver in such conditions.

CASE 21.—A man, aged 55, with aleukæmic lymphatic eukæmia. Wassermann reaction positive. Van den Bergh

FIG. 2 (Case 15).

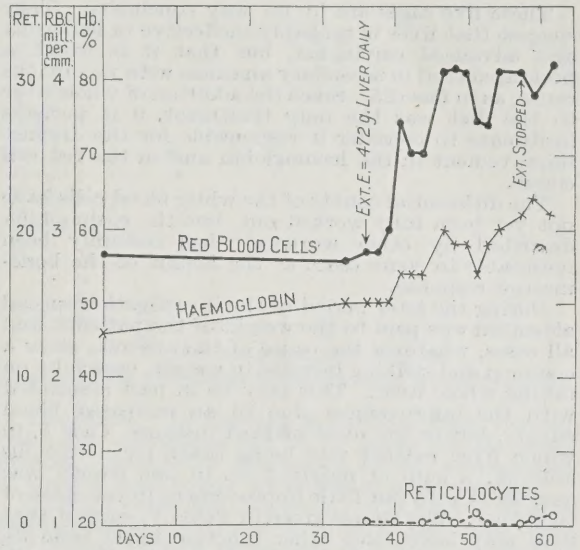


ndirect reaction positive. Total achlorhydria. Blood film howed anisocytosis with an increase in size of the red ells compatible with pernicious anæmia. Red cells, ,990,000; hæmoglobin, 62 per cent.; colour-index, 1·02. White blood cells, 7000; lymphocytes, 88·5 per cent. As diagnosis of pernicious anæmia was at first thought possible e was given extract D in doses equivalent to 750 g. of fresh iver for 13 days. There was no appreciable alteration in the æmoglobin or the red cell count, and the white count fell o 1500.

CASE 22.—A case of probable lymphatic leukæmia associated with Bence-Jones albuminuria. Van den Bergh reaction indirect positive. Wassermann reaction negative. Red blood cell count, 1,780,000; hæmoglobin, 30 per cent.; colour-index, 0·88. He was fed on 8 oz. of whole liver daily for a fortnight. There was no response.

CASE 23.—A man, aged 60, with carcinoma of the prostate and secondary deposits in bones. Admitted with

FIG. 3 (Case 17).



a history of increasing anæmia, loss of weight, and indigestion for eight months. He had been treated with whole liver previously, as he was thought to be a case of pernicious anæmia. Wassermann reaction negative. Van den Bergh indirect reaction negative. Total achlorhydria. X rays of the stomach showed no evidence of growth. Red blood cell count, 1,860,000; hæmoglobin, 36 per cent.; colour-index, 1·0. White blood cell count, 5500. Differential white count showed constant presence of myelocytes and the size of the red cells was incompatible with a diagnosis of pernicious anæmia. He was given whole liver for 12 days but the blood picture remained unaltered. Later he was given extract C for 12 days in a dosage equivalent to 500 g. of fresh liver a day. The blood picture remained constant.

CASE 24.—A man, aged 49, was admitted on Jan. 23rd, 1928, with nervous symptoms which at first, in view of his blood count and test-meal result, were thought to be compatible with a rather atypical form of subacute combined degeneration of the cord. Further investigation favoured a diagnosis of syphilitic spastic paraplegia. Wassermann reaction positive. Van den Bergh indirect reaction negative. Total achlorhydria. Red blood cells, 3,900,000; hæmoglobin, 84 per cent.; colour-index, 1·08. White cells, 7700; film compatible with a diagnosis of pernicious anæmia, though in no way striking. He was given 8 oz. of whole liver daily for a fortnight. There was no rise in the red blood cells or the reticulocytes, and a definite fall in the hæmoglobin to 70 per cent.

CASE 25.—A single woman, aged 32, admitted as a case of severe secondary anæmia for investigation. She gave a six years' history of anæmia and weakness, and complained of piles, but no evidence was found on investigation to support this as an explanation of the blood picture. No menorrhagia, no blood in the stools, no source of sepsis detected. Total achlorhydria. Wassermann reaction negative. Positive indirect van den Bergh reaction. Red

blood count, 4,600,000 ; hæmoglobin, 37 per cent. ; colour-index, 0·4. White blood cells, 7000. Films typical of a severe secondary anæmia. She was given 8 oz. of whole liver for 18 days. There was no change in the blood findings and she went home. A month later, having continued the liver diet, she looked and felt much better, and her red blood cell count was 5,830,000, with hæmoglobin 56 per cent. and white blood cells 4800. There was thus an increase of over 1,000,000 red cells and 20 per cent. in the hæmoglobin. Van den Bergh indirect reaction positive.

These five cases are in no way conclusive They suggest that liver is probably ineffective in leukæmia and advanced carcinoma, but that it is worth a prolonged trial in secondary anæmias with no obvious cause, as in Case 25. Since the addition of whole liver to the diet was the only treatment, it is perhaps legitimate to consider it responsible for the distinct improvement in the hæmoglobin and in the red cell count.

The differential counts of the white blood cells have not yet been fully worked out, but the eosinophilia described by other workers[5 6] has certainly been noticeable in some cases at the height of the bone-marrow response.

During the later period of the investigation special attention was paid to the weight of the patients, and all cases, whatever the cause of the anæmia, show a common and striking increase in weight, especially on taking whole liver. This may be in part associated with the improvement due to an increased blood supply, but in the most marked instance, Case 5, in which liver extract was being taken for pernicious anæmia, a gain of nearly 2 st. in one month was associated with but little improvement in the state of the blood. The figures given in Table V. suggest that liver may have some other function apart from its action on blood formation. At any rate it seems worth trial in cases of loss of weight that do not react to the more usual measures.

TABLE V.

Case.	Disease.	Treatment.	Weight gained.	Time in months.
1	Pernicious anæmia.	Extract.	12 lb. 1 oz.	1
2		,,	3 lb. 2 oz.	1

13		,,	1 st. 5 lb. 6 oz.	1
14	Secondary anæmia.	,,	15 lb. 6 oz.	1
15		,,	7 lb. 9 oz.	1
16		Extract and whole liver.	8 lb. 13 oz.	1

My thanks are due to the physicians at University College Hospital, who have kindly allowed me to investigate the cases under their care, to Dr. C. R. Harington for his help in preparing an extract, and to Dr. G. W. Goodhart for his analyses of gastric contents and his constant advice throughout the investigation.

TIDEMILLS MARINE HOSPITAL.—A new wing of this hospital for crippled boys at Bishopstone, Sussex, has been opened by Mrs. Warren, the donor. The extension includes wards, solaria, workshops, playroom, electric and artificial light departments. The hospital is an annexe of the Heritage Craft Schools at Chailey, and is situated on the beach in the bay between Newhaven Harbour and Seaford. The original buildings were the gift of Colonel Warren and had accommodation for 36 crippled boys ; 70 can now be taken.

THE BLOOD AND PLASMA VOLUMES IN PERNICIOUS ANÆMIA.

BY O. L. V. DE WESSELOW, M.B. OXF., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL ;
AND
J. BAMFORTH, M.D. LIVERP., M.R.C.P. LOND.,
ASSISTANT DIRECTOR OF PATHOLOGY AT THE HOSPITAL.

WHILE studying the effect of the Minot-Murph liver diet in pernicious anæmia, we have had occasio to estimate the blood and plasma volumes in certai of our patients. Such estimations are of som importance in determining the results of treatment i the anæmias, since changes in the red cell count ma be produced as readily by variations in plasma volum as by actual increases or decreases in the number c circulating red cells. Instances of plasma plethor have been reported in secondary anæmias by Keitl Hartwich and May, and others, and extraordinaril low plasma volumes have been noted in polycythæmia The modern dye methods appear to give consister results in normal subjects. Calculated as cubi centimetres of plasma and blood per kilo of body weight, the following average figures have bee obtained in healthy individuals :—

	Plasma. c.cm.	Blood. c.cm.
Keith, Rowntree, and Geraghty (18 cases)[2]	50	85
Bock (5 cases)[1]	51	82
Seyderhelm and Lampe (11 cases)[4] ..	45	82
Berger and Galehr (30 cases)[5]	45	—

The findings in pernicious anæmia are conflictin Keith [6] gives the results of 19 estimates in 12 case In six of these the plasma ranged from 52–63 c.cn per kilo, the blood from 64–82 ; in the remainir cases high plasma volumes were found (66–81 c.cn per kilo) with blood volumes of 77–106 c.cm. H noted that with an increase in red cells and hæmoglobi there was a tendency for the plasma volume to fal Bock,[3] on the other hand, in seven determinations c seven patients, found an average plasma volume (49 c.cm. per kilo, with an average total blood volun of 57 c.cm. per kilo. His lowest plasma volum coincided with the lowest hæmoglobin percentage Rusynak [7] found an increased plasma volume in eigl out of ten patients, the increase bearing no apparer relationship to the corpuscular volume. It seem doubtful whether in this chronic type of anæmia tl circulatory fluid, depleted by loss of red cells, restored to normal by an increase in plasma volum although this is the rule after an acute hæmorrhage

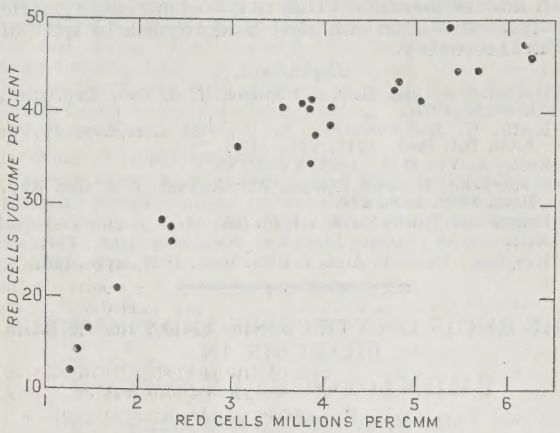
The rapid remission obtainable in pernicio anæmia by treatment with liver affords an unusual favourable opportunity for study of the red cell ar plasma volume. We have employed the vital re method suggested by Rowntree, Keith, and Geraght coagulation being prevented by the addition 1·5 mg. of potassium oxalate per c.cm. of blood. A a matter of interest we have also estimated the plasn protein percentage, the protein being precipitated b the tungstate method of Folin, washed, and i nitrogen content determined by Kjehldahl's metho the resulting figures being multiplied by 6·25. W have also determined the plasma cholesterol conte by the method of Myers and Wardell (see table.)

Comments.

Results of the Liver Diet.—In the eight cases detail in the table and in three further cases in which v made no blood volume determinations the results ha been uniformly satisfactory. The rapidity of t response to treatment has varied, but there w immediate subjective benefit even in one patie whose objective improvement was delayed. T number of cases which we have studied is, howeve small, and in view of the well-known frequency spontaneous remissions and of the fact that none our patients have been under observation for mo

an 11 months we should not be justified in ex-essing any opinion as to the ultimate value of ie treatment. The final red cell counts are higher an those which we have observed by any other ethod of treatment, and the uniform fall in the olour-index may be regarded as a favourable sign. he relationship of cell volume to cell count is shown the accompanying graph, and runs a course similar the colour-index. With the exception of one case l our patients received 6–7 oz. of liver per diem. his patient had been discharged from hospital on senic, but having discovered the value of the liver eatment from a perusal of the daily press he had ken 8 oz. of liver per week at a single meal. On is relatively small allowance his blood presented as tisfactory a picture as any of our more intensively eated patients.

The Plasma and Blood Volumes.—The absolute asma volumes show a considerable degree of nstancy in each patient during the progress of eatment, with a slight tendency to fall during the ter stages of improvement. A definite fall in plasma olume relative to body-weight may occur, but such lls are mainly the reflection of the increase in body-eight which occurs on the liver diet; patients ffering from pernicious anæmia are usually consider-ly below their normal weight when they first come der observation. A considerable gain in weight curred in all our patients with one exception. here appears to be a definite tendency to compensate r the large diminution in the total blood volume, ie to the fall in the red cell volume in this disease, r a corresponding increase in the plasma. The asma volume remains normal. The total quantity circulating fluid is allowed to fall to a low level ring the acuter stages of the malady, and no such tpouring of water from tissues to blood as is seen red cells to a practically constant amount of plasma. The increase in percentage of red cell volume, on centrifuging and in hæmoglobin estimations, gives therefore an accurate index of the actual increase in red cell substance and hæmoglobin during the course of treatment. In drawing deductions from the red cell count allowance has to be made for the well-marked tendency to diminution in the average size of the red cells which accompanies improvement.



Relation of red cell volume to red cell count during treatment.

Plasma Protein and Cholesterol.—The plasma protein findings are of little interest. During the acute stage the plasma protein percentage is slightly subnormal (6·92 per cent. in 19 normal controls). As the patient improves a normal figure is regained. The plasma cholesterol before treatment shows the fall characteristic of pernicious anæmia. A steady increase in this substance occurs during treatment with liver, and in some cases abnormally high values are ultimately attained. The cholesterol rise tends to show a rough parallelism to the increase in red cells, the highest red cell counts usually coinciding with the highest cholesterol figures. This increase in cholesterol is not in any way specific, since it is seen also in other forms of anæmia during improvement. It has been noticed, for instance, in splenic anæmia accompanying the rise in the red cell count that follows splenectomy. Liver itself is said not to be particularly rich in cholesterol, and there seems therefore no reason to

ter acute hæmorrhage occurs in this chronic type of æmia. The relatively slight reduction in the plasma otein percentage confirms the absence of an drræmic plasma plethora.

The plasma volume per kilo of body-weight is proximately normal in the majority of cases. is relationship cannot, however, be regarded as nstituting a very satisfactory standard, since the olume of plasma is unlikely to increase in proportion the adipose tissue, which is relatively poorly scularised. In consonance with this view the fattest tient in our series shows the lowest and the thinnest e highest volume of plasma per kilo of body-weight. mprovement seems to be marked by the addition of

believe that the rise in the plasma cholesterol is the direct result of cholesterol ingestion. Unfortunately, we have had no opportunity of observing the effect of active but cholesterol-free liver extract, since no untreated cases have presented themselves since the extract became available to us.

It may be mentioned that in five of our cases gastric analyses still show complete achlorhydria in spite of clinical recovery.

THE RETICULOCYTE CRISIS AND THE SERUM BILIRUBIN IN PERNICIOUS ANÆMIA.

By S. C. DYKE, D.M. Oxf.,
CONSULTING PATHOLOGIST TO THE WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL;
AND
JOAN GREENER, M.B. Birm.,
FROM THE PATHOLOGICAL DEPARTMENT OF THE HOSPITAL.

THE reticulocyte count constitutes a very important means of ascertaining early whether or not a given case of pernicious anæmia will respond to treatment by liver. A rise in the proportion of reticulocytes to red cells occurs within three days of the commencement of treatment in cases responding satisfactorily. Within a week the reticulocytes should have reached their maximum, which may be over 30 per cent. of the red cells; the number of reticulocytes then falls rapidly and within three weeks from the beginning is approaching normal. An increase is obvious before the increase of the ordinary red cells has become definite. In order to avoid missing the "crisis," counts must be made at the commencement of treatment at intervals of less than three days. The method used in the present instance was that described by Todd,[1] which has the advantage of giving a permanent preparation.

A fall in the serum bilirubin is another early manifestation and would probably indicate response to treatment as well as the reticulocyte count. For this estimation, however, several cubic centimetres of blood are necessary, while for the reticulocyte count enough can be obtained from a needle prick. The sudden and dramatic drop in the bilirubin content of the serum is an obvious indication that one factor in the response to treatment is the cessation of abnormal hæmolysis. The reticulocyte crisis early in treatment is an indication that numerous young red cells are thrown into the circulation as a result of treatment. That the progressive improvement under treatment is not due to the continuation of this inflow is shown by the early drop of the reticulocyte percentage to normal, though the rate of increase of the red cells remains steady. Both the cessation of the hæmolysis and the phenomenon of the reticulocyte "crisis" appear to be capable of explanation on the suggestion put forward by Peabody,[2] who has pointed out that in the relapse stage of pernicious anæmia the bone-marrow is packed with red cells of immature megaloplastic type which appear to be incapable of completing their development. If thrown into the circulation in this state, they are rapidly destroyed. He suggests that the action of the liver is to supply a stimulus enabling these cells to reach maturity. The reticulocyte crisis may be looked upon as representing an act of catharsis on the part of the bone-marrow, after which cell production proceeds in a normal manner.

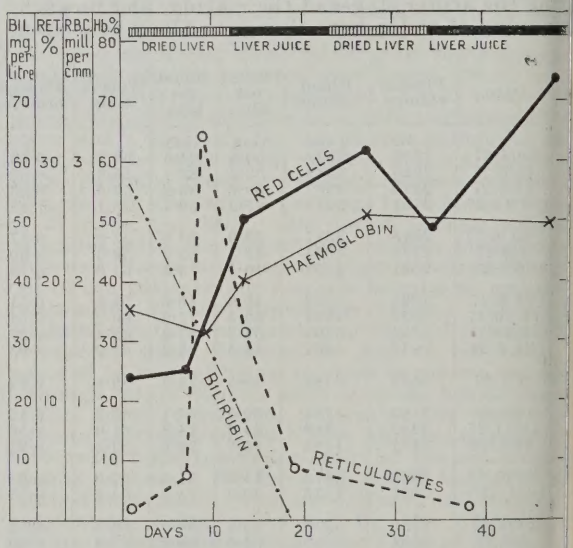
Clinical Details.

CASE 1.—Female, aged 61. The patient herself gave a history of only six weeks' abdominal pain and vomiting her medical practitioner, however, stated that she had been very pale and asthenic for at least three years. On admission on Feb. 18th, 1928, patient showed the characteristic icteric tinge of the skin; her mucous membranes were very pale and she complained of abdominal pain and intermittent vomiting, bearing no relationship to food. Blood picture: hæmoglobin, 35 per cent.; red cells, 1,200,000; colour-index, 1·25; white cells, 2250; polymorphonuclears, 60 per cent.; lymphocytes, 32 per cent.; monocytes, 2 per cent.; reticulocytes, 1·1 per cent. of red cells. Anisocytosis and poikilocytosis present but not marked; no normoblasts or megaloblasts. Icterus index of serum, 36; bilirubin 56 mg. per litre. A fractional test-meal revealed absence of free hydrochloric acid.

The patient was started on a daily dose of 2 oz. of a dried liver preparation (Hepatopson) daily. A week later her clinical condition was unaltered. Blood picture: hæmoglobin, 31 per cent.; red cells, 1,170,000 per c.mm.; colour-index, 1·3; white cells, 5950 per c.mm.; many nucleated red cells; reticulocytes, 32 per cent. of red cells. On March 1st patient was put on 2 oz. of ox-liver juice daily. By this time clinical improvement was apparent. Blood picture on March 3rd: hæmoglobin, 40 per cent.; red cells, 2,480,000 per c.mm.; colour-index, 0·88; white cells, 225 per c.mm.; differential count: polymorphs, 44 per cent. lymphocytes, 49 per cent.; monocytes, 6 per cent.; eosinophils, 1 per cent.; reticulocytes, 15·8 per cent. of red cells.

By March 6th the bilirubin in the serum had fallen to low for estimation. By March 8th the reticulocytes had fallen to 4·3 per cent. of the red cells. The progress of this case from Feb. 18th will be seen in Fig. 1. The reticulocytes fell

FIG. 1.

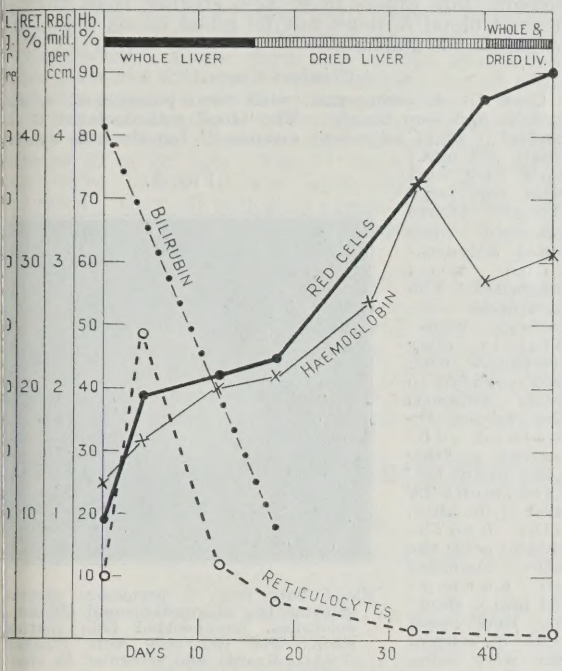


consistently. A drop in both red cells and hæmoglobin between March 16th and 23rd corresponds to a period when the supply of liver juice ran out and the patient was put back upon an insufficient dosage of the dried liver.

CASE 2.—Male, aged 62, complained of increasing weakness for 12 months, breathlessness on exertion, loss of appetite, vomiting, and abdominal pain. He had been treated for gastric ulcer. On admission on Jan. 18th, 1928, he showed a marked icteric tinge of the skin, his mucous membranes were very pale, and he was very asthenic, with numbness and weakness of the legs. Blood picture: hæmoglobin, 25 per cent.; red cells, 970,000 per c.mm.; colour-index, 1·; white cells, 3750 per c.mm.; differential count: polymorphs, 60 per cent.; lymphocytes, 38 per cent.; monocytes, 2 per cent; a good deal of anisocytosis and poikilocytosis of red cells; normoblasts, 1 per cent. of white cells; reticulocytes, 5 per cent. of red cells; icterus index of serum, 17; bilirubin content of serum, 81 mg. per litre. Treatment was initiated on Jan. 21st by the administration of 8 oz. of whole liver daily, according to the diet given below. A fractional test-meal revealed complete absence of free hydrochloric acid.

By Jan. 25th, only four days later, the clinical condition owed marked improvement. Blood picture: hæmoglobin, per cent.; red cells, 1,840,000 per c.mm.; colour-index, 88; white cells, 7000 per c.mm.; reticulocytes, 24·1 per nt. of red cells. Feb. 2nd: Blood picture: hæmoglobin,

FIG. 2.



per cent.; red cells, 2,070,000 per c.mm.; colour-index, 0. Feb. 5th: Reticulocytes, 6·4 per cent.

On Feb. 6th patient was put on 2 oz. of dried liver (Hepapson) daily. On Feb. 8th, blood picture: hæmoglobin per cent.; red cells, 2,360,000 per c.mm.; colour-index, 91; white cells, 6050; differential count: polymorphs, per cent.; lymphocytes, 22 per cent.; monocytes, 7 r cent.; eosinophils, 2 per cent.; icterus index of serum, ; bilirubin content of serum, 18 mg. per litre; reticulotes, 2·8 per cent. of red cells. The progress of the case seen in Fig. 2.

Progress was maintained until the patient left hospital March 1st. One week later the hæmoglobin had fallen om 72 to 62 per cent., while the red cells remained almost ationary at about 4,500,000 per c.mm. The patient was und to be taking an insufficient dose of the dried liver; increasing the dose progress was continued as shown the chart.

LIVER FEEDING IN MULTIPLE INFECTIVE ARTHRITIS.

BY VINCENT COATES, *M.C.*, M.D. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH;
AND
J. L. DELICATI, L.M.S.S.A. LOND.,
RESIDENT MEDICAL OFFICER OF THE HOSPITAL.

AT the present time data in respect of liver in the eatment of secondary anæmia are somewhat scanty. e have therefore studied the effect of liver feeding infective arthritis in which moderately severe to vere secondary anæmia is an almost constant ature.

The cases chosen fall into two clinical groups:) those in which joint lesions are gross, and (*b*) those which they are less defined. Sixteen cases are ported upon (seven men and nine women). The ost severe anæmia gave the following blood estimaon: red blood corpuscles, 2,080,000; hæmoglobin, 8 per cent.; polymorphonuclears, 40 per cent.; lymphocytes, 56 per cent. The least severe showed: R.B.C., 4,832,000; Hb., 74 per cent.; polymorphs, 57 per cent.; lymphocytes, 39 per cent.

No other treatment for anæmia was given before or during the investigation. The amount of fresh liver varied from 5 to 8 oz. daily, according to the individual's ability to ingest this, and it was given for ten days. One patient who was treated with liver tablets had 78 5-gr. tablets in three weeks. The patients on fluid extract of liver took half an ounce twice a day for three weeks. The results were as follows:—

Group A (joint lesions, gross).

1. Six cases in this group had fresh liver with the ordinary hospital diet. Five of them showed marked improvement and one retrogressed. The average results of the five cases of marked improvement were as follows:—

	From	To
Red cells	3,678,000	4,486,000
Hæmoglobin	64·4%	71%
White cells	8,000	10,816
Polymorphs	49·8%	56·2%
Lymphocytes	45·8%	41·4%

2. One case, on liver tablets with ordinary hospital diet, retrogressed.

3. Three cases were treated with fluid extract of liver and given the ordinary hospital diet. Two showed marked improvement and one case remained in statu quo. The average results of the two cases were as follows:—

	From	To
Red cells	4,080,000	4,712,000
Hæmoglobin	64%	80%
White cells	4,480	14,880
Polymorphs	57%	62·5%
Lymphocytes	37·5%	32·5%

Group B (joint lesions less definite).

1. One case had fresh liver and ordinary hospital diet. This case showed marked improvement. The results were:—

	From	To
Red cells	3,960,000	4,496,000
Hæmoglobin	66%	70%
White cells	12,000	6,400

2. Three cases had fluid extract of liver and ordinary hospital diet. Two of them markedly improved and one retrogressed. The average results of the two cases were as follows:—

	From	To
Red cells	4,264,000	5,100,000
Hæmoglobin	74%	69%
White cells	16,480	10,080
Polymorphs	48·5%	62·5%
Lymphocytes	45%	33%

3. Two cases had fluid extract of liver and a Minot-Murphy diet; one showed marked improvement, and one retrogression. The results of the former were:—

	From	To
Red cells	3,232,000	5,072,000
Hæmoglobin	60%	62%
White cells	9,600	10,880
Polymorphs	76%	60%
Lymphocytes	18%	29%

From the small number of cases reported it would appear that certain patients suffering from infective arthritis benefit extraordinarily, in respect of improvement in the blood count, after liver-feeding, whereas others are untouched. A feature of note is that of the 11 cases which improved, seven showed a marked rise in the polymorphonuclear count with a corresponding fall in the lymphocytes, whereas of the four cases which retrogressed three showed the converse.

We wish to thank the laboratory staff of the hospital for their essential help given in this investigation, and Messrs. Armour and Co. for supplying gratis the fluid extract and tablets made by that firm.

DIAGNOSIS OF PERNICIOUS ANÆMIA BY "BLOOD-HALOES."

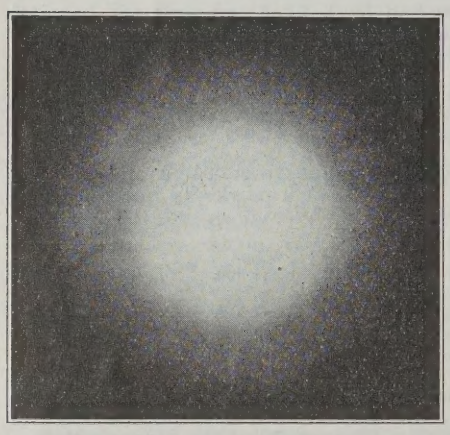
By FRANK C. EVE, M.D. Camb., F.R.C.P. Lond.,
SENIOR CONSULTING PHYSICIAN, ROYAL INFIRMARY, HULL.

THE researches of C. Price-Jones, A. F. Hurst, and others have established that the most constant feature of pernicious anæmia (and often of subacute combined spinal degeneration) is the increase in average diameter of the red cells of the blood. Measurement of 500 cells involves, however, four hours' work with a very costly projection apparatus. Dr. A. Pijper, of Pretoria, recently sent me his paper [1] describing an ingenious method of using a dried blood film as a diffraction "grating." Using a train of three lenses, he conducted the beam of light through a hole in the wall of a dark room. When a blood smear was interposed a "spectrum" was produced, the size of which was inversely proportional to the red cell diameters. I thought the method would be very valuable clinically if it could be simplified. I found that a standardised apparatus, costing £15—i.e., the Thornton-Pickard reflex camera, 1927, F.A., 4·5—answered the purpose admirably. It is also excellent for photographing patients.

Method.

The camera is extended to its full length and brought near enough (2 feet) to focus the filament of a "focus-lamp" (e.g., Osram, 100-watt). The lamp should always be pointed straight at the camera. When a thin blood smear is placed in front of the lens, the image of the lamp is surrounded by two concentric coloured haloes. A home-made celluloid scale shows their diameters in normal blood to be 32 and 65 mm. I measure to the outer edge of the inner halo. In pernicious anæmia, the haloes are smaller (25 to 29 mm.), hazy edged, and usually badly coloured. That is because the red cells are larger and irregular in shape and size so that the resulting haloes and colours overlap. Normal red cells, being round and equal, cause surprisingly efficient "interference" (alternate reinforcement and cancelling) of the light waves.

FIG. 1.



Blood halo of normal diameter (32 mm.) from a cured pernicious anæmia; brightly coloured and sharply edged (natural size). The red cell diameters were also normal (7·2 μ, Knott).

The haloes are easily photographed (10 seconds at F. 16) but are best measured by eye. Blood films of one cell thick are easily secured if the top glass slide is lightly pushed (like a plane) instead of being pulled (as is usual). The slide must first be well rubbed with ether or alcohol. That part of the film which yields the largest halo must always be selected. Fixation is unnecessary, even for posted films. A normal blood film held up to a bright light shows a play of irridescent colours which are not seen in advanced pernicious anæmia. I conclude that the lens coördinates this diffuse irridescence into a halo. Sparrow's blood, with its oval cells, yields neither irridescence nor haloes.

With a large portrait camera I could produce larger haloes, but what I gained in size I lost in sharpness and hence in accuracy of measurement.

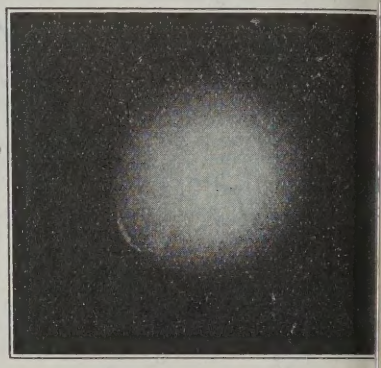
[1] THE LANCET, 1924, ii., 367.

The camera method may show (1) ill-defined and colourless haloes; this means that the red cells are irregular in size or shape. (2) The halo may be sharp and well-coloured but smaller. This is diagnostic of pernicious anæmia or subacute combined degeneration without poikilocytosis. A hazy colourless halo may be given by the poikilocytosis of chronic secondary anæmia, but unless it is also smaller than that of normal blood it must not be relied on as diagnostic of pernicious anæmia.

Clinical Cases.

CASE 1.—A young man with total paraplegia, achlorhydria, and sore tongue. The blood was declared to be normal ("slight secondary anæmia"), but the halo was too small (29 mm.) and the red cells too large (7·9 μ). Hence subacute combined degeneration was diagnosed. The paraplegia recovered completely after treatment with hydrochloric acid, although the haloes remained subnormal. After six months' treatment by liver (½ lb. daily, plus hydrochloric acid) the halo increased to normal (34 mm.), showing that blood cells of normal size were being turned out by the bone-marrow factories. The halo method has given me the same result in four cases of pernicious anæmia after liver diet.

FIG. 2.



Blood halo from a pernicious anæmia showing the diagnostic small (26 mm.) colourless, mossy-edged halo (natural size). The red cells were enlarged (7·55 μ, Knott) and irregular in shape and size.

CASE 2.—A lady of 64 with albuminuria and pyuria of long standing associated with anæmia and large spleen. The diagnosis lay between pernicious anæmia with secondary kidney trouble and primary renal disease with secondary anæmia. A normal halo (33 mm.) decided against pernicious anæmia.

CASE 3.—A lady, aged 65, had subacute cholecystitis with fever and anæmia (Hb. 50 per cent.). The differential diagnosis was cholecystitis with secondary anæmia or pernicious anæmia with cholecystitis due to underlying achlorhydria. The small halo (27 mm.) confirmed by a colour index of 2 settled the matter.

CASE 4.—A man of 53 complained of paræsthesia of hands extremities for six months. He was neither fat nor pale. Hb. 85 per cent. The only diagnostic evidence was pyorrhœa and a blood halo of 25 mm. This suggested a diagnosis of pernicious anæmia with subacute combined degeneration which was confirmed by his sudden death from heart failure [2] and "speckled" heart. Without a quick and easy blood method I should not have diagnosed this case correctly.

Analysis of Halo Diameters of First 55 Cases.

Mouse and hare blood headed the list with haloes of 42 mm. and 37 mm.—their red cells being the smallest. Next at 36 mm. came four infants, aged 2 months to 1½ years. Haloes of 34 mm. were given by the blood of two normal children, a case of Marie's ataxia and one of polycythæmia. Haloes of 33 and 32 mm. diameter were all from normal cases. Two out of five haloes measuring 31 mm. and two measuring 30 mm. were cases of subacute combined degeneration; two more of 30 mm. had pernicious anæmia in the family. The blood of four patients gave haloes measuring 29 mm.; one had pernicious anæmia, another was a child of 2 with grave anæmia, a third had leukæmia, and the fourth was a case of subacute combined degeneration of the cord before treatment with liver. Of the four 28 mm. haloes, three came from cases of pernicious anæmia, one of whom also had subacute combined degeneration; the fourth

[2] Coombs, C. F.: Brit. Med. Jour., 1926, ii., 185.

had bad migraine with achlorhydria, anæmia (70 per cent.), glossitis, and enlarged red cells (8·8 μ measured in 1925 under Dr. A. F. Hurst) and was considered to be on the verge of pernicious anæmia, though without hæmolysis. 27 mm. haloes were given by three cases, two of these pernicious anæmias and one a grave anæmia in a child of 2 cured by liver. The four 26 mm. haloes all came from cases of pernicious anæmia, of whom one also had subacute combined degeneration. There were two 25 mm. haloes both from patients with pernicious anæmia, one of whom had also subacute combined degeneration.

Thus, according to my first 55 cases (confirmed by many later ones), normal adult haloes were nearly always 32 or 33 mm. The 17 haloes of 29 mm. or less were nearly always misty-edged and badly coloured; they all indicated pernicious anæmia with or without subacute combined degeneration of the cord.

Halo Method Checked by Direct Cell Measurements.

Dr. F. A. Knott very kindly lent me four films in which he had measured the red cell diameters.

Film 1 was from a pernicious anæmia patient who had been cured by liver and hydrochloric acid. The red cells were round and equal and of practically normal size (7·2 mm.). Accordingly, the halo was sharp, brightly coloured, and of normal diameter (32 mm.). (Fig. 1.)

Film 2 came from a pernicious anæmia; the cells were very irregular in shape and size and were enlarged (7·55 μ). Consequently the halo was small (26 mm.), colourless, and mossy-edged; pernicious anæmia could be diagnosed at a glance. (Fig. 2.) This case illustrates the important clinical point that an increase of cell diameter of 5 per cent. is magnified into a decrease of halo diameter of 20 per cent.

Films 3 and 4 were from chronic secondary anæmias (hæmoglobin 60 and 50 per cent.) with poikilocytosis. The cell diameters were 7·1 μ and 6·9 μ, and the haloes were pale and hazy, measuring 33 mm. in both films but difficult to measure in (4).

Summary.

The investigation of 60 cases has convinced me that the camera blood-halo method is quick, easy, and reliable, yielding in cases suspected of pernicious anæmia and subacute combined degeneration of the cord decisive clinical information, which is otherwise available only with difficulty and labour.

Clinical and Laboratory Notes.

A NOTE ON SOME INTESTINAL BACTERIA ISOLATED FROM PACKED DATES.

BY R. F. HUNWICKE, B.SC. LOND., A.I.C.,
AND
G. N. GRINLING, F.I.C.

WHEN examining the stools from a severe case of colitis in a young child, we isolated a coliform bacillus having almost the same characters as those given for *B. coli tropicalis* of Cast in Hewlett's "Manual of Bacteriology" (6th ed., p. 428). The distinguishing characteristics of this type are that it is absolutely non-motile, does not ferment dulcite, adonite, or inosite, and ferments sorbite. The non-fermentation of adonite and inosite distinguishes it from *B. lactis aerogenes*, to which it is very similar. The organism was found in practically pure culture in the stools, the only other type found being a short-chain streptococcus, which was not abundant.

It was suggested to us that there might possibly be an association between the presence of this coliform bacillus in the stools and some packed dates which the child had consumed before the onset of the colitis. We were not able to obtain any of the dates from the fancy box which had actually been in use immediately before the attack, but we were supplied with a similar box from the patient's home. The box contained Tunis dates of a well-known brand which had been repacked in France. The dates were examined by cutting off a number of small pieces with a sterile knife and placing them with sterile forceps in tubes of MacConkey's bile-salt broth furnished with Durham tubes. All the tubes on incubation showed abundant production of gas. They were plated to lactose bile-salt agar. At this stage of the inquiry we were only concerned with the possible identification of strains similar to the organism isolated from the stools, and though several intestinal strains were found, preliminary sorting tests showed only one which was obviously similar. The two strains were worked out fully and were found to be very closely related, though not identical.

There seems very little doubt that the severe colitis could be attributed to the organism isolated from the stools. The fact that it was found in the stools in practically pure culture is certainly significant. We have been informed in a private communication that cases of colitis which occurred in the Near East during the European War were attributed to *B. lactis aerogenes*.

The fact that lactose-fermenting, non-sporing bacteria were so readily isolated from the sample of dates seemed worthy of further investigation, and we obtained a number of samples of "block" dates—i.e., dates in bulk—and of packed dates. These were examined by the addition of small fragments to tubes of MacConkey's broth in the manner described above. Tubes which showed production of gas were plated to lactose bile-salt agar and typical pink colonies were picked off, taken into broth, replated, and studied in detail. In examining these further samples we isolated all lactose-fermenting types, as the further inquiry was directed to the possibility of general contamination of dates by intestinal organisms.

We examined 11 samples in all, four being block dates and seven dates repacked in fancy boxes. The block dates were all free from intestinal bacteria, no growth being obtained in MacConkey broth from any sample. From the packed dates a bacillus of intestinal type was isolated in every case except one, in which a lactose-fermenting yeast was present.

The seven strains isolated (including that obtained from the stools) were studied in detail, fermentation tests with 15 sugars and alcohols being carried out in every case. All the organisms were Gram-negative. All fermented lactose with the production of acid and gas, and none liquefied gelatin or blood serum. Litmus milk gave acid and clot in every case. The non-fermentation of adonite and inosite was constant, but marked variations were shown in the fermentation of raffinose. Three strains produced acid and gas from this sugar, two produced acid only, and two showed no fermentation. Four of the strains produced acid and gas from sorbite only after incubation for three or four days. Two strains showed slight motility in 24-hour broth, two were actively motile, and three were absolutely non-motile.

Discussion.

When dates are repacked in Europe a solution of glucose is sprayed over them. This provides a sticky surface to which bacteria would be likely to adhere and which would presumably form a good pabulum for the growth or preservation of fermentative organisms. The block dates, before being sprayed with glucose, present a smooth surface less likely to offer a suitable pabulum to bacteria. It is probable that the dates are handled in the course of packing, and that bacteria are introduced in that process. These observations afford an example of the deceptive appearance of cleanliness which may be conferred on a foodstuff by attractive packing. All the packed dates were attractive and hygienic in appearance, some even being wrapped in transparent wrappings. The block dates appeared dirty and unpleasing to the

eye, yet they proved entirely free from the bacteria with which the packed dates were contaminated.

Whether any danger to public health is involved in the presence of these coliform bacilli on the surface of packed dates is a matter for serious consideration. There is the possibility of specific infection, as in the case of colitis which formed the starting-point of this investigation, and there is also the more general, and perhaps more important, consideration that these intestinal bacteria may indicate fæcal contamination, with the concomitant possibility of epidemic dysentery or typhoid fever. Whether such fæcal contamination occurs, and if so, how, could only be settled by an investigation of packing methods on the spot.

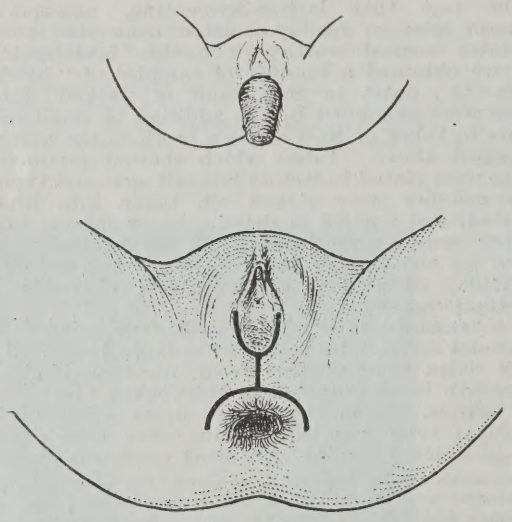
Our thanks are due to Dr. Hector M. Walker (Harrow) for giving us the opportunity of examining the stools from the case of colitis under his care, for obtaining for us most of the samples of dates, and for valuable criticism and advice in interpreting the results of the investigation, which was carried out in the Glaxo Research Laboratories.

NOTE ON AN OPERATION FOR THE CURE OF PROLAPSE OF THE RECTUM IN THE FEMALE.

By Frederick J. McCann, M.D. Edin., F.R.C.S. Eng.

THE failures which I have seen following attempts to cure rectal prolapse in the female prompted me to devise an operation which aimed at the restoration of the retentive mechanism without which the bowel would prolapse with each act of defæcation. The integrity of this retentive mechanism depends on the power and the coördinated action of the levatores ani and sphincter ani muscles, whilst in certain individuals there is a congenital muscular weakness which predisposes to prolapse of the rectum. I have been enabled to observe the results for some years after my operation (in one case 13 years) and so satisfy the *time test*, which is the best test of the efficacy of such operations.

FIG. 1.



The small diagram shows the rectal prolapse. The larger diagram indicates the line of the incision.

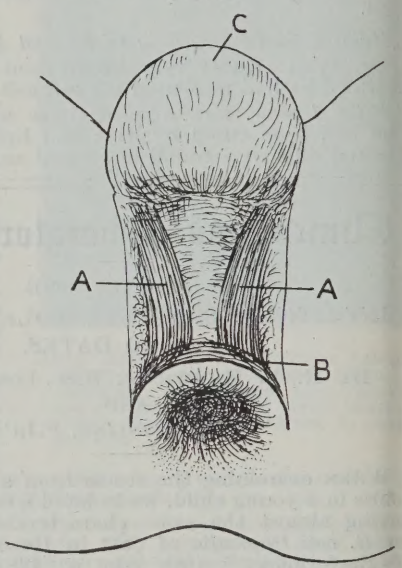
The operation which I perform appears suitable for the majority of the cases.

Preliminary Treatment.—It is essential that the patients should have a preliminary period of rest in bed, not only for purposes of local cleansing, but because congestion is diminished in those who have struggled to be about. The prolapsed bowel should be returned and if possible retained which still further diminishes local congestion.

Description of the Operation.—During the operation the elevated lithotomy position is employed in order to diminish the tendency to protrusion of the rectum.

An incision is made around the dilated anal orifice anteriorly and laterally for three-quarters of its circumference. A mesial incision is then made from the anal orifice to the fourchette which, when deepened, splits the perineal body. This incision is prolonged at its anterior extremity outwards and forwards into each labium (Fig. 1). The anal sphincter and the lower end of the rectum are exposed by dissecting away the superjacent tissues, and the posterior vaginal wall is dissected upwards for about 2 inches (Fig. 2).

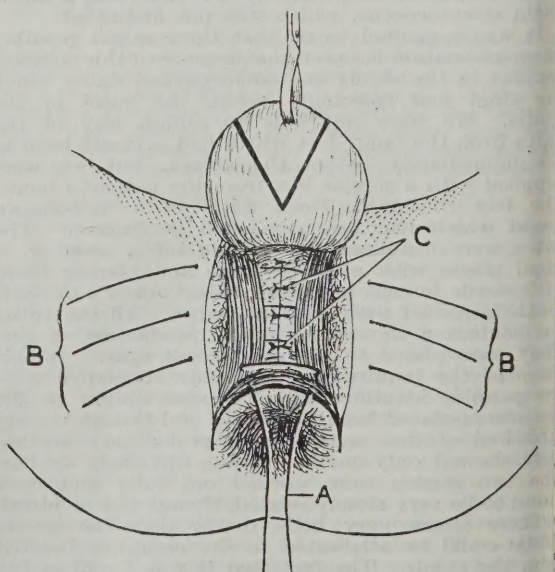
FIG. 2.



C, Vaginal flap. A, A, Levatores ani. B, Sphincter ani.

Catgut sutures are now introduced grasping the sphincter ani, being passed on one side from within outwards under the sphincter muscle and avoiding the mucosa, and in the reverse order on the opposite side and are then tied. A sufficient number of these sutures are introduced to restore the anal orifice to the normal size, and when a good grip of the sphincter muscle is taken by the sutures this muscle is strengthened and tightened and a normal anal aperture is constructed. Sutures of catgut are further used to tighten the stretched or torn fascia over the lower end of the rectum and to reinforce any weak spots. A number of silkworm-gut sutures are next inserted, passing inwards

FIG. 3.



A, First of a series of catgut sutures to tighten the sphincter ani and to restore the anal orifice to a normal size. B, Silkworm-gut sutures. C, Fascial sutures. The V-shaped piece to be excised from the vaginal flap is indicated.

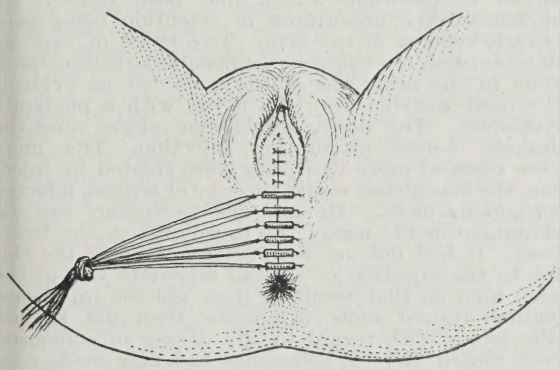
through the skin and levator ani muscle on one side nd outwards through muscle and skin on the opposite ide. The levatores ani muscles are then united by atgut sutures (Fig. 3). A V-shaped piece is excised rom the posterior vaginal wall and the edges united by atgut sutures which when passed also take a grip of the evatores ani muscles in order to bring these muscles and he posterior vaginal wall into close apposition. The skin dges are next united with interrupted catgut sutures and he silkworm-gut sutures tied through small pieces of india-ubber tubing, thus completing the operation (Fig. 4).

The last or most posterior silkworm-gut suture is passed o as to prevent the anal orifice falling backwards, which is ot infrequent after operations for complete rupture of the erineum. Catgut may also be employed for this suture.

A " sacral anus " is a complication which should not e encountered where the necessary precautions have een taken during the operation to restore the anal anal. After this operation I believe it is best to efrain from administering purgatives, at least for ome days in order that healing may remain undis-urbed. Should the patient be uncomfortable in onsequence of the bowel not acting, warm olive oil hould be run into the rectum through a small india-ubber tube and a dose of castor oil given by mouth. he bowels should afterwards be kept acting by a entle laxative.

Although this type of operation remedies the natomical defects which seem to accompany this

FIG. 4.



Operation completed.

ariety of prolapse, yet congenital predisposition is n ætiological factor which cannot be overlooked, or two of my patients were sisters, and I was informed hat another sister and two cousins suffer from rectal prolapse. Exercises to cause contraction of the evatores ani muscles and sphincter ani should herefore be practised after this operation, and uch exercises are still more necessary in the presence f congenital muscular weakness. Finally, this opera-ion offers a prospect of cure, not merely to the urgical derelicts cast adrift because of the failure of ther methods, but to those who bear their suffering ot knowing that anything can be done for their elief, as well as to those who from knowledge of ailures have lost faith in modern surgery.

MANCHESTER PATHOLOGICAL SOCIETY.—At the he annual meeting, held on May 9th, the retiring President, Mr. F. H. Westmacott, vacated the chair, which was taken by Dr. T. A. Goodfellow, President for the forthcoming session. Prof. J. S. Dunkerly gave a demonstration of Venomous and Non-venomous Snakes. Mr. F. H. Westmacott showed specimens and photographs from a case of chronic hypertrophic pulmonary osteo-arthropathy, and Mr. R. D. Mothersole showed a specimen of a congenital buccal cyst about the size of an orange. Prof. Shaw Dunn showed specimens of ulcers of the œsophagus, amongst them two examples of decubitus ulcers of the pharynx, caused by the pressure of the cricoid cartilage against the vertebral column, and Dr. C. Powell White demonstrated a number of microphotographs, illustrating the histology of tumours.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED MEETING OF SECTIONS OF DERMATOLOGY AND SURGERY.

A JOINT meeting of these Sections was held on May 16th to discuss the

TREATMENT OF VARICOSE ULCERS BY INJECTION OF SCLEROSING SOLUTIONS.

Dr. J. M. H. MACLEOD, President of the Section of Dermatology, who took the chair, pointed out that the method was not really new, as 50 years ago a deliberate effort had been made to cure varicose ulcers by injecting perchloride of iron and other substances. They had been given up, however, chiefly because of the danger of causing embolism and severe necrosis, some fatal sequelæ having been recorded. Prof. J. A. Sicard, of Paris, and Prof. G. Nobl, of Vienna, and others had now, however, evolved a treatment which was brilliantly successful with only a minimum of risk and had the great advantage of not interfering with the avocation of the patient.

Prof. SICARD, who spoke also on behalf of his colleagues, Dr. J. Forestier and Dr. L. Gaugier, pointed out that varicose ulceration developed on tissue which had become predisposed thereto by a number of factors. General factors included varix, hereditary predisposition, age, endocrine derangement, and syphilis. The result was a weakening of the vein walls and valves, and also of the supporting perivascular tissues. Mechanical factors might also be operative—e.g., intrapelvic pressure; also much standing, with phlebitis, trauma, or local infections. As regards to treatment, Prof. Sicard submitted the following classification. With post-phlebitic ulcers occurring on an œdematous leg, rest, massage, and support were the reasonable methods of attack. For dirty, serpiginous ulcers of long standing, showing a good deal of local dystrophy, the treatment should consist of rest, disinfection, vaccines, light, and surgery. For ulcers with only a moderate degree of local disturbance—a kind which usually followed a limited dermatitis—local cleansing, as by spirit, should precede sclerosing injections. In cases of mixed syphilitic and varicose ulcerations, antisyphilitic remedies, in association with local obliterative injections, were indicated. Prof. Sicard employed a solution of sodium salicylate, in water, of a strength ranging between 20 and 60 per cent. Both the strength of the solution and the frequency of the injections were determined by the actual condition present. The injection was made into all the veins immediately proximal to the ulcerated area, a dose being 2 or 3 c.cm. Sodium salicylate was preferred, but other substances had been used with the same object, such as quinine, sodium citrate, glucose, and hypertonic saline. When, in early cases, eczema was a prominent feature, that also was improved by the method. He had had no experience of untoward incidents, though a very large number of injections had been made, and he regarded the method as highly efficient.

Mr. T. TWISTINGTON HIGGINS said that Prof. Sicard had first drawn his attention to the method, and that increasing use of it had impressed him increasingly with its value. In the series of cases on which his contribution was based the following solutions had been employed: (1) sodium salicylate, of 20, 30, or 40 per cent. strength; (2) quinine and urethane; and (3) 50 per cent. glucose. The first two of these he had found very satisfactory, but glucose had been disappointing. In an analysis of 200 completed cases it was found that 35 had active ulceration at the time of treatment. Sclerosing injections had been strikingly helpful in promoting the healing of many ulcers, though in some this effect was less

obvious. All his cases of ulcer were also treated with Unna's dressing, ointment, &c. In every varicose ulcer, trophic, traumatic, and infective factors played a part. Some people seemed susceptible to degenerative changes in veins and skin, and when these appeared they were progressive. In the production of an ulcer some trauma could usually be found; it might even be caused by irritation by clothing, or scratching an area of irritation. And when once the skin was eroded, infection easily supervened. The type of ulcer which these injections seemed especially to benefit was that in which the trophic element still preponderated; the common situation for these was over the inner aspect of the lower third of the tibia. Some had gone on for years, in spite of ordinary treatment, but readily yielded to the injections. The case was very different, however, with the infected ulcer; there must be a preliminary cleaning up of the site, with rest in bed, and he delayed injection until surgical cleanliness had been secured. A dirty ulcer might be presumed to carry the possibility of an embolus. Despite the size of the area involved in some of these cases, the injection treatment was of considerable value, though naturally results were less immediate than in uncomplicated cases. He was especially interested in the prevention of these conditions, and injection in his view was most useful in the pre-ulcerative stages, when the danger of ulceration could often be averted. At present only a small section of the numerous patients with varicosity submitted themselves for treatment at an early stage; many tried to carry on with the aid of elastic supports, and came only when ulceration was definitely established. Embolism he regarded as a negligible risk in this treatment. It had not occurred in his own 1232 injections. He always tried to satisfy himself that there was no local or distal focus of sepsis in the patient for here, if anywhere, lay the danger of embolism. He advised his patients to avoid vigorous exercise during the treatment and for three weeks thereafter. There must always be some risk of periphlebitis and local necrosis. His series included 23 cases of periphlebitis, 12 of them going on to necrosis. The risk of this was chiefly in old patients. The general toxic symptoms when they arose he considered unimportant. In one young unmarried woman injection of quinine had caused vicarious menstruation. Following the due reaction, the affected segment of vein was obliterated as a venous channel, hence there could be no recurrence in it. Failure might result either from under-dosage or from too protracted treatment. The worst cases needed many injections, but with care and patience obliteration could almost always be promised.

Sir SIDNEY ALEXANDER, who had used the method since 1925, expressed his preference for salicylate of soda, up to 40 per cent. in distilled water. When quinine was used, patients sometimes complained of pain two or three days after the injection. After injections of sodium salicylate they would sometimes declare they felt better even before leaving the room. It was very important to make sure that the solution got into the vein, and he preferred to make the injection with the patient in the horizontal posture.

Mr. DAVID LEVI summarised the results of 300 cases treated by the method. Five of his patients had had thrombosis at sites other than those injected, three patients had not reacted at all, and in one of them a 66 per cent. solution of glucose, a 25 per cent. solution of salicylate, and lastly, quinine and urethane had all proved unsuccessful. The use of glucose seemed to be followed by more complications than did the other substances.

Dr. W. N. GOLDSMITH alluded to the interference with cutaneous nutrition seen in these cases, with stretching, leading to dermatitis, which was a frequent precursor of varicose ulceration. In all varicose conditions prolonged rest in bed should not be enjoined unless it was accompanied by massage and gymnastic movements; otherwise the patient would not be able to deal with the forces with which he would have to meet on getting up. In only one case had Dr. Goldsmith failed to obliterate veins. Before injection it was necessary to ascertain whether the blood was flowing more rapidly upwards or downwards when the patient was in the upright posture. The only contra-indication to the treatment was a history of phlebitis. Only one injection should be done at a time.

Mr. R. T. PAYNE spoke of 30 cases of venous ulceration which he had treated by this method. Almost all the cases showed healing. He used quinine and urethane, and none of his patients had complained of having tasted the quinine afterwards. In one case vicarious menstruation had ensued. Periphlebitis and local necrosis could be prevented by applying direct local pressure to the site for two minutes after the injection, followed by bandaging.

Dr. H. BECKETT-OVERY said he had given over 500 of these injections, and his experience led him to favour sodium salicylate. He inserted the needle with the patient in the erect posture, and then carried out the injection slowly with the patient reclining.

Dr. ST. G. B. D. GRAY entered into the mechanism of clotting, and said he generally found that a venous ulcer had a feeding vein coming in at the top. The results from sodium salicylate were admittedly excellent, but pain was complained of. He now used quinine and urethane, and had patients in the standing posture for injection.

Dr. FORESTIER summed up the discussion and replied to questions which had been raised. He emphasised the importance of attention being paid to early œdema of the skin. Two types of varicose ulcers existed, one being very amenable to this method while in the other the effects were not so evident. The most suitable were the ulcers with a moderate dystrophy. The dirty, serpiginous ulcers must be cleansed before attempting injection. The more often cases of early varicosity were treated by injection, the fewer cases would there be of serious, infected serpiginous ulcer. He and his co-workers saw no advantage in the use of the tourniquet in the treatment. It had not yet been settled whether the clot due to the injection of sodium salicylate was of the same kind as that resulting from glucose injections. Quinine caused more symptoms than did sodium salicylate. With regard to any danger of embolism Prof. Sicard and his colleagues had now made over 300,000 injections of sodium salicylate, and 25,000 of quinine, without one case of pulmonary embolism. Every patient, however, was given a routine preliminary clinical examination, in respect of abnormalities in the blood pressure, urine, and heart which probably contributed largely to the good results.

On the motion of Mr. V. WARREN LOW (President of the Surgical Section) the openers were cordially thanked for their contributions.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE NEW PSYCHIATRY.

AT a meeting of this Association on May 16th, with Dr. J. HAMILTON MARR, the President, in the chair, Sir JOHN MACPHERSON delivered the Maudsley lecture on the New Psychiatry and the influences forming it.

Psychiatry, he said, was indissolubly linked with the medical and biological sciences and participated in their solidarity and also in their unrest. In addition it underwent vicissitudes peculiar to itself. When Pinel and Tuke had rescued the insane from barbarous ill-usage they had liberated human thought from crude and primitive conceptions of insanity. As a result immense advances had been made in the anatomy, physiology, and pathology of the brain. The advent of psychopathology marked the beginning of the twentieth century and had come unannounced. Janet had demonstrated that hysteria was a mental disorder and could be interpreted in

sychological terms. His contribution to psychiatry as the concept of dissociation, which was the basis the new psychiatry. In some respects his definition as not now satisfactory, for it implied a splitting-up consciousness and of personality, and since the rtical mechanism integrated as a single system it as highly improbable that either could be split. ernard Hart had helpfully described dissociation as n "out of gear" relationship, and had pointed out iat much of the misunderstanding about it had risen from conceiving it as containing a spatial ement. As a working hypothesis this was applicable the whole field of mental and nervous phenomena. ughlings Jackson 50 years ago had described a milar condition, teaching that all morbid nervous henomena were due to a negative factor—loss of nction at a higher level—and a positive factor—ver-function at a lower level. The causes of dissocia-on resolved themselves into two coöperating groups, ie causa causans and the causa sine qua non. To ie latter we could at present only refer as inherent istability of the central nervous system. The iodern return to the study of diathesis, temperament, id constitution might throw light on the subject. was on the cause of dissociation that Freud joined sue with orthodox psychiatry, maintaining that it as the conflict of opposing psychological forces and iat the resulting symptoms were due to an attempt n the part of the organism to adapt itself to altered nditions. Upon this statement he had built a stem of psychology which was more firmly estab-shed than some people believed, for it was unassail-le by direct argument or dialectic attack. Doubt uld not be cast on the observed facts, for they were nown only to the individual psycho-analyst, and iticism of the concepts was met by the legitimate iswer that they were not phenomenal facts, but nceptual formulæ similar to the law of gravity and ie atomic theory. The most serious feature in nctional nervous and mental disorders was the ndency to relapse. Unless the Freudian method uld check this tendency—and there was evidence at it did not do so in all cases—it had no advantages er other methods. The Freudian hypothesis was nbarrassing to psychiatry, but was not supplanting

Psycho-analysis might be described as an *imperium in imperio*. The field of psychiatry was finitely wider than that covered by the Freudian ctrines, and one of its most important departments is the investigation of the physical basis of mental sorder. To say that the brain was a living organ is only to say that it was the material and visible mbol of life. The more elaborate a nervous system, e more perfect were its psychical reactions. It is capable of adjusting the individual to most of the dinary situations of human experience, and operated th in time and space.

The Foundations of an Objective Psychology.

Recent investigations had opened up the possibility at mental processes could be approached objectively the physical plane. The psycho-motor, psycho-nsory, and psycho-inhibitory functions of the cortex re co-extensive and coöperative in the initiation d coördination of formulated expression and rposive action. Disorder of purposive action or raxia resulted from definite organic lesions which parated the psycho-motor function from the psycho-nsory and either from the motor area. Apraxia ght be motor; ideomotor, as in perseveration; or ational. The causative lesions were numerous, and ough were on record to justify the localisation of re motor apraxia in the left frontal lobe and front the corpus callosum and of ideomotor and ideational raxia in the supramarginal and angular gyri and e association area of the temporal lobe. Marie and ead had revolutionised earlier conceptions of hasia. Marie admitted no distinction between tor and sensory aphasia, and denied the existence visual, auditory, or kinæsthetic word-image centres d of storage of word-images in the cortex. He ognised only one centre, diffusely localised in the npero-parietal region, which is specialised for language, and insisted that aphasia was intellectual defect involving general intelligence. Aphasia and agraphia had become symptom complexes produced by the dissociation of definite systems of mental processes, termed by Head symbolic thinking and expression. Temporary or functional forms of apraxia and aphasia had been described by von Monakov, and resulted from a loss of cerebral equilibrium. The cortex functioned by means of vital energy, which kept its various positive and negative activities in uniform equilibrium like the motion of a humming top. This vital neural energy was common to all nervous function, and Head had suggested for it the name "vigilance." Any agency which lowered it disturbed cortical equilibrium and produced dissociation until a new equilibrium gradually became established. Pavlov's remarkable experiments on dogs had demonstrated the existence of cortical inhibition in actual operation. The cortex might be visualised as a mosaic of inhibitory and excitatory areas within which the dynamic activities of irradiation and induction constantly acted and reacted in endless variety. Certain changes in the cortical equilibrium of the dog might result in natural sleep, in a kind of hypnosis, or in acute mental perturbation. Pavlov's experiments had intimated that cortical inhibition and sleep were one and the same process. Excitable and inhibitable types of dogs stood at either end of a temperament- and character-series, and they tended respectively to develop symptoms corresponding to the maniacal and melancholic phases of the manic-depressive syndrome. In predisposed dogs mental disturbances developed as a result either of an unusually acute clashing of excitatory and inhibitory processes or the influence of strong and extraordinary stimuli. The hypnotic symptoms were closely allied to hysteria, and the pathological mental perturbations to phases of circular insanity. Hysteria was a functional form of apraxia in which amnesia, however unobtrusive, was always present. The symptoms were never absolute; sensation was present, though unrealised, in the anæsthetic limb, and contractures relaxed during sleep. These paradoxical phenomena pointed to inhibition of function in the psycho-sensory and psycho-motor centres, with automatic functioning of the corresponding receptor and effector centres of the cortical projection system. As far as it was permissible to compare dogs with men, Pavlov's work indicated that the finely balanced equilibrium of the mosaic of cortical inhibitions and excitations with their dynamic interplay of irradiation and induction was replaced, in the manic-depressive syndrome, by coarser, badly differentiated areas of inhibition or larger, badly inhibited areas of excitation. These researches showed the lines along which mental science was advancing towards the solution of the problem of dissociation. They had broken down the artificial distinction between physiological and psychical processes and reactions and laid the foundation of an objective psychology.

The State and Psychiatry.

The intervention of the State in the care of the insane had been made essential by abuses, but had had certain disadvantages for psychiatry in that it had detailed a much too limited number of medical men for administrative duties and had created an artificial class of certified persons. The prejudice against lunatics and lunacy administration might be discerned in the legislature, the law courts, and the press, and the fundamental error underlying it was that the certified insane alone were mentally disordered. Yet there was no single symptom in the whole range of mental disorders that was not represented in the mental processes of normal men and women, who were only saved from insanity because their more or less efficient cortical mechanisms were able to correct mental refractions and inhibit tendencies to abnormal behaviour. Abnormal behaviour determined the need of certification. The certifying authority ought to be able to go beneath behaviour to the nature and cause of the cortical dissociation, and therefore the statutory appointment of a layman to revise medical opinion

could only be regarded as a device to allay public suspicion. The Lunacy Act of 1890 showed less care for the welfare of the insane than for the protection of the sane. Beyond doubt existing suspicions in the public mind were aggravated rather than allayed by the trend of modern legislation. In countries where there was absence of suggestive "safeguarding enactments" there was little public suspicion.

Napoleon had said: "In the long run the sword will always be conquered by the spirit." The scientific spirit behind psychiatry could not be defined in Acts of Parliament. It tended to evade legal restraints and break through official legislation, sometimes in undesirable directions. The obvious way of guiding it into channels which best subserved the well-being of patients, the growth of scientific knowledge, and the trend of healthy public sentiment was the admission of all cases of mental disorder to public hospitals without certification or judicial intervention. These people should remain under observation and treatment until they recovered or until a liberal period of observation had shown that there was no prospect of early recovery. There was plenty of legal machinery for dealing with the small recalcitrant minority. In conclusion Sir John Macpherson looked forward to the time when methods of physical science would have discovered means for the removal of cortical dissociation more permanent in their results and less dangerous to life than nature's rougher methods, exemplified in the malarial treatment of general paralysis.

A vote of thanks to the lecturer was proposed by Dr. J. G. SOUTAR and seconded by Dr. W. F. MENZIES.

Reviews and Notices of Books.

PHYSICS IN MEDICAL RADIOLOGY.

By SIDNEY RUSS, D.Sc., F.Inst.P., Joel Professor of Physics, Middlesex Hospital; L. H. CLARK, Ph.D., F.Inst.P., Research Assistant, Physics Department of the Hospital; B. D. H. WATTERS, M.Sc., A.Inst.P., Demonstrator to the Department. London: Chapman and Hall, Ltd. 1928. Pp. xii. + 234. 12*s*. 6*d*.

THIS is an excellent book, admirably arranged, which fills a gap in British radiological literature. Of the 17 chapters, the first three deal with electrostatics and current electricity, with electrical conductivity in gases, and with electromagnetic waves. Then follow chapters on cathode and X rays, on the production and properties of X rays, the measurement of X ray intensity, and the wave-lengths of X rays. The phenomena of radio-activity, of radio-active emanations and active deposits, and of dosage in radium therapy form the subject matter of Chapters VIII. to X, while a very interesting section on photography, light, and X rays closes the first part of the book. The remaining chapters (XII. to XVII.) deal with the phenomena of electro-magnetism and with the apparatus used in medical work which depends for its working—primarily at any rate—upon Faraday's discovery. Among such apparatus we may mention motors, high-tension generators, and high-frequency and diathermy currents. There are two valuable appendices, of which the first contains the revised recommendations of the X Ray and Radium Protection Committee (1927); while the second, by Prof. Russ and Mrs. R. H. Somerset, deals with a hospital radium service. Inasmuch as the radon distribution centre of the Medical Research Council is housed at the Middlesex Hospital, and is under the charge of Prof. Russ, it is plain that we have here first-hand information, embodying great experience which will be read with profit by all who are concerned in the use of radium and radon in hospitals and similar institutions.

The authors have succeeded in focusing the main physical facts of special importance in radiological work within small compass. The book mak no claim to be a general text-book of physics, b is an epitome of a particularly specialised branch. modest preface includes a suggestion of regret tha though mathematics are so distasteful to ma doctors, the authors have been unable to refra from introducing mathematical argument into t text where this has seemed essential. No apolo is needed: for radiology without physics is abo as scientific as surgery without anatomy, and so acquaintance with mathematics is essential to ev an elementary knowledge of physics. Those medic men who propose making a special study of radiolo must revise their mathematics, if their use of apparat is to be intelligent, and if they hope to underta any useful research in the course of their practic Prof. Russ himself has been one of the pioneer worke in this country upon the combined physical a biological actions of radiation, and can therefo speak with authority upon the amount of math matical knowledge, which must precede any attem to understand even the elementary principles radiology in its medical applications. One who h had long experience in the teaching and examinati of medical students in physics is not likely to set t standard unduly high. Any effort required grasping the principles set out in the book will well repaid.

DISEASES OF THE LARYNX.

Third edition. By HAROLD BARWELL, F.R.C.S President of the Section of Laryngology, Roy Society of Medicine; Consulting Surgeon, Diseas of the Throat and Ear, St. George's Hospit London: Humphrey Milford, Oxford Universi Press. 1928. Pp. 278. 12*s*. 6*d*.

IN these days of rapid advances in surgical pr cedures and technique it is a difficult task to rev a book after a long interval in such a way that retains the characteristics of its predecessor, and the same time reflects accurately the changes whi have occurred in the interim. Mr. Barwell h succeeded in providing a concise and up-to-da manual for the general physician and surgeon and t student of medicine on diseases of the larynx. T greater part of the book has been re-written. T development of endoscopy has involved not or expansion of the section on examination, but has advanced our knowledge of pathological conditio of the trachea and bronchi as to necessitate t inclusion of much new matter. An entirely n chapter on diseases of the œsophagus has been add Under the non-commital heading, Idiopathic Di tation, is described the condition called, by A. Hurst, achalasia of the cardia, and, by Cheva Jackson, functional hiatal stenosis. The method self-treatment by a rubber bougie filled with mercu which was devised by Hurst, is held by Mr. Barv to be simple, easy, and safe. The chapters Tuberculosis of the Larynx are outstanding, and b the stamp of the author's wide experience in t type of case. His discussion of the treatm indicated is lucid and unbiased, despite the f that he obviously considers that most laryngolog now tend to neglect active local treatment, even cases where it might prove of benefit. In the sect on Malignant Disease he has presented the case and against operation with impartiality, and embodied the most recent results obtained by X r and radium therapy. The practitioner will grateful for the excellent account of the measures be adopted in cases of very advanced laryng tuberculosis and in those of inoperable malign disease of the larynx. Such cases are obvious source of the greatest anxiety to the family doc and most treatises fail to assist him in devi palliative treatment. The printing and illustrat are excellent, and despite the addition of new mate the volume has not been enlarged to an unwie size.

THE LANCET.

LONDON: SATURDAY, MAY 26, 1928.

GLYCOSURIA AND HEREDITY.

THE presence of dextrose in the urine used to be garded as pathognomonic of diabetes mellitus, but years ago a case was described in which glycosuria as associated with nephritis, and the amount of igar in the blood was normal. The next few years w occasional reports of other cases in which the ood-sugar remained at its usual level while dextrose as being excreted by the kidney, and it was soon alised that nephritis was but rarely associated ith this phenomenon, and that, apart from this ding, the patients were perfectly well. The scovery by IVAR BANG that the blood-sugar uld be estimated accurately in small samples, and e subsequent introduction of simpler methods, has ade possible the careful study of many cases of is kind, and it is now clear that the sugar tolerance quite normal. The reason why sugar appears in e urine is that the "threshold" of the kidney is t set at the usual level. Whilst a normal kidney es not begin to excrete dextrose until the blood-gar has risen to 170–180 mg. per cent., the kidneys these patients will do so at lower levels, the thres-ld being set at any point from the normal down to mg. or even lower. The condition may be suspected en glycosuria is found unassociated with any of e usual symptoms of diabetes mellitus, and circum-antial evidence can be got by studying the symp-ms which occur after a drastic reduction of carbo-drates in the diet or after injecting insulin. A finite diagnosis, however, can only be made after serving the effect of a dose of dextrose on the od-sugar, tests being made at half-hourly intervals two hours.

The condition thus discoverable has had various mes, such as renal diabetes, diabetes innocens, and gligible glycosuria. In this country it is usually led renal glycosuria, but the name of orthoglycæmic rcosuria suggested by URBAN HJÄRNE in a recent nograph[1] is perhaps a better, because it signifies at the glycosuria occurs although the blood-sugar normal; furthermore, it does not suggest any ease of the kidney. Almost as soon as the condi-n was recognised it was noticed that it often ected more than one member of the same family, d it is this aspect of the subject that HJÄRNE has n studying. Being lucky enough to find a family which it commonly occurs, he has made exhaustive quiries and observations. Seven generations have n studied, but nothing abnormal was discovered the history of the first three generations, which nprised ten known persons. In the fourth genera-n there were 18 members of the family, and one had glycosuria which did not run the course of a true betes mellitus, and was probably orthoglycæmic. the third generation there had been a marriage between first cousins, and in the fourth generation one of the offspring of this marriage again married a cousin. It is therefore possible to divide members of the next three generations into three groups according to whether they sprang from two, one, or no first-cousin marriages. The group in which there had been no intermarriage consisted of 102 persons, 72 of whom were examined. Of these, ten had either typical orthoglycæmic glycosuria or had had a glycosuria without any symptoms of diabetes mellitus. True diabetes occurred once in the fifth and once in the seventh generation, affording a striking contrast to the other cases. The group which sprang from one marriage between first cousins contained 108 persons, 77 of whom were examined. Fourteen of them had either an orthoglycæmic glycosuria or else a glycosuria without any symptoms. One case of true diabetes developed in the fifth generation and one in the sixth. Lastly, in the third group, which arose from two first-cousin marriages, there were 41 persons, of whom 30 were examined. Of these 2 out of 6 in the fifth, 8 out of 13 in the sixth, and 6 out of 20 in the seventh generation had typical orthoglycæmic glycosuria, as shown by sugar-tolerance tests, and there were no cases of true diabetes mellitus. This careful piece of work shows clearly that intermarriage increases the frequency of this rare abnormality, and after investigating the family records, partly with a view to seeing whether the transmission obeys the dominant or recessive laws of inheritance, HJÄRNE states that "the cases occur entirely in accord with the manner and numbers in which a monofactorial dominant factor is inherited."

For years there has been a difference of opinion in this country between, on the one hand, those who recognised that orthoglycæmic glycosuria was harmless, and did not shorten life, and, on the other, most of the life assurance offices, who took the view that the condition had not been long enough observed for any such conclusion to be drawn. Acting on this opinion they have either refused applicants altogether or loaded the policy against them in various ways. The evidence provided by HJÄRNE confirms the views of previous workers and should go far towards inducing the life assurance offices to alter their attitude towards cases which, on proper investigation, prove to have orthoglycæmic glycosuria.

STATUS LYMPHATICUS.

ABOUT 200 deaths are registered each year in this country as due to "status lymphaticus." We owe the idea that there is an association between unexpected deaths from trivial causes and a bodily constitution characterised by a large thymus and a general excess of lymphoid tissue to PALTAUF, who put it forward nearly 40 years ago, and there is still some doubt whether the expression really means anything more than "G.O.K." In an admirable review of the evidence published last year, Prof. M. GREENWOOD and MISS WOODS [1] came to the conclusion that if "status lymphaticus" exists at all its anatomical signs cannot be recognised post mortem and that therefore it cannot be regarded as a satisfactory explanation of some of the deaths which "would in more pious, but not more superstitious, days have been attributed to the visitation of God." The committee appointed by the Pathological Society of Great Britain and Ireland and the Medical Research Council came to much the same conclusion in their

[1] Jour. Hygiene, 1927, xxvi., 305.

preliminary report.[2] Abroad there has been much discussion and the majority of observers are at least sceptical about the reality of the condition or at any rate about its frequency. It is, therefore, useful to read a survey of the subject by Dr. DAVID MARINE,[3] who takes a different view.

It is generally admitted that a large thymus and big lymphatic glands are found very often in children whose death requires no more explanation than obvious violence, and that infections and malnutrition lead to an extraordinarily rapid wasting of the thymus and lymphoid apparatus; what is commonly regarded as anatomical status lymphaticus is the normal condition of the healthy child and the patients who die of broncho-pneumonia or enteritis after a few days' illness, and from whom most of our experience is derived, have a grossly atrophied lymphoid system. If the children who are run over by motor-cars or killed in fires show the anatomical signs of status lymphaticus, it seems hardly reasonable to look on the same signs as a satisfactory "cause of death" in those who shock the anæsthetist by dying after a whiff of chloroform or who succumb to some experience no more violent than a bath. Dr. MARINE, however, argues that there is more substance in "status lymphaticus" than these facts suggest. Starting with the observations that a large thymus is found pretty regularly in fatal Graves's disease and in a certain number of cases of Addison's disease, and that excision of the adrenals in animals lead to an increase in the size of the thymus, he suggests that there is a group of persons where a primary deficiency or imbalance of the endocrine apparatus leads to lymphoid hyperplasia and a lowered resistance to various stimuli and poisons, and that this group have genuine "status lymphaticus." He deprecates the habit of making the size of the thymus the final diagnostic criterion; different parts of the lymphoid apparatus may be involved in different cases. Other anatomical changes have been described—small suprarenals, hypoplastic aorta, delayed genital development, disturbances in calcification, lymphocytosis, and so on. None of them, however, are at all constantly present, and the best that can be made of the data seems to be the suggestion that it *may* be possible to disentangle from the general mass certified as "status lymphaticus" a small group of cases which are really abnormal anatomically. Perhaps the most likely association is with hypoplastic adrenals; adrenalectomy causes what Dr. MARINE boldly calls "experimental status lymphaticus" and a greatly lowered resistance to various toxins and poisons; the involution of the human adrenal cortex which occurs just after birth may be the explanation of the frequency of "status lymphaticus" in young children. But the case which he makes for the reality of the condition is not convincing.

The problem is difficult to solve, for these unexpected deaths are not nearly as common as their notoriety might suggest, and the controls, in the form of healthy children accidentally killed, are not very common. The recent Coroners' Act seems to have had the unfortunate effect of diminishing the number of examples of sudden and violent death which are subjected to expert examination, and emphasis is laid once more on the grave defect in having no central institute in London where all the medico-legal work should be concentrated in the hands of experienced pathologists, who might have some chance of getting to the bottom of this and similar problems.

THE BRITISH PHARMACOPŒIA.

THE British Pharmacopœia has had to suff many criticisms, and some of them have been d to misconceptions of its purpose and function. T Subcommittee of the Committee of Civil Researc whose recommendations are printed in anoth column, has at least the merit of having made u its collective mind upon these matters. The origin statutory explanation of the Pharmacopœia, w know, is that it is a book containing a list of medicin and compounds and the manner of preparing then together with the true weights and measures b which they are to be prepared and mixed, an containing such other matter and things relatin thereto as the General Medical Council shall thin fit. So said the Medical Act in 1858, and, aft Parliament had declared four years later that t Pharmacopœia of the Council was to supersede th different publications in England, Scotland, an Ireland, the first edition was issued in 1864. Since tha date changes have been plentiful. It was sufficient f the early Pharmacopœias to be descriptive lists medicines compiled by practitioners for use by pract tioners. To-day the British Pharmacopœia mus as the Subcommittee observes, provide not only carefully scrutinised list of current drugs of reput but also authoritative standards whereby the purit and efficacy of these drugs may be tested. To th dispenser it will be an actual manual of practice he must dispense according to its standard an medicament contained in its pages which is mentione in the prescription handed to him. To the physicia it is something different; to him it is not a manu of therapeutics to be consulted in daily practic but a guarantee that, when he prescribes a dr which is mentioned in its pages, he and his patien can be confident that they will obtain an article the quality and character therein defined. T patients mean the public at large, and the publ will be more interested in obtaining the guarant than in the assessment of responsibility and cred amongst those who collaborate in the compilatio

Parliament in 1858 enacted that the General Medic Council should cause the British Pharmacopœia be published under the Council's direction and shou cause it to be altered, amended, and republished often as was deemed necessary. It has been undoubted grievance of many who have labour in this field that the Council—a body created f more than one purpose—had no ad hoc equipme To secure a truly authoritative publication it essential to call the Pharmaceutical Societies in council and to give them the representation whi their services deserve. No better method is lik to be suggested than the proposed new Pharmacopo Commission selected with a reasonable elastic from persons of proved knowledge and experie by a Selection Committee on which all interests w be duly represented. The machinery for revision f the publication is rightly to be made permaner periods of alternative activity and inactivity can cope with the constant correspondence and collat of material which modern conditions dema Revision every ten years, following the United Sta practice, is undoubtedly a sound proposal; suggestion of periodical supplements between successive editions may be difficult to realise, but idea of local supplements to be issued officially India and the other Dominions overseas is proba the only practical method of meeting a kno Imperial difficulty. If India and the Domini can see their way to coöperate in the work, t

an ensure the consideration of their special interests. he finance of the scheme is to have a trial run with a ind of its own. There is apparently a hope that ne General Medical Council will find the proposition elf-supporting.

The Subcommittee, in its report and recommendations, raises many other issues, but it may be sufficient for the present to say that it has discharged ne first duty of such a body by achieving unanimity nd by putting forward proposals in a clear and easonable form.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE GENERAL MEDICAL COUNCIL.

Sir Donald MacAlister was appointed 24 years go President of the General Medical Council. He vas at the time a tried member of the Council, having n 1889 succeeded Sir George Humphry as Representative of the University of Cambridge, but there were many members of the Council senior to him, o that it was significant of the impression which ne had made upon his colleagues that his nomination s their head gave immediate satisfaction to them ll. On Tuesday afternoon last, at the opening of the present session of the Council, Sir Donald MacAlister ttempted to resign this long-held trust, and testified n doing so, to the full measure of continuous support which throughout his extended tenure of office he ad received from his colleagues. For the medical profession we can say that the Council have throughout been well advised in refusing to allow Sir Donald MacAlister to retire from the leadership of their deliberations. From the inception of his Presidency o its close, he has displayed the qualities which all recognise as essential for leadership. He has devoted an ntellect of unusual force and clearness to his far-reaching duties, not sparing himself, yet never unwilling o delegate responsibility or to leave in the hands of others the preliminary and detailed work necessary, f special questions were to be presented in comprehensible form to the general body of the Council. The dignity of his office has been safe in his hands, while he has never lost sight of the fact that the General Medical Council was created by Act of Parliament in the public interest. Medicine and the public already owe Sir Donald MacAlister an unpayable debt, and the news that he has consented to give another term of arduous service is welcome.

FURTHER OBSERVATIONS ON ANÆMIA.

THE papers on anæmia which we publish this week may be regarded as supplementary to those on liver treatment appearing in our issue of April 28th. In reviewing the remarkable results of this remedy in pernicious anæmia, we then pointed out that the work of Whipple and Robscheit-Robbins which led to its adoption was carried out on dogs suffering from experimental secondary anæmia. The natural inference is that liver should have a beneficial effect in human secondary anæmia, though its action in the "primary" variety is evidently much greater, and this inference seems to be justified by the work of Dr. Janet Vaughan at University College Hospital. Two of her cases showed a small but definite increase of reticulocytes, though in others there was no response of this kind. The fact that she could record no benefit in lymphatic leukæmia is not very surprising in view of the wide divergence of the origin of lymphoid cells and red cells, but this negative result should not deter clinicians from trying the remedy in leukæmias of myeloid type. Dr. Vincent Coates and Dr. J. L. Delicati, of the Royal Mineral Water Hospital, Bath, have studied its effect in arthritis of varying severity and record in most cases a rise in the red cell count during the short period of treatment. Dr. S. C. Dyke and Dr. Joan Greener, working at the Wolverhampton and Staffordshire Hospital, have prepared graphs showing that the reticulocyte crisis at the beginning of liver treatment synchronises with a rapid drop of the serum bilirubin to normal. This drop of the serum bilirubin, on the face of it, seems to point to a cessation of hæmolysis, and these observers offer an explanation of the coincidence of the two phenomena based upon the recent American work of Peabody. Conclusive proof is, however, lacking that the increase of the serum bilirubin, almost invariably present in pernicious anæmia, is due to hæmolysis; this is the obvious explanation, but it is possible that the increase is really due to failure on the part of the hæmatopoietic system to make use of the precursors of hæmoglobin. This requires further investigation. Dr. O. L. V. de Wesselow and Dr. Joseph Bamforth, of St. Thomas's Hospital, have been able to confirm the fact that in pernicious as opposed to secondary anæmia the plasma volume is normal and that no variation occurs in the course of treatment by liver. Lastly, we may draw attention to the brief paper by Dr. F. C. Eve, of Hull, who has been studying pernicious anæmia with the technique devised by Dr. Adrianus Pijper, of Pretoria, described in our columns [1] some years ago. Dr. Eve reports a decrease in the size of the red cells after liver feeding in cases of subacute combined sclerosis of the cord. He lays stress upon the importance of this mode of investigation in the diagnosis of pernicious anæmia; but the fact that he was able to demonstrate an increase in the size of the red cells in a child of 2, and also in a patient with leukæmia, suggests that the method should not at present be relied on to the exclusion of other means of diagnosis.

SUNLIGHT AND HEALTH.

A SUPPLEMENT to the issue of the *Times* of Tuesday, May 22nd, forms a valuable summary of our knowledge of the part which sunlight plays in the maintenance and promotion of health in far-reaching directions, and of its direct therapeutic value when artificially applied. The whole of this large reference is well covered in 40 fully illustrated pages; the general lessons in their application alike to natural and artificial sunlight are delivered by recognised authorities, and their value is indicated by careful editorial comment; while the contributions along special lines form a fair and full story of what applied science has been able to effect in many conditions which have hitherto defied our therapeutics. Essays by Mr. T. A. Webster on ergosterol, by Dr. Leonard Hill on the measurement of ultra-violet radiation, and by Prof. Sidney Russ on the electro-magnetic theory of life, will be valuable to medical readers, as they afford the scientific evidence which is relied upon when sunlight therapy, a comparatively new weapon in the practitioners' hands, is employed in particular treatments; the general benefits of balneological methods are exposed in articles by Dr. Fortescue Fox, writing on the British climate and British spas, and by many correspondents from France, Germany, Spain, Italy, Switzerland, Algeria, and Egypt, describing what centres in those countries can offer, special praise being due here to the descriptions by Dr. Kurt Huldschinsky of open-air culture and the practice of actinotherapy in Germany. A large part of the supplement is occupied with descriptions of th influence of access to the sun in improving general environment, and though the teaching may be obvious it is none the less valuable, especially if the information is absorbed by public authorities concerned with the building of schools, the provision of playing-fields, and the organisation of institutional life. The *Times* has done public and timely service in issuing this supplement.

EPHEDRINE IN LEPROSY.

E. Muir and S. P. Chatterji have shown that the nerve pains which form such a distressing feature of advanced leprosy were relieved by the injection of 3–5 minims of 1/1000 adrenalin chloride solution. The benefit resulting from adrenalin suggested that ephedrine, which has the advantage of oral administration, might have the same effect, and in the *Indian Medical Gazette* for April Dr. Muir and his colleague are able to give a satisfactory report of its action. These nerve pains are believed to be caused by the presence of leprosy bacilli in the nerve trunks. In the quiescent stages a proliferation of the connective tissue cells takes place; when febrile reaction takes place the lepra cells are broken up naturally, or as the result of treatment a sudden engorgement of granular tissue occurs, and pressure on the axis cylinders is exerted. Were it not for these nerve reactions leprosy would be a comparatively painless disease, so that a drug which relieves the condition is to be welcomed. Ephedrine sulphate given in hard gelatine capsules in a single dose of 0·05 to 0·1 g. was in most cases sufficient to cause relief in 45 to 60 minutes and its action was maintained for 24 hours, or even longer. Nerve reactions may occur in the course of treatment with iodides, each dose causing pain which lasts from one to three days. If ephedrine is taken whenever the pain commences, the patient is able to continue treatment in comfort until the granulomatous condition is cleared up. The immediate action of ephedrine is attributed to contraction of the arterioles of the nerve trunks and relief of vascular engorgement. It is not yet clear exactly why it fails to relieve a minority of patients. A sequel of its use may be vertigo, and a small preliminary dose is advisable for this reason. Ephedrine has the advantage over opium preparations that the relief of pain is less transient and the effect on the general condition of the patient is beneficial.

ACUTE SYPHILITIC PHLEBITIS.

ACCORDING to Dr. Howard Morrow and Dr. N. N. Epstein,[1] who report a case seen by them in the syphilis clinic of the University of California, phlebitis is one of the unusual manifestations of syphilis, the veins, in striking contrast with the arteries, appearing to enjoy comparative immunity to this disease. Including the first reported cases, described in our own columns[2] by G. P. Girdwood, the writers have collected 45 observations of various forms of syphilitic phlebitis which they have classified into the three groups of early superficial phlebitis, nodular thrombophlebitis, and late phlebitis. Early syphilitic phlebitis, to which they confine their attention, appears as an inflammatory process involving the whole of a superficial vein, several segments of a vein, or a single segment. It has a tendency to be multiple, involving the veins of more than one limb and often progressing from one vein to another. The lower limbs are most frequently attacked, the internal saphenous usually being selected. The phlebitis develops within a few months of the chancre and may accompany or even precede the early secondary rash. As a rule the local and general symptoms are so slight that the condition is readily overlooked, or they may be severe, including nocturnal pains and constitutional disturbance. The skin over the affected area is usually reddened and occasionally there is slight œdema. The limb may be swollen, but does not pit on pressure. Early syphilitic phlebitis has a remarkable tendency to recur either in the original vein or in another in the same or opposite limb. Under specific treatment complete resolution occurs in two or three weeks. Complications are rare, and only one case of embolism has been recorded. The condition is much commoner in the male than in the female, for of 31 cases in which the sex is recorded 27 were in males and only four in females. Strain and alcoholism are supposed to be contributory factors. The chief pathological change is a proliferation of the connective tissue in the subendothelial layer which causes protrusion of the endothelium into the lumen of the vein. The *Spirochæta pallida* has been found in the lesions. According to Morrow and Epstein early syphilitic phlebitis is distinguished from the phlebitis due to other infectious processes by the lack of constitutional and local symptoms, the multiplicity of veins involved, the tendency to recurrence, the rarity of embolism, and the prompt response to specific treatment. In their own case the patient was an alcoholic blacksmith, aged 30, who developed phlebitis in the fourth month of syphilitic infection, the right calf being subsequently involved. Much improvement took place under arsphenamine, but the condition recurred when he resumed work, and a second but milder recurrence developed later. Recovery was eventually complete.

DISCOVERY OF ANOPHELINE BREEDING-PLACES.

IN a malarial area detection of the breeding-places of anopheline vectors may prove difficult, so that pointers to these spots are always welcome. Local variation in splenomegaly was, for example, used with significant effect by the late Dr. S. T. Darling[1] in a Brazilian village five years ago. On a large scale map he marked the homes of all children with enlarged spleens; incidence was far highest near the river on which the village lay, and mosquito larvæ were sought for and found in pools in the low land between village and river. Can a similar use be made of the impression among field workers that male anopheles do not stray so far as females from the water from which they emerged? Is it the case that, in collections of anopheles made from shelters during the day, the percentage of males to females is greater the nearer that shelter lies to the water where they passed their early life? Barber, Komp, and Hayne[2] investigated this matter three years ago. They found that, in over 34,000 specimens of *Anopheles quadrimaculatus* examined, the percentage of males to females was least among those caught in shelters accessible to a source of blood and greatest where no such source was convenient. This is, of course, a distribution such as would occur were males evenly distributed and females congregated close to the sources of the blood meals which they alone enjoy. The actual percentages of males found by these workers were: in animal houses inhabited at night, 6·7; in dwellings, 11·2; in chicken-houses, 17·8; in privies and under dwellings, about 30; in other shelters, 46. It may be that the somewhat greater percentage of females found in animal houses than in dwellings indicates a preference of these female anopheles for animal as against human blood. At all events the investigation leant no weight to the belief that the percentage of males in any shelter had a relationship to its distance from breeding-places. Swellengrebel,[3] investigating this point in the environs of Amsterdam, found that, among some 25,000 *A. maculipennis*, the percentage of males was highest in human habitations and, with the curious and perhaps fortuitous exception of places housing calves, lowest in uninhabited barns and lofts. It has, however, to be added that these last cannot have been far from food sources since 29 per cent. of females caught in them contained blood. More recently Swellengrebel, in collaboration with Rook,[4] has reinvestigated the matter, under the auspices of the Rockefeller Foundation, by the examination on this occasion of over 200,000 *A. maculipennis*. At Medemblik, where the work was done, antilarval measures protect a wide area. At its centre, 3000 metres from breeding-places, males constituted 8 per cent. of captures; at 1600 metres from breeding-places, 16 per cent.; and right among them, 20 per cent. Over these very large numbers, then, a certain relationship can be found between the percentage of

[1] Jour. Amer. Med. Assoc., March 17th, 1923, p. 740.

[4] Rivista di Malariologia, 1928, vii., 7.

ales captured and the distance of the shelter from eeding-grounds. Unfortunately the influence of her factors is so much greater than that of distance at this percentage, whether for *A. maculipennis* or *quadrimaculatus*, cannot, with the relatively small llections usually possible, be used as a signpost to id the hygienist in the field to the breeding-places of ese mosquitoes. Whether this negative conclusion of more general application only wider investigation n show.

ANTISCARLATINAL SERUM AND RELAPSE.

IN an analysis of relapses occurring at Ilford olation Hospital after an attack of scarlet fever ee p. 1060), Dr. A. H. G. Burton and Dr. A. R. almain come to the conclusion that these are more equent in cases treated by antiscarlatinal serum. 1 432 such cases they have found the relapse rate be 4·16 per cent., which is high compared with the nerally accepted rate of from 1 to 2 per cent. It not easy to arrive at an accurate relapse rate of is disease since occasional errors in the original agnosis arise, and many relapses are mild and metimes difficult of recognition. However, the 16 per cent. of relapses in this series of cases can rdly be in doubt since rise of temperature, a nctate erythema, congested fauces, and a peeling ngue were all present. It would be interesting to low whether the relapses were, as is usual, milder an the primary attack, and what relation the verity of the initial attack had to the relapse. They y that antiscarlatinal serum appears to have the finite effect of increasing the number of Dick-sitive reactors during convalescence, and evidence this is given. This is not surprising since the titoxin, being supplied artificially, the need for e human mechanism to set up its defence is less. ey conclude that cases of scarlet fever admitted isolation hospitals should be Dick-tested at the d of the third week, and that it is unjustifiable to tain cases of scarlet fever in a general ward who ve a marked Dick-positive reaction during con-lescence, but that such cases should be isolated or munised. That these conclusions are reasonable n hardly be doubted, especially when antiscarlatinal rum has been administered and so increased the ance of relapses, as shown by the authors. At e present time scarlet fever, being the mild disease at it generally is, the question arises whether it desirable to administer antiscarlatinal serum to cases. There is, however, a tendency towards reased severity to be noticed in certain areas and ew toxic cases have been reported. Doubtless Drs. rton and Balmain had their special investigation view when they gave serum to every case on mission; the opinion held by most observers is at serum treatment may be reserved for the more ere attacks.

RBON MONOXIDE FROM MOTOR EXHAUSTS.

THE rapid increase of motor traffic in all civilised ntries has led to so many mishaps that world-wide ention has been given to the question of the sence of carbon monoxide in the air, not only of ages—where the likelihood of its occurrence is no means as well recognised as it should be—t of the streets themselves. A correspondent the United States of America recently cited [1] some a collected in 14 large cities by officers of the blic health service. Very small, but still deter-nable, amounts of carbon monoxide have been nd in the air of Paris, and the same order of purity has, we are informed, been found in the air London streets by the research chemists of one of London gas companies. The day is probably far tant when the air of our streets is likely to become gerous fron this cause, even if no measures are en to reduce the risk, but a recent occurrence in of the tunnels under the Thames has given minence to the very different atmospheric conditions existing in these sub-aqueous highways now and at the time when they were constructed. The responsible authority appears to be fully alive to the necessity for coping with the problem, not an easy one, of ventilating these tunnels. Everyone will agree that their ventilation should be adapted to modern conditions, but there seems no reason why an attempt should not be made to reduce the amount of carbon monoxide entering the air. This could be done without any public regulation if motorists would make a rule of stopping their engines whenever their cars are brought to a standstill in a confined space. This would seldom mean any real delay as an engine which must of necessity have been running for some time would hardly cool so rapidly as to give difficulty in starting. Motorists as a class are inclined to take risks in this respect which no chemist or medical man would lightly incur. As regards the general question of carbon monoxide in the air of streets, it is consoling to note that MM. Cambier and Marcy discovered no sensible increase in the carbon monoxide content of the air of Paris over the amounts found by A. Gautier in 1877, except when samples were taken at the level of and near the exhaust of a car, or during a traffic block in a one-way street. At the junction of the Place de l'Opéra and rue Auber, as much as 13 parts of CO per 100,000 were found when the number of vehicles passing was 2600 per hour; in rue Mogador, a narrow one-way street, five parts were present during a traffic block. But these amounts represent conditions which are quite transitory.

ANATOMICAL NOMENCLATURE.

AFTER an interval of some years Dr. Cuthbert Morton has renewed his campaign on the present condition of terminology in anatomy. His letter appeared in THE LANCET of May 12th. Concerning the general questions involved in this matter, we see no reason to alter the opinions which we published in 1920, when Dr. Morton had contributed a paper on the subject to our pages. We may say, however, with reference to the item in the agenda of the Anatomical Society to which he refers in his last letter, that we are informed that it was merely a private motion brought by a member at an ordinary meeting, in which he sought for some expression of opinion from his colleagues, and that even then its discussion was, after argument, postponed to a future occasion. Under these circumstances we cannot, of course, say more about it, but it is evident that the facts do not in any way warrant the direful assumptions and forebodings which darken the greater part of Dr. Morton's letter. No one can help feeling sympathy with Dr. Morton in his sorrowful contemplation of the scene of chaos, but, on the other hand, we have a suspicion that the confusion is not so confounding as is often alleged, and that the cry of urgency is perhaps a little overdone. In any case the terminology fated to survive must evolve itself from the materials at hand, and the introduction of another system or set of "principles," although it may add to the material, will certainly not lessen the confusion. Anatomists are as much concerned as anyone with this question, but they seem to be aware of the fact that an international nomenclature is really an impossible ideal. Moreover, as we have pointed out already, their views embrace a wider field than that in which medicine is interested or concerned, and for this reason we would not anticipate much useful result from a conference between them and their clinical brethren. We are in cordial agreement with Dr. Morton's plea for wider use of the English tongue, and we fancy that the competent teachers of anatomy employ their native language much more than might be imagined from a study of many text-books. We must also, like everybody else, admit that the adoption of sound principles of nomenclature would afford a solid foundation for building upon; but as each individual would have his own views on what might be a sound principle, and what could not be so

considered, we fear that the result of an effort to make such a foundation would be far from a success. One is almost tempted to think that the best service to the cause would be rendered by leaving it alone to work out its own salvation by the natural processes of fitness and survival, and to refrain from adding to the number of subjects of dispute.

SERUM TREATMENT OF DIPHTHERIA.

IN an interesting paper on the Control of Diphtheria in Institutions read before the Naval, Military, and Air Force Hygiene Group of the Society of Medical Officers of Health on May 3rd, Surgeon-Commander S. F. Dudley said that to withhold antitoxin until the bacteriological report came was criminal, and that the diphtheria throat swab had been in many ways a curse. These are emphatic statements which it would be well for the profession to ponder over, for there is no doubt that many of the deaths caused by diphtheria are due to the medical attendant awaiting the result of a bacteriological report. Within the past few years attention has repeatedly been drawn to the dangers attending this practice, and there was an annotation in THE LANCET of May 28th, 1921, emphasising this. In the 1928 edition of Goodall and Washbourn's "Infectious Diseases" Dr. E.W. Goodall writes as follows:—

> "Now the writer desires to lay down most emphatically the rule that every endeavour should be made to arrive at a diagnosis before recourse is had to the swab and the culture tube. Many a life has been lost because the medical attendant has waited for the result of a culture or accepted a first finding, negative as regards diphtheria bacilli, as conclusive that the disease was not diphtheria."

Since the annotation referred to was written there has been in London, taking it as a whole, for it appears less evident in certain areas, a slowly growing tendency not to wait for a bacteriological report, and this should receive every encouragement from medical officers of health. Nevertheless it is still regrettably common for diphtheria patients to arrive at the hospitals of the Metropolitan Asylums Board without antitoxin treatment, whose admission has been delayed by the result of the bacteriological examination. It should ever be present in the mind of the medical man how rapidly the danger to life augments in diphtheria if treatment is delayed. It is well to recall MacCombie's figures of some 7000 cases which were adequately treated with antitoxin on admission to hospital. The death-rate of those treated on the first day of the disease was 0·5 per cent.; on the second day, 4 per cent.; on the third day, 10 per cent.; on the fourth day, 15 per cent.; and on the fifth and succeeding days, 16 per cent. Diphtheria is by no means always easy of diagnosis, and it may be difficult to decide upon the attitude to adopt, but if there is doubt the case should be regarded as diphtheria and dealt with as such. Particularly is this so if the condition of the throat shows signs of severity, and it should be a golden rule not to postpone treatment by antitoxin in any acute throat condition which might be diphtheria unless one feels assured that the sufferer will certainly recover. The strong and salutary words of Surgeon-Commander Dudley about the swab recall the statement once made by an authority on diphtheria: "Were it not that the diphtheria bacillus had given us antitoxin it would have been well had it never been discovered." Yet it must be remembered that though the swab is in many ways a curse, because it is so frequently misused, it is nevertheless a valuable addition to diagnosis if used in the proper way to confirm diagnosis, made or suspected by the clinician, after treatment has already commenced.

The fear that unpleasant reactions will follow injection of serum may sometimes influence the decision, and therefore deserves a moment's consideration. To the various accidents which result from the use of antitoxin the term anaphylaxis is sometimes applied, but it is doubtful whether anaphylactic shock ever occurs in man, and in the words of the Medical Research Council's report on diphtheria published in 1923, "serious accidents after inoculation or reinoculation with antitoxins are so rare that no physician ought ever to be driven by the fear of them to withhold antitoxin in any case of diphtheria." This report pointed out that both shock and serum sickness tend to be somewhat more frequent when the individual has had one or more previous injections, and when the antitoxin is given intravenously. When serum is injected into the body an interval of some 12 to 14 days elapses before the subject is rendered supersensitive. How long his supersensitive condition remains is unknown, and sometimes, of course, it does not develop at all. A good rule, however, is that if the patient has previously—more than ten days before—had an injection of serum an attempt at desensitisation should be made. The method usually adopted is as follows: hypodermic injection of 0·5 to 1·0 c.cm. of the therapeutic serum is given, followed by the full curative dose after an interval of five or six hours. Where the practitioner thinks it dangerous to delay for so long he may adopt an alternative method by which a dose of 0·5 to 1·0 c.cm. of the serum is followed ten minutes later by a slightly larger dose, and gradually increasing quantities are given at intervals of about five minutes until the appropriate amount has been injected. In practice it is found that shock is extremely rare whether the person has previously had serum or not.

THE LUNACY LAW OF NEW SOUTH WALES.

THE annual report of the Inspector-General of Mental Hospitals for New South Wales opens this year with an urgent plea for amendment of the State legislation. The changes in the treatment of the mentally sick during the last 30 years have been so far-reaching and rapid that any Act dated 189 must be gravely behind the times. Indeed, this particular one was regarded as out-of-date in 1902 and ever since then the matter has been repeatedly brought to the notice of the Minister, but so far without effect. There is, however, a draft Bill before the Assembly and this, if it becomes law, will provide for persons suffering from mental disease in accordance with the degree of restraint they require. Thus it will be possible to treat patients in the early amenable stages before they need certification. The classification of patients into three groups compares with, although it is not identical with, the grouping recommended by our recent Royal Commission. Those who are amenable to treatment without requiring detention are to be dealt with in ordinary hospitals or special wards. Those whose own interest demand their detention will be kept in special hospitals, while the older mental institutions will continue to receive those who require compulsory detention for their own protection or for that of the public. The property of the first two classes would not be controlled except at the patients' own request, and they would be free to give seven days' notice of their desire to leave the hospital. Laggard as this country may be in some matters respecting mental health legislation, we have a Mental Defective Act and can well understand that the lack of one in New South Wales creates a serious situation. A Bill was prepared some time ago and planned to put under the Education Department defectives of school age and those likely to benefit by instruction, while the older and hopeless cases would be dealt with by the Inspector-General of Mental Hospitals. Other reforms urged in the report as overdue are the establishment of a colony for epileptics and of a committee of psychological experts to examine criminals. In actual practice, however, as Sir John Macpherson pointed out in his Maudsley lecture (p. 1074 of this issue), psychiatry in New South Wales is both advanced and untrammelled. Psychiatric clinics have been established at a number of general hospitals. Medical officers are not appointed permanently until they have secured their diplom

in psychological medicine; a doctor and two nurses are to be sent to America to study occupational therapy, and a system of social service work is under consideration. The Psychiatric Clinic in Sydney, to which Sir John Macpherson was visiting physician, is an example of a modern voluntary hospital which was established without legislative enactment and finds itself happily free from irksome restriction. Voluntary patients are found in all the mental hospitals, but, like our own county asylums, these institutions have no legal right to receive uncertified patients. The new Bill would remedy this anomalous position. The legislature will undoubtedly be making a grave mistake if it does not support its enthusiastic medical staff by the necessary enactments.

HIDEYO NOGUCHI.

WE much regret to learn of the death of Dr. Hideyo Noguchi from yellow fever at Accra on May 21st. Dr. Noguchi went to the West Coast in November of last year to take part in the combined investigation of African yellow fever, in which Prof. Adrian Stokes lost his life last September, and was expecting shortly to return to America. During the last ten years Dr. Noguchi has worked extensively on the disease in Central and South America where his researches culminated in the discovery of a spirochæte to which he attached ætiological importance, which he was able to grow on a large scale in artificial culture and by means of which it was hoped to prepare an efficient vaccine or serum to supplement the sanitary measures which have nearly eradicated the disease in the Americas. The objects of the West African inquiry were to find out whether the disease there was really the same as in Central America (answered already, we believe, in the affirmative), whether it was transmitted by a specific mosquito in the same way, and whether its source was some reservoir of animals from which human infections were derived. The early work of the West African Commission entirely failed to find any signs of a spirochæte and proved as definitely as may be that the disease could be transmitted by an invisible virus by the agency of mosquitoes. It was doubtless a desire to clear up this discrepancy which took Dr. Noguchi to Africa with such unhappy results. His exceptional skill and experience with spirochætes and other parasites will be greatly missed by those who are trying to clear up what remains of the yellow fever problem. Dr. Noguchi was born in Japan in 1876 and educated at Tokyo University. He first went to the United States in 1901 as assistant lecturer on pathology to the University of Pennsylvania. In 1903 he became research assistant at the Carnegie Institute and later joined the staff of the Rockefeller Institute, of which he has become one of the most distinguished members. He will always be remembered for his pioneer work on the cultivation of spirochætes outside the body, for the discovery of the *Spirochæta pallida* in the brain in general paralysis, and in the spinal cord in tabes, and for his researches on yellow fever and on the small-pox virus; the successive volumes of the *Journal of Experimental Medicine* are good enough testimony to his fertile brain and clever hands.

It may be as impossible as it was in the case of Prof. Stokes to find out exactly how Dr. Noguchi took the infection. Possibly it is unwise for any but the young and robust to embark on such inquiries; we recall the deplorable loss of A. W. Bacot from typhus and, on the other hand, remember that Walter Myers died of yellow fever at Para when he was in the 'twenties. The native animals in West Africa have proved entirely refractory to the infection; the discovery that macaque monkeys from India were very susceptible gave the Commission an invaluable method of investigation without which any substantial progress would have been impossible. But it may be that the provision of such a suitable soil has enhanced the virulence of the parasite and made experimental work particularly dangerous—a problem which Dr. Noguchi would have delighted to attack. This second tragedy within a year makes plain the dreadful nature of yellow fever and the fact that even experienced workers are unable to organise investigations in endemic areas without grave risk.

MYOPIA IN JEWISH CHILDREN.

IN a paper entitled Race, Sex, and Environment in the Development of Myopia,[1] Dr. A. Sourasky advances statistical arguments to show that there is no connexion between the development of myopia in children and the time they spend in reading, even reading in an unfavourable hygienic environment; but rather that there is something in the Jewish race which is peculiarly favourable to the development of myopia, and that among children, both Jewish and non-Jewish, the boys are considerably more liable to be affected than the girls. The numbers on which his conclusions are based are not very large —1649 Jewish children and 600 non-Jewish, all in East London—and Dr. Sourasky does not maintain that his thesis is finally proved; but it is not easy, however, to find a flaw in his argument. It appears that the Jewish boys (not the girls) of East London, in addition to attending the ordinary elementary day school, also have classes for the study of Hebrew, lasting 2½–3 hours, on four evenings every week, the lighting and other conditions under which these classes are held being often very bad. The conclusion that suggests itself at first is that the excess of myopia among Jews, and the excess in Jewish boys over Jewish girls, has to do with an excessive amount of study in a bad light. When, however, the ages at which defective vision is found among the Jewish and the non-Jewish children is compared, it is found that the heavy incidence of defect among the Jewish boys is apparent at the very beginning of school life, at the age of 6, and is hardly less then than towards the end of school life. Excessive reading, therefore, so it is argued, cannot have anything to do with the short sight. As far as we know, it has never been suggested that there are peculiar conditions affecting Jewish infants prejudicially more than non-Jewish, which might account for the excess of myopia at the age of 6; this is a point which deserves attention. Dr. Sourasky's figures, however, as far as they go, do illustrate the facts that there are a considerable number of cases of myopia which date from an age prior to the commencement of school life, that their development is largely independent of environment, and that they are especially prevalent in the Jewish race. At the same time the gradual increase of myopia during school life is a well-attested fact, and there is considerable evidence to show that close application to books is one, at any rate, of the factors causing it. In matters of school hygiene to act on any other assumption would be, at present, to say the least of it, premature. In the meantime we hope that others will collect series of cases, for whereas Dr. Sourasky's figures, both for Jews and non-Jews, show a higher proportion of myopes in boys than in girls, collected figures are extant in which no such difference appears.

THE ROYAL SOCIETY'S CONVERSAZIONE.

OF the two conversazioni given annually by the Royal Society at Burlington House, the first was held on the evening of May 17th. Though not, perhaps, so generally attractive as on former occasions, it included many exhibits of medical interest. Dr. R. J. Ludford showed some mice whose ears, tails, noses, and skin had become definitely blue after an injection of trypan blue, and it was demonstrated that while all the normal cells had taken up the pigment, little or none could be found in implanted neoplasms. Any interpretation of this phenomenon must, of course, take into account the fact that the new growths were not spontaneous, but purely experimental. The Pharmaceutical Society showed a

[1] British Journal of Ophthalmology, April, 1928.

collection of mediæval materia medica, including peacock excrement, adder, sharks' and wolves' teeth, millipedes, and mummy. In the absence of modern biological standardisation dishonest traders were apt to substitute recently embalmed bodies for the more mature article. Much attention was attracted by an exhibit, in which Dr. David Keilin, F.R.S., showed that all bacteria, save the anaerobes, yield a pigment which in iron content, chemical structure, and absorption bands, has analogies with hæmoglobin, and which takes part in the respiratory exchange of the organisms. Another effective demonstration, by the British Mosquito Control Institute, Hayling Island, was one in which mosquito larvæ and pupæ were seen dancing in shadow-play on a screen. An exhibit from Kew Gardens of the plant sources of chaulmoogra oil, and an account of their distribution, which is almost entirely confined to the Indian Empire and neighbouring British territories, was a reminder to the profession of the useful work which Kew is doing in their interest. The almost incredible parasitic infection of Scotland's stranded whales, whose guts were nearly blocked with bolbosoma; the excellent preparations of chromosomes in wheat-pollen, demonstrating the aberrations in chromosome content which lead to mutations, and many other exhibits touched upon our professional activities. The exhibition, in fact, gave good grounds for the conceit that the medical career fits a man, better than almost any other, to take an intelligent interest in the multiple activities of science.

THE Sanitary Committee of the City Corporation have recommended the appointment of Dr. W. M. Willoughby, now medical officer of health for the Port of London, as medical officer of health of the City of London.

THE next social evening of the Royal Society of Medicine will be held on Monday, June 4th, at 1, Wimpole-street, W. Sir James Berry (the President) and Lady Berry will receive the guests at 8.30 P.M., and at 9.15 Mr. C. Leonard Woolley will give an illustrated address on Recent Excavations at Ur of the Chaldees.

THE second annual Macalister Lecture of the London Clinical Society will be delivered at the London Temperance Hospital on Thursday, June 7th, at 8.45 P.M., by Sir Berkeley Moynihan, President of the Royal College of Surgeons of England. His subject will be Medicine in Art. The lecture will be open without ticket to members of the medical profession and their friends, but the hon. secretary, Mr. Winsbury White, 51, Harley-street, W. 1, will be glad to receive notice from those who hope to be present.

DONATIONS AND BEQUESTS.—The late Sir William Forwood, of Bromborough Hall, Cheshire, left among other bequests £1200 to the Hospital for Women, Liverpool; £1000 to the Liverpool University; and £250 each to the Royal Infirmary, Liverpool, the David Lewis Northern Hospital, the Royal Liverpool Southern Hospital, and the Stanley Hospital, Liverpool.—The Glasgow Royal Maternity Hospital has received £40,000 for endowment purposes from Mr. A. Walker, of Newart Castle.—Mr. F. B. Sharp, of Cupar, Fife, and his sister, Miss Christina Sharp, have given annuity bonds for £14,000 and £6020 respectively for the further endowment of the new maternity hospital in connexion with the Dundee Royal Infirmary.—Sir Otto Best has given £10,000 towards the £40,000 for which the British Red Cross Society are appealing to establish in London a clinic for the treatment of rheumatic diseases. This gift with other gifts received brings the total amount raised to date to £33,700.—Lord Howard de Walden has given £10,000 to the Mother-Saving Campaign instituted by Queen Charlotte's Hospital, London.—Mr. and Mrs. Richard Dearden Ward, of Sapling Grove, Halifax, on the occasion of the sixtieth anniversary of their wedding, gave £1000 to the Halifax Royal Infirmary.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXVII.

THE TREATMENT OF BRONCHIECTASIS.

FROM the point of view of treatment, bronchiectasis may be classified into two main types: (1) obstructive; (2) non-obstructive.

Obstructive Bronchiectasis.

The causes of obstructive bronchiectasis are foreign body, pressure by tumour or aneurysm, cicatrisation, a malignant or innocent growth in the bronchus. Of these foreign body and an innocent tumour are alone amenable to treatment. Bronchoscopy must be employed whenever there is the slightest possibility of the bronchiectasis being due to obstruction. Evidence of this may be obtained from the history of the case or the employment of lipiodol injections. If either of the above conditions is found it must be dealt with surgically. Even after successful removal treatment on the lines about to be described for non-obstructive bronchiectasis will probably prove necessary.

Non-obstructive Bronchiectasis.

Preventive Measures.—A common cause of bronchiectasis appears to be the after-effects of unresolved broncho-pneumonia. It is, therefore, essential to treat this disease adequately. Long convalescence at the seaside, or some warm dry place in the country, with much rest and later on bathing and sun baths, is indicated. If this regime does not bring about complete resolution diathermy treatment should be tried. A course of vaccines may help. If all these measures fail, a temporary collapse of the affected lung by artificial pneumothorax should be considered, the patient being placed under the healthiest possible conditions of living during the treatment. Sanatoriums for chronic non-tuberculous diseases of the lung are needed.

The Recognition and Management of Established Cases.

Bronchiectatic dilatation may exist with slight symptoms and equivocal physical signs that are in no way pathognomonic. There may be no more than cough, some expectoration and occasional streaks of blood. It is only by the injection of lipiodol and subsequent radiography that the diagnosis in such cases can be made. The general principles of treatment have next to be considered. The essential underlying cause of all types of bronchiectasis, whatever hypothesis may be held of the mechanism of dilatation, is an inflammatory process in the walls of the bronchi. Our first aim is to overcome this inflammation; our second is to close the cavities if necessary and if possible, or to prevent their extension. The following are the methods that may be adopted:—

General Hygienic Treatment.—Prolonged climatic treatment is essential in a warm seaside or country place. Fresh air is important and also rest, especially while the temperature is raised. As in the preventive treatment, bathing and sunbaths may be allowed after a few weeks. If no sun is available ultra-violet rays may be employed. Care must be taken of the teeth, throat, nose, and its accessory sinuses, and any focus of infection therein must be removed. The diet must be full and well balanced.

Diathermy applied to the affected part is well worth trying.

Postural Treatment.—Two or three times a day the patient must lie with the head and shoulders lower

an the rest of the body, the pus will then flow into e larger bronchi, excite a cough reflex and so aid emptying the dilatations. In some cases it is well let the patient lie for some time with the foot of e bed well raised. This treatment must be carried it thoroughly and conscientiously.

Creosote Chamber.—This is an excellent measure the patient is not too ill or debilitated. By pro-king cough the creosote helps to expel the pus. It so tends to render the breath less offensive. Fre-iently a crude creosote chamber can be improvised an outhouse in the patient's garden.

Vaccine Treatment.—I am doubtful of the value vaccine treatment in definite bronchiectasis. I ve seen some alarming reactions and am a little raid of vaccines in this condition. If they are ied it must be with great caution, starting with nall doses and increasing them very gradually.

Medicinal Treatment.—(*a*) *Inhalation:* A few drops the following solution—carbolic, chloroform, eosote, 2 parts, iodine and ether, 1 part, placed in Yeo's inhaler and inhaled for increasing periods time render the breath less offensive and may have antiseptic action. (*b*) *Drugs by mouth:* Creosote capsules may be given by mouth in increasing ses up to minims 20 or 30 three times a day. uaiacol carbonate, ipecacuanha, oil of sandalwood, rpentine, garlic, or arsenic may be tried. (*c*) *Intra-acheal injections:* Many substances have been jected into the trachea, such as preparations of enthol or menthol and guaiacol in oil. More cently gomenolised oil, 1 to 5 per cent., and lipiodol ve been used in this way, but their value is uncer-in. In many patients it is a very easy matter to ject 5 to 20 c.cm. of lipiodol into the lung by the oral ethod. The patient sits on a chair with the tongue otruded and held while the oil is slowly injected er the back of the tongue, the patient being couraged to breathe deeply and to relax. In a lerant subject the whole of the injection will flow once into the right or left lower lobe as desired thout the least difficulty. No cocainisation is cessary. Other oily preparations can be injected the same way. In my opinion a further trial of ese methods should be made.

Collapse Methods.—If the above methods fail me form of collapse therapy will be indicated. e simplest of these is artificial pneumothorax. this is successful and produces the desired result e problem will usually arise how to make the collapse rmanent. In certain cases, especially in children, seems that a temporary collapse will cause a great provement and appear to arrest the progress of e condition. Several such results have been reported m different parts of the world and I have observed e same thing in my own clinic. This was before e days of lipiodol, however, and it is a matter of mmon knowledge that to differentiate between imple fibrosis and slight bronchiectasis is impossible thout the use of lipiodol. Nevertheless, it is not ficult to understand how a temporary collapse ay tend to cure even in definite early bronchiectasis, the bronchi will be relieved of strain and stresses ile the subacute inflammatory process subsides. a rule, however, a temporary collapse will be sufficient. A life-long pneumothorax is impracti-ble even if it were possible, and unfortunately bronchiectatic dilatations the walls of the cavities ll not adhere as they do in tuberculosis after mpression. There are two possibilities: (*a*) con-rting the pneumothorax into an oleothorax; (*b*) lapse operations.

By *oleothorax* is meant oil in the pleural cavity. e oil that has been most commonly employed is ve oil containing 5 per cent. of gomenol. This ll remain unabsorbed for at least six months and lls are therefore needed only at long intervals. e oil remains sweet and apparently unaltered. e discomfort to the patient is surprisingly small. e of my patients, with his left pleural cavity completely filled with oil, has been doing full work for over two years and he complains of no discomfort.

Collapse Operations.—If the disease is basal and the methods described above have not proved successful *phrenic evulsion* should be first considered. It is a simple procedure, has been performed probably thousands of times, and there have been few compli-cations. If it does not cure the disease no harm has been done, as it is an excellent preliminary to pro-cedures about to be described. If the disease is not basal but definitely localised in some other part of the lung, *pneumolysis* is the operation of choice. It involves little or no shock and no mutilation. Per-formed as it may be from an axillary approach, no visible scar results. The objection to this otherwise ideal procedure is that no really satisfactory packing substance is known. Paraffin and fat are most commonly employed, but both are apt to be extruded little by little through a pin-hole sinus. If this fails, or if the disease is widespread, *thoracoplasty* must be considered. This, however, is a big and a mutilating operation and demands very careful consideration before it is embarked upon. Never-theless, in suitable cases and performed skilfully, the operation gives the patient what is probably, at the present time, the greatest chance of complete and permanent recovery. The collapse to be successful must be very thorough. It may be necessary after the complete paravertebral operation to resect ribs anteriorly as well. Amyloid disease, a toxæmic or degenerative condition of the myo-cardium, pyæmic abscesses in other parts must be carefully excluded, before such operative procedures are advised. *Rib mobilisation* used to be performed before thoracoplasty achieved its present popularity, and I can recall one case particularly where a striking cure was obtained by this method.

Removal of the Diseased Area.—Attempts have been made to remove the affected lobe by simple lobectomy or cautery lobectomy. This method is still in a tentative and experimental stage; theoretically it is an ideal process for the purpose, and when the technique improves and the operation becomes safer it will probably be employed extensively.

Drainage of a Large Bronchiectatic Cavity.—When the symptoms appear to be due chiefly to a very large single cavity, drainage may be attempted. This may relieve some of the most distressing features, dimin-ishing very considerably the amount of pus expec-torated. For this operation it is essential for the two layers of the pleura to be firmly adherent, as in drainage of a pulmonary abscess. A rib is resected, the ribs above and below are retracted, and the parietal pleura is carefully exposed, any injury to it being avoided. If not adherent the parietal layer of the pleura can usually be seen moving upon the visceral layer, or it can be lifted up with blunt forceps. If it is found free, the external surface of the parietal pleura is painted with iodine and packed with iodine or iodoform gauze, and the wound is lightly stitched up. After four to seven days the two layers of pleura will be found adherent. The lung may then be incised and the cavity drained.

Advanced Bilateral Disease.—If the disease is well established on both sides, none of the collapse methods will avail. All that can be done is to employ the other measures outlined above. If one side has advanced disease and the other side is but slightly affected, it will be a matter of judgment whether it is better to employ some form of collapse therapy on the worse side in the hope of arresting the further extension of the disease. Prolonged medical and climatic treatment must in any case follow. In bilateral disease, however, operative procedures must not be undertaken lightly.

THE BRITISH PHARMACOPŒIA.

REPORT OF SUBCOMMITTEE.

THE existing law as to the preparation and publication of the British Pharmacopœia is confined to a single section of the Medical Act of 1858 and two sections of the Medical Act of 1862. The effect of this legislation is to impose upon the General Medical Council the duty of causing a British Pharmacopœia to be published under their direction, and of causing it to be altered, amended, and republished as often as they think proper.

In July, 1926, a subcommittee of the Committee of Civil Research was appointed with the object of ascertaining whether it is desirable to make any alteration in the law or practice relating to the preparation of the British Pharmacopœia and to its adaptation to the requirements of the British Empire.

The personnel of the subcommittee was as follows: Mr. H. P. Macmillan, K.C. (chairman), Lord Dawson, Sir Donald MacAlister, Dr. H. H. Dale, F.R.S., Mr. Edmund White, F.I.C., Dr. H. G. Dain, and Mr. A. F. Hemming. Their report has now been issued. It consists of an introductory section describing the procedure adopted, an historical survey of the pharmacopœia in this country, before and after the Medical Acts, and an account of the financial arrangements governing its production. Criticisms of the present system are dealt with and the proposals of the subcommittee set out. The adaptation of the British Pharmacopœia to the requirements of the British Empire are then discussed, and the report ends with the following summary of the principal conclusions and recommendations arrived at:—

1. That it is not necessary or desirable to make any alterations in the existing law relating to the preparation or publication of the British Pharmacopœia, but that the practice in the matter be altered in conformity with the recommendations which follow.

2. That the General Medical Council set up forthwith a Selection Committee to be charged with the duty of selecting persons to form a new body to be designated "The Pharmacopœia Commission."

3. That the composition and functions of the Selection Committee be as follows:—

(*a*) The Selection Committee should consist of four persons nominated by the General Medical Council, three persons nominated jointly by the Council of the Pharmaceutical Society of Great Britain, the Council of the Pharmaceutical Society of Ireland, and the Council of the Pharmaceutical Society of Northern Ireland, and two persons nominated by the Medical Research Council; the representatives in each case to be chosen by the nominating body either from among or from outside its membership.

(*b*) The Chairman of the Selection Committee should be appointed by the General Medical Council from among their four representatives.

(*c*) The Selection Committee so appointed should select persons representative of the various appropriate departments of knowledge and experience to form the Pharmacopœia Commission.

(*d*) The number of persons selected to form the Pharmacopœia Commission should not be prescribed, but should be left to the discretion of the Selection Committee, who should have power from time to time to select additional persons for permanent or temporary membership, including representatives of India or the Dominions.

(*e*) The Selection Committee should submit to the General Medical Council for approval the name of one of the selected persons to be Chairman of the Commission.

4. That the manner of appointment, composition, and functions of the Pharmacopœia Commission should be as follows:—

(*a*) The Pharmacopœia Commission should be appointed by the General Medical Council, its members being persons whose names are submitted to the Council by the Selection Committee.

(*b*) The Pharmacopœia Commission should be a permanent body with an office and suitable secretariat, and the work of collecting and collating material, preparing reports and conducting correspondence with a view to the preparation of future issues of the Pharmacopœia should be carried on continuously.

(*c*) The actual work of preparing future issues of the British Pharmacopœia should be undertaken by the Pharmacopœia Commission under the general direction of the General Medical Council; on each revision the completed volume should be submitted by the Commission to the General Medical Council for approval and when approved it should be issued as heretofore with the authority of the General Medical Council.

(*d*) The Pharmacopœia Commission should have power to appoint subcommittees, and to include among the members of such subcommittees experts in any particular branch, whose assistance may be desired, although they may not be members of the Commission.

5. That in future the British Pharmacopœia should—

(*a*) Be revised and reissued at stated intervals of ten years, supplements being issued between the successive editions as required.

(*b*) Contain only standard drugs in general use throughout the Empire.

6. That where it is desired in any part of the Empire to sanction the use of particular local drugs, or alternative preparations not included in the British Pharmacopœia, they should be left to be effected by the Governments concerned by the issue of local supplements or addenda.

7. That the Governments of the Dominions and of India be requested by the General Medical Council, through the appropriate channels, to set up or cause to be set up responsible and representative committees to coöperate with the Pharmacopœia Commission in the revision of the British Pharmacopœia, if they desire and are willing to take part in the work.

8. That at any rate until the results of the publication of the next revision are seen, the funds necessary for carrying on the work of the Pharmacopœia Commission be provided by the General Medical Council, who should receive the proceeds of all sales of the Pharmacopœia, a separate account being kept.

The subcommittee, in presenting these conclusions and recommendations, ask that they shall be considered in the light of the more detailed exposition of their views embodied in the report (Cmd. 3101, 1s.) which can be obtained from H.M. Stationery Office. The report is signed by all the members of the subcommittee.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the General Council of King Edward's Hospital Fund for London was held at St. James's Palace on May 15th when the Prince of Wales, who presided, read the following message from the King:—

"The King is glad to hear of the results achieved by the special distribution of the sum of £255,000 received from the estates of the late Mr. and Mrs. John Wells, which has helped the hospitals of London to provide 1600 additional beds and to meet other urgent requirements. His Majesty regards this as a striking proof of what can be done by a Central Fund, when it is in a position to make grants to hospitals which especially need financial assistance, and where the utmost use will be made of the help thus given."

In addressing the meeting the Prince of Wales said that the accounts showed, not for the first time, a better result than was anticipated in November. Since the end of the year the capital had been increased by a very generous donation of £10,000 from Mr. J. J. Crosfield, with a request that it should be invested. When Mr. H. W. Marshall gave £10,000 Conversion Stock last year, in connexion with the thirtieth anniversary, he asked that it should form a separate fund to be called the Marshall Fund, to which members of his family might, if they so desire, add further sums. A bequest by a member of Mr. Marshall's family had since been added to the fund thus created. The inquiry by the Pay Beds Committee into the question of hospital accommodation for the middle and professional classes was nearly finished, and the report was being prepared. The conclusions, whatever they may be, would

based on a study of pay beds as they now existed at a number of hospitals in London. The statistical report showed that in 1926 there were nearly 900 pay beds at 73 hospitals. Any suggestions the Pay Beds Committee might make for the future would thus be based on the experiments, if he might so call them, of the past and the present. The final list of grants out of the legacies of the late Mr. and Mrs. John Wells was the end of a most useful piece of work which began in 1924. The last instalment of the two legacies had just been received, and the combined total had come to £255,000. His Royal Highness concluded by referring to the loss to the Fund by the death of Lord Cave, Sir William Church, and Sir John Craggs. In the place of Sir Francis Champneys, who had retired after 17 years' good service, he (the Prince) had appointed Mr. Eardley Holland; Lord Iveagh he had appointed as a member of the Council.

The Finances of 1927.

Lord Revelstoke (the hon. treasurer) then moved the adoption of the accounts for 1927, which was seconded by the Rt. Hon. M. C. Norman, and carried unanimously. The Earl of Donoughmore (chairman of the Management Committee) proposed the adoption of the annual report, and this having been seconded by Sir Berkeley Moynihan (President of the Royal College of Surgeons), was also carried unanimously. The report stated that the total receipts of the King's Fund for the year 1927 were £352,340 18*s.* 9*d.* Of this, £22,000 was from the estate of the late Mrs. John Wells, £1313 0*s.* 8*d.* from the estate of the late Mrs. Florence Mary Hames, £1000 from the estate of the late Mr. Samuel Lewis, £15,004 15*s.* 10*d.* from general legacies, £67,638 4*s.* 3*d.* from gifts to capital (including £60,000 from the estate of the late Earl of Iveagh), and £245,382 0*s.* 5*d.* from general receipts. These general receipts were made up as follows: Annual subscriptions, £23,432 15*s.* 2*d.*; donations, £20,789 16*s.*; League of Mercy, £17,000; British Charities Association, £15,000; dividends and nterest from investments, £168,959 9*s.* 3*d.*; and trustees of the Bawden Fund, £200. The amount of the ordinary distribution was £247,000, an increase of £2000 over 1926. The total sum distributed amongst hospitals, convalescent homes, and consumption sanatoriums during the last ten years, including all special distributions, is £3,360,688. Since the foundation of the Fund in 1897 a total net amount of £5,819,104 8*s.* 5*d.* has been distributed.

Grants under the Wells Legacies.

Sir Cooper Perry (chairman of the Distribution Committee) presented the final report on the Wells legacies distribution which contained the following list of grants made from Jan. 1st to May 15th:—

Acton Hospital: £1000 towards revised scheme of extension, increasing the number of beds from 50 to 60; £500 payable when the work is begun, and £500 to be the last £500 required to render the scheme free of debt.

British Hospital for Mothers and Babies: £500 towards second stage of new hospital; making, with £2000 granted in 1927, a total of £2500.

Central London Throat, Nose and Ear Hospital: £750 towards new out-patient department; on condition that a further £5000 is raised and the work begun by July 31st, 1928.

Charing Cross Hospital: £2000 towards reconstruction and equipment of the building acquired from the Royal Westminster Ophthalmic Hospital, increasing the beds by approximately 50; on the understanding that 6 additional beds, making 10 in all, will be reserved for accident cases.

Elizabeth Garrett Anderson Hospital: £500 towards extension; making, with £2000 granted in 1926, a total of £2500.

Forest Hospital: £250 towards extension, increasing the number of beds from 28 to 37; payable when the work is begun.

General Lying-in Hospital: £500 towards rebuilding of adjoining house as nurses' home and antenatal and postnatal departments; making, with £1000 granted in 1927, a total of £1500.

Guy's Hospital: £1000 towards provision of site for out-patient department extension.

Hampstead Hospital: £600 towards new operating theatre and casualty department and provision of 6 accident beds.

Hornsey Central Hospital: £500 towards new nurses' home; payable when the work is begun.

Hospital for Sick Children: £500 towards provision of isolation block for convalescent patients at the country branch at Tadworth, on the understanding that the block will ultimately be used as part of the provision for recovery patients.

King George Hospital: £10,000 towards the building fund of King George Hospital, subject to conditions to be agreed.

Mothers' Hospital of the Salvation Army: £1000 to extension, increasing the number of beds from 90 to 150, payable when the work is begun.

Prince of Wales Hospital: £3000 towards extension of out-patient department; £1500 payable when work is begun, and £1500 to be the last £1500 required to open the extension free of debt.

Princess Louise Kensington Hospital for Children: £500 towards second stage of new hospital; making, with £500 granted towards first stage in 1925, and £1000 towards second stage in 1927, a total of £2000.

Queen Charlotte's Maternity Hospital: £3000 towards first stage of extension scheme, increasing the number of beds; payable when a further £15,000 has been raised and the work begun.

Queen's Hospital for Children: £1000 towards extension, increasing the number of beds from 134 to 155, and providing additional nurses' accommodation; to be the last £1000 required to enable all three parts of the scheme to be opened free of debt.

Royal London Ophthalmic Hospital: £500 towards additional nurses' accommodation; making, with £500 granted in 1926, a total of £1000.

Royal National Orthopædic Hospital: £1500, of which £500 towards acquisition of adjoining site at country branch at Stanmore; and £1000 towards building of additional ward block at Stanmore, increasing the number of beds to 273; payable when the work is begun.

Royal Waterloo Hospital for Children and Women: £250 towards final stage of extension scheme; making, with £3000 granted in 1925, a total of £3250.

St. Mary's Hospital: £1000 towards extension; to be the last £1000 required to render the extension free of debt; making, with £4000 granted in 1926, a total of £5000.

South London Hospital for Women: £500 towards the provision of block containing new out-patient department and nurses' quarters; making, with £2000 granted in 1926, a total of £2500.

Westminster Hospital: £100 towards provision of accident ward, increasing the number of beds in the hospital from 234 to 242, of which 10 will be reserved for accident cases.

Woodford Jubilee Hospital: £300 towards extension, increasing the number of beds from 23 to 31; payable when the work is begun.

Reports were also presented on the work of the Propaganda Subcommittee by Lord Burnham; on the new edition of the Statistical Report by Mr. L. L. Cohen; and on the position of the inquiry by the Pay Beds Committee (to which reference was made in the Prince's opening speech) by the Earl of Donoughmore. During the absence of Lord Hambleden through illness, Sir John Rose Bradford is acting as vice-chairman of this committee.

A vote of thanks to his Royal Highness terminated the proceedings.

MEDICINE AND THE LAW.

Death Certification by Unregistered Doctor.

Charles Forbes, aged 77, pleaded guilty at the Old Bailey on May 18th to a charge of forging and uttering a death certificate. The certificate, as was stated a month earlier at Clerkenwell Police-court, related to one Mary Wagner and purported to be signed by Charles Forbes, M.B., Ch.B., a registered medical practitioner. A second charge in the police-court proceedings alleged that he had knowingly and unlawfully caused to be inserted in the register of deaths kept for the subdistrict of South St. Pancras a false entry relating to Mary Wagner's death. There was evidence that Forbes had been living for about seven years at a private hotel and, posing as a registered medical practitioner (though he had not put up a brass plate), had treated many poor people in the West Central district of London. For the defence it was stated that Forbes had duly qualified as a doctor at Glasgow after being a student at the

Middlesex Hospital, and that he had been struck off the Register about 30 years ago after a conviction for fraud. The Recorder remarked that he was of opinion that Forbes had never been a doctor at all; he was a danger to society. Sir Ernest Wild then passed sentence of nine months imprisonment without hard labour. It seems that the accused, in treating Mary Wagner, who was dying, had been obliged to pose to her nephew as a registered medical practitioner who could sign a death certificate. The unregistered practitioner must sooner or later be exposed to the risk of thus being led into a definitely illegal act, though the general public naturally takes little interest in the certification of qualifications or the fact of registration. As Forbes was not in fact registered, his previous career was not directly in issue; otherwise it would have been interesting to know whether he had in fact ever obtained any qualification.

Escape from Asylum.

For the offence of wilfully permitting, assisting, or conniving at the escape or attempted escape of a patient from an institution for lunatics, Section 323 of the Lunacy Act lays down a rather strangely limited punishment. The offender is to be "liable to a penalty not exceeding £20 nor less than £2." A man who was formerly a mental attendant at a St. Leonards home pleaded guilty at Hastings on May 18th to the charge of having aided and abetted the escape of Prince Ahmed Seif Ed Din, a certified lunatic, from Hastings in August, 1926. He brought his £20 to court and the full penalty was imposed, the chairman of the bench stating that it was a serious offence. The chief constable had observed that the maximum penalty was totally inadequate in a case of such a nature. When, if ever, our lunacy law receives its long-delayed amendment, perhaps Parliament will take note of this official opinion.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR OWN CORRESPONDENT.)

Infective Origin of Malignant Tumours.

AT the recent Surgical Congress the first subject of discussion was the problem of malignant growths. Prof. Heidenhain (Worms) put forward the view that carcinoma, cancer, and sarcoma have the same origin and are conveyed from one person to another by an agent still unknown. The transference of human carcinoma to mice is, he said, impossible, as the human cells are destroyed in the foreign organism by autolysis. He has therefore endeavoured to preserve the virus without the cells and has produced autolysates by keeping cells of human cancer in a thermostat for 20 to 30 days. The products of this autolysis were inoculated into mice by subcutaneous, intracutaneous, intramuscular, or intraperitoneal injections or into the liver; sometimes also fresh tumour pulp was used for injection. The result was that a growth developed after several months. Inoculation of carcinoma often evoked sarcoma, and vice versa, whilst in other cases neoplasms of both categories were produced. The clinical features of the growth in the mice were similar to those of human cancer, and the primary tumour often appeared at a point distant from the place of injection. Metastases also occurred and autolysate made from a metastasis gave the same results on injection as autolysates from the primary growth. More than 2500 mice were inoculated and malignant disease developed in 6 per cent. of them. The success of the inoculation was seldom obvious before six months had elapsed, more often after 6–12 months, and generally after about a year. Primary growths developed in nearly every organ, but never in the skin and only once each in the stomach, the gall-bladder, and the colon. Prof. Heidenhain believes that his experiments have proved that carcinoma and sarcoma are caused by an agent outside the body; it has not yet been possible to ascertain its nature.

Treatment of Traumatic Meningitis.

Prof. Nicolai Guleke (Jena) said that 80 per cent. of cases of fracture of the base of skull prove fatal from meningitis. Nevertheless he recommended that operation should not be attempted unless symptoms of meningitis develop. Lumbar or sub-occipital puncture is indicated when the point of entry of the infection has not been ascertained. The improvement following puncture is due not to removal of the germs, but to reduction of the cerebral pressure. Puncture is not without danger, as it may cause a local meningitis to become general. If puncture proves insufficient, open drainage of the brain, combined with laminectomy of the second or third lumbar vertebra is indicated. The mortality in 325 cases in which operation was performed was only 19 per cent.

Operation for Pulmonary Embolism.

Prof. Gustaf Nyström (Upsala) reported three cases of pulmonary embolism treated by the Trendelenburg operation. One patient lived 30 hours, one five hours, and the third recovered. Prof. Nyström said that as it is sometimes difficult to remove the embolus, he had used an aspiration pump. Dr. A. W. Meyer[1] (Berlin) recommended digital compression instead of the compression tube. Good results were reported by Dr. Fernström (Stockholm), who had had two cures in four operations, and by Dr. Stegemann (Dortmund), who said that a patient operated on four years ago is still in good health.

Avertin.

Dr. Bernhard Martin (Berlin) described his method, using avertin as an anæsthetic. He advises that an enema should be given on the preceding day and an injection of scopolamine and of narcophine one and a half hours before operation. A lukewarm solution of avertin is then administered per rectum half an hour before operation, the dose being 0·125 to 0·5 g. per kg. of body-weight. The method was used for 259 patients, whose ages ranged from 1 to 59 years; the cases included 104 laparotomies and renal operations. The method proved unsuccessful in 4 per cent. of the cases, in which a small quantity of ether had to be given as an adjuvant to secure complete anæsthesia. Prof. Seefisch (Berlin) reported 8 per cent. of failures in 104 cases. He had observed circulatory troubles, the blood pressure sometimes falling 20 mm., but death had never occurred as a result of the anæsthetic. Dr. Keysser (Lichterfelde) drew attention to the excretion of avertin by the kidneys, which makes it desirable in his opinion to administer diuretin.

X Rays in Prostatic Enlargement.

Dr. Bolt (Königsberg) reported 58 cases of prostatic enlargement treated by X rays; 12 of them were in the first, 13 in the second, and 33 in the third stage of the disease. In nearly half of the cases normal function of the bladder was obtained without residuary urine. Twenty-four patients were re-examined after two and a half years, and all of them could pass urine spontaneously. The method, Dr. Bolt says, should always be used in the first stage of the disease, and in the second and third stages the results are no worse than those of operation.

[1] Two cases reported by Dr. Meyer were mentioned by our Berlin correspondent last summer (THE LANCET, 1927, ii., 350). —ED. L.

MILDMAY MISSION HOSPITAL.—The new wing of this hospital in Bethnal Green was opened on Saturday last by Lady Cooper. The extension includes a new operating theatre, X ray, massage, and electrical departments. The number of in-patients has doubled in the last five years and the accommodation has become quite inadequate. Seventy-five doctors and 120 nurses have gone from the hospital to undertake missionary work, and 350 women have been given a measure of practical training to fit them for tending the sick both at home and abroad. The chairman of the council paid a warm tribute to the work of Dr. Henry White, the medical superintendent, and of Miss Woodhouse, the matron.

GENERAL MEDICAL COUNCIL.

THE PRESIDENT'S ADDRESS.

THE summer session of the General Medical Council was opened on May 22nd, Sir DONALD MACALISTER presiding. He had to record the death of one member of the Council since the last session and the retirement from various causes of five others. Dr. J. A. Macdonald, of Taunton, who died on April 23rd, was a Direct Representative, whose energy and skill in practical affairs deserved high praise. This vacancy on the Council would be filled by an election to be held during the summer. Sir Arthur Chance and Dr. J. A. Adams had retired owing to ill-health and their places had been filled by Sir William Taylor and Colonel G. H. Edington, M.D., representing respectively the Royal College of Surgeons in Ireland and the Royal Faculty of Glasgow. Three members, Dr. T. W. Griffith, Dr. D. Hepburn, and Dr. R. Howden, had retired at the expiration of their terms of office and the universities represented by them—Leeds, Wales, and Durham—had appointed Prof. J. K. Jamieson, Prof. A. W. Sheen, and Sir Robert Bolam to take their places on the Council. Of former members of the Council Sir William Church, Sir Dyce Duckworth, and Dr. H. W. Langley Browne had passed away; the President recalled the worthy example they had set to their successors. The President proceeded to refer to the end of his term of office, pointing out that for more than half of its lifetime he had been privileged to take part in the Council's fellowship, and recalling that 24 years ago the Council had entrusted him, then one of its junior members, with the onerous task of upholding the dignity of the President's chair.

The British Pharmacopœia.

The President announced that the privilege of practising in this country afforded to the practitioners of Quebec had been revoked, the reciprocal privilege of practice within its territory hitherto accorded to the registered practitioners of the United Kingdom having been withdrawn. He described the new proposals relating to the issue of the British Pharmacopœia (see p.1086 of this issue of THE LANCET), and expressed agreement with the terms of the unanimous report of the subcommittee. He commended as worthy of adoption the proposals for the readjustment of the practice of the Council in this matter, and recorded with special satisfaction the first conclusion—"that it is not necessary or desirable to make any alterations in the existing law relating to the preparation or publication of the British Pharmacopœia." If that view was accepted, it would rest with the Council, without waiting for legislation, to take immediate action for such alterations in practice as might be found necessary or desirable in view of the current revision of the British Pharmacopœia, 1914. Members of the Council would all be deeply and gratefully sensible of the singular ability and wisdom of the Chairman, Mr. Macmillan, and of the eminent service which through him the Lord President had rendered to the Council and to British pharmacopœial science and practice.

India.

He continued: "By your instructions the important reports on medical education in India furnished by Sir Norman Walker and Colonel Needham, with the conclusions of the Executive Committee thereon, have been communicated to the Secretary of State for India, and through him to the Government of India, and to the Indian universities. We have been officially assured that in the course of this year the question of the central control of standards of medical qualification in India will be dealt with in connexion with the pending inquiry on Indian Government generally; and further, that proposals are now before the Central Legislature for the establishment of an All-India Medical Council, with which this Council will be able to discuss and settle questions of reciprocal recognition of professional qualifications more conveniently and more satisfactorily than is possible in present conditions.

"The University of Calcutta, which has meantime applied for the recognition of its degrees, has brought into early operation its new regulations, revised so as to bring them into better accordance with the statutory requirements for practice in this country, and desired that its final examinations held under the amended regulations should be inspected and reported on by an inspector approved by the Council. The Indian Government, notified of this application, has deputed Lieut.-Colonel J. W. D. Megaw, C.I.E., M.B., I.M.S., to perform this service, in the absence of Colonel Needham on leave. His appointment has been duly approved, and the Executive Committee will probably have to meet in July to receive his report and others relating to India."

Legal Decisions Affecting the Council.

The President referred to two recent decisions, in the Court of Appeal and in the High Court, directly affecting the Council. The first had reference to an application for exemption from income tax payments on dividends received from investments of surplus income by the General Council and its branch councils. The court had decided that, though the Council was concerned by statute with medical education and registration, its functions were not so exclusively "educational" as to make it legally a "charity" within the meaning of the law.

The second decision, obtained at the instance of the Dental Board, disposed finally of the objection sometimes raised to the Council's proceedings in cases of conviction in England or Ireland for "misdemeanour" under Section 29 of the Medical Act, 1858. It had been asserted by counsel for the defence that in that section "misdemeanour" must be read as if the words were "indictable misdemeanour." The objection had, under legal advice, been again and again overruled from the chair. That ruling was now sustained by the judgment of the High Court. The Act for ratifying the Agreement on Medical Registration made on behalf of Great Britain, Northern Ireland, and the Irish Free State, had been passed into law, and the Agreement was now in force. The Departmental Committee appointed to consider the Registration of Opticians Bill, before which Mr. Eason and the President gave evidence on behalf of the Council, had reported against the Bill, which would no doubt now be dropped.

Finance.

The President concluded: "The publication in February of the Medical Register and of the Students' Register shows that the annual numbers of registered practitioners and of registered medical students continues to fall steadily from those of the post-war inflation period. In 1927 1941 new practitioners were enrolled, as compared with an average number of 2167 for the preceding seven years. The number of medical students entered in the Register was 1214, as compared with the seven years' average of 1441 per annum. The decrease in both figures is likely to continue for two or three years, more particularly as regards practitioners, for the effects of the drop in the number of students, which took place in 1923 and 1924 under the influence of the new regulations, are not yet exhausted.

"Though the decrease in annual registration is reflected in our financial statement, I am glad to say that, owing to prudent anticipation on the part of the Finance Committee, it has been discounted in advance. Our surplus for the past year is less than it has been, but it still reaches the substantial amount of £3031; while the assets of the General and branch councils have been increased by £2557. Our financial position is, in fact, sound and satisfactory."

A vote of thanks to the President for his address was proposed by Prof. J. B. Leathes and seconded by Sir Norman Walker.

Sir Donald MacAlister vacated the chair. On the motion of Sir Norman Walker, seconded by Sir John Moore, he was re-elected President for a further term of five years.

The Council then passed to the consideration of penal cases.

THE HARVEY TERCENTENARY.

BANQUET AT THE GUILDHALL

THE celebration of the Harvey tercentenary came to a fitting close, as far as the London ceremonies were concerned, with a banquet given to the delegates, and to a group of highly distinguished guests, by the Royal College of Physicians of London. For this purpose the College, through the kindness of the City of London, was enabled to receive the company in the Guildhall, where on Wednesday, May 16th, 450 persons assembled to commemorate the publication of the "De Motu Cordis" in 1628.

Sir John Rose Bradford, President of the College, presided, and, after the loyal toasts, the large company drank in silence to the Memory of William Harvey.

The toast of the Delegates was then proposed by Mr. Neville Chamberlain, Minister of Health, who set before the company an incisive picture of what the placing by Harvey of physiology upon rational grounds had meant to public health administration all over the world. With reference to his own responsibilities he described briefly our organisation for the maintenance of public health, and indicated that every branch of all these activities could be said to be regulated by the desire to maintain among the people a healthy circulation. "Our preventive medicine," he said, "is based on Harvey; the enemies against which we war are the factors which upset the balance of man's physiology, and the success which we obtain in the contest is due fundamentally to Harvey's discovery." He concluded by referring to the international character of disease, which knew no frontiers, so that the resources of all nations should be pooled to set up a common defence. He coupled with the toast the names of Prof. A. Castiglioni, the delegate from Harvey's own University of Padua, and Prof. W. H. Welch.

Testimony from Padua.

Prof. Castiglioni, speaking at first in English with eloquence and fluency, drew an admirable picture of the glories of the University of Padua at the time when Harvey was acquiring there the fundamental anatomical knowledge upon which he later erected his wonderful discovery. At that time, he said, Galileo Galilei was doing for the circulation of the heavenly spheres what Harvey was later to do for the circulation of the blood, while the men working at Padua made of the university a veritable centre of the anatomical knowledge of the world. Then, pleading for the employment of the language of Dante in setting before the audience the connexion of Harvey with Padua, he gave a fine example of what an impassioned oration sounds like in the most sonorous language in the world. He spoke of Harvey's independence and courage and of the genius which enabled him to comprehend the inter-relations of his work with that of his predecessors and contemporaries, and said that he was proud to be the spokesman for his fellow delegates in testifying to the glory of Harvey. "Harvey," he said, "discussed his researches with his co-workers in Italian, and for his armorial motto adopted the Italian words 'più arde e più splende.' We note the characteristic virtues of the English in Harvey's loyalty and sense of honour. We applaud the man of science, while we remember the man of noble courage and character, always true to his colleagues, his science, and his king; well knowing, as he says in his book, that his discovery would make for him many enemies, nevertheless, he must publish it because the truth is for him a holy law. He was, and we of Padua can say it with pride, the worthy disciple of Galileo, who to the whole scientific world gave vision where they had been blind. I must also recall to your memory the ghosts of those great men who took the earliest steps in scientific research, Vesalius, Leonardo da Vinci, who with marvellous foresight contributed to the foundations of anatomy while ranging through the knowledge of the time, Realdo Colombo, Fallopius, Cesalpinus, the noble philosopher and teacher, and Fabricius Ab Acquapendente, who discovered the valves of the veins. In this great company Harvey stands in his right place, and we revere him as the prime discoverer of the physical and physiological significance of what he had learned and observed. In Harvey's days my language was used by the scientific men of the whole world; it was spoken at the Court of Charles I., the great patron of Italian art, and in France where Maria dei Medici was the Queen of Louis XIII. and it is fitting that in that language I should address you, though speaking for the Delegates of the academies and universities of all the world. I thank you for the opportunity which you have given us all to take part in this Celebration, and I record our admiration of your country."

Prof. Welch, whose studiously quiet delivery was in acute contrast to the fiery eloquence of Prof. Castiglioni, alluded happily to the fact that at the time when Harvey made his great discovery his country and Great Britain were one. He spoke in reference to the scientific proceedings with the highest admiration of the demonstrations at University College, declaring that such remarkable reproduction of Harvey's researches must have come as a revelation to all who saw them and would remain as an inspiration to them.

The Order of Honorary Fellows.

In giving the next toast, the Honorary Fellows, Sir John Rose Bradford remarked that the institution of this order was a departure; in a sense, he said, the Marquis of Dorchester, who, after the destruction of the College library in the Great Fire, bequeathed his magnificent collection of books to the College, might be regarded as an honorary Fellow, for he was a layman, while the late King Edward VII. had also accepted from the College a Fellowship. But the institution of an order of honorary Fellows was an innovation. In accordance with their decision to create this order the College, he said, had decided to ask the Earl of Balfour, Sir Ernest Rutherford, Prof. I. P. Pavlov, of Leningrad, and Prof. K. F. Wenckebach, of Vienna, to accept the highest honour which it was within the power of the College to confer. He briefly justified the fitness of the choice. The learning and wisdom of Lord Balfour, he said, needed no dissertation from him, his deep interest in science and his many services rendered to science being well known to all. In Sir Ernest Rutherford, the President of the Royal Society, the College were honouring not only a great philosopher, but the figurehead of a great association; Prof. Pavlov, of Leningrad, would be recognised by the world as the doyen of physiology, while Prof. Wenckebach, of Vienna, had won universal fame by his studies along lines similar to those which the great Harvey had laid down. Replies were made by Prof. Wenckebach and Sir Ernest Rutherford, the latter of whom explained how Harvey had come to visualise the correct physical forces that must be concerned in the circulatory system, saying that he was the first man to apply physics to medicine.

Harvey and Linacre.

The health of the President was proposed in eloquent and humorous terms by the Archbishop of York, who said: "I have one link with this College which I greatly value—it is that its principal founder and first President, Thomas Linacre, became 400 years ago, what I still am—a Fellow of All Souls College, Oxford; and as the founder of the College shared with me the fellowship of that delightful home, I may claim to stand towards the College in the position of Founder's Kin. I venture to dwell for a moment on the claim of Thomas Linacre to special honour, even on an occasion specially commemorating William Harvey. Linacre represent

ıe union of medical science with literature and holarship; he was one of the first students of reek, a pupil of Grocyn and friend of Erasmus, olet, and Thomas More—that band of scholars ho might have changed the course of history if ıly men were willing to be guided by 'sweetness ıd light.' I hope that this union may always ntinue—Harvey himself was a considerable scholar -and that in spite of the claims of highly specialised udy, the goodly succession of 'medical humanists' ay still be maintained. Again, Linacre represented e union of medical science and the Church. He was mself, for the last 15 years of his life, in Holy Orders. o doubt this union was for a time somewhat pressive to medical science. Theology—the queen sciences—has been sometimes, like other queens, alous and somewhat despotic. Her control of edicine lasted long. Only seven years before the oyal College of Physicians obtained its charter, statute was passed requiring all those who had not aduated in medicine at Oxford and Cambridge, d who desired to practise medicine in London, be approved after examination by the Bishop of ndon or the Dean of St. Paul's. How interesting would be if that requirement was still in force! ıere would then be two schools of London physicians those who had graduated in the cheerful optimism the Bishop of London, and those who had graduated the philosophic pessimism of the Dean of St. ul's, or even in that sombre study of eugenics, ıich creates in some of us the uncomfortable feeling at it might have been better if we had never been rn! Now, however, medical science has been set e to go upon its own way unhindered, and the ationship of medicine in the Church may be, and ght to be, one of cordial coöperation. For each eds the other in its own work. Medicine will ıch the Church that the life of mind or even spirit fulfilled through and conditioned by the body; e Church may remind medicine that the body penetrated, influenced, and controlled by the spirit. ır common ground is that the body, mind, and rit are not mere separate departments of man's ture, but parts of one whole organism which must studied as a whole. In this study the Church d medical science should work together in the spirit students, with open minds as befits the disciples truth. As I propose this toast, what moves me the thought of the constant patient research which es on under the encouragement of the College, and immediate application to human needs. I don't nk there is any profession in which research, ching, and practice are so close or more truly ed in one great enthusiasm of service. We have been thinking of William Harvey pursuing his at researches in the very wards of St. Bartholo- w's; and I like to think that there may be men w in the wards of our great hospitals impelled by ger quest of knowledge and by an equally eager sire to lift the burden of human suffering, and who y be on the brink of some new discovery; that, use the words of Milton, 'there are some worthies w breathing in the air of England who shall be e Harvey] her leaders to such a deliverance as ll never be forgotten by any revolution of time t this world hath to finish.' Of all this great nistry of research and healing the Royal College the heart. Is it fanciful to-night to speak of its n action as resembling that which William Harvey covered? In that heart all the results of research, ich is the very life-blood of science, are tested; nce they are communicated through all the veins l arteries of a devoted profession to the whole mmunity; and a return is made to the heart in admiration and gratitude of the people. In ler that we here, their grateful guests, may take share in that admiration and gratitude, I ask to honour the toast of 'The Royal College of ysicians,' and I couple with it the name of one o has signally illustrated the union of research l practice—the distinguished President."

Sir John Rose Bradford briefly replied.

A Distinguished Company.

The distinguished company present included, in addition to the delegates and the speakers already mentioned, Their Excellencies the French, the German, the Italian, the Belgian, the Austrian, the Greek, and the Finnish Ambassadors and Ministers, the Archbishop of Wales, Cardinal Bourne, the Deans of Westminster and St. Paul's, the Chief Rabbi, the Lord High Chancellor, the High Commissioner for New Zealand, the President of the Royal College of Surgeons of England, the President of the Royal Academy, the President of the Society of Antiquaries, the Recorder of the City of London, the Vice-Chancellor of the University of London, and the Regius Professors of Medicine at Oxford and Cambridge. The following acted as Vice-Chairmen: Dr. Raymond Crawfurd, Registrar; Dr. R. O. Moon, Assistant Registrar; Dr. Sidney Phillips, Treasurer; Dr. Arnold Chaplin, Harveian Librarian of the College; Dr. J. W. Carr, Dr. F. J. Poynton, and Dr. A. P. Beddard, Censors of the College; Dr. H. Morley Fletcher, Sir Hector Mackenzie, Sir StClair Thomson, Dr. J. H. Abram; and Mr. H. M. Barlow, Secretary of the College.

THE VISIT TO OXFORD.

A number of the delegates to the celebration of the Harvey tercentenary visited Oxford on May 17th and were entertained at luncheon in Harvey's College by the Warden and Fellows of Merton. In the morning the Regius Professor of Medicine, Sir Farquhar Buzzard, the Dean of the Faculty, Dr. Ainley Walker, and a number of other members of the University conducted the visitors in groups to different centres of particular interest, and at 1.15 the different parties re-united at Merton College, where they were met by the professors in the Faculty of Medicine and were received by the Warden and Fellows of the College. Luncheon was served in the College Hall to about 100 guests, and in the centre of the hall were displayed some of the College books relating to the period of Harvey's wardenship, and a bursarial account showing his signature was exhibited. The Warden, Mr. Thomas Bowman, expressed the pleasure felt by the College in welcoming and entertaining the delegates, and a brief address followed from Sir John Rose Bradford. A short account of Harvey's connexion with Merton, drawn up by Prof. H. W. Garrod, Fellow of the College, was presented to each of the guests at luncheon.

THE VISIT TO CAMBRIDGE.

On May 18th the delegates proceeded to Cambridge, a certain number of them making the journey by car in order to visit the burial place of Harvey at Hempstead in Essex. On arrival at Cambridge they were entertained at luncheon by the Master of Gonville and Caius, Sir Hugh Anderson, and the Fellows of the College from which Harvey graduated. A brief address and welcome to the guests was given by the Master, to which Sir John Rose Bradford replied. The visitors were then taken, as on the previous day at Oxford, to various important university institutions.

HOSPITALS AND MOTOR ACCIDENTS.—It appears from a letter contributed to the *Times* of May 18th by Sir Arthur Stanley, as President of the British Hospitals Association, that insurance companies are now prepared to pay the cost of hospital treatment of insured persons upon receiving from the hospital a statement of the expense incurred.—A remarkable example of the seriousness of the situation created by the great increase in the number of motor accidents is furnished by last year's experience of Chiswick Hospital, an institution of 42 beds, which was established and is entirely maintained by a private benefactor. During 1927 2431 casualty cases were treated. The number is explained by the fact that the Chiswick High Road is one of the most crowded exits from London and the principal avenue of access to the Great West Road. Almost the whole of these accidents occurred in that thoroughfare, but they do not represent the entire number, since many others were treated at the West London Hospital at Hammersmith.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1927 statistics of five districts of varying local government status:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Diarrhœa, &c., under 2 years.	Maternal mortality from childbirth.
Plymouth C.B. (211,650)	16·5	12·0	1·00	1·58	2·6	1·4	61/32	4·6	7·7
Southport C.B. (78,670)	12·2	13·6	0·61	1·82	2·9	2·0	48/20	3·1	4·2
Swindon B. (57,150)	14·5	11·2	0·96	1·26	2·3	2·3	47/25	2·4	1·2
Barnstaple R.D. (18,950)	14·4	13·3	1·0	1·1	2·6	1·7	65/–	7·3	0·0
Ventnor U.D. (5,015)	11·8	15·3	0·6	1·0	3·2	3·4	17/–	0·0	0·0

Plymouth.

Dr. A. T. Nankivell describes 1927 as a year of much progress. Health education work has been enormously increased. A monthly health magazine with a circulation of 10,000 has been distributed at a slight profit. It is realised that this is a pioneer effort and that it has to be made more attractive in order to get at the people who most need instruction. Health propaganda films are generally too scientific, says Dr. Nankivell, and need to be humanised and made more entertaining. Some 450 lantern slides were exhibited 16,470 times in Plymouth cinemas and theatres. Advertisements appear in the trams and stations. A Runsyne machine with an illuminated health message has been fixed at one tram terminus. The local press helps. In fact, nobody in Plymouth needs to be ignorant of the primary laws of health. Swilly Hospital has been made into an ideal place for late cases of pulmonary tuberculosis in women. Additional outside accommodation has been found for pulmonary and non-pulmonary tuberculosis. Photographs are given of a new children's ward and a school hut at Didsworthy. An X ray apparatus is needed to enable artificial pneumothorax treatment to be carried out.

The maternity and child welfare work increases. There were 3502 births and 981 new cases attended the six antenatal clinics. Over 400 children between 6 months and 5 years of age have been immunised against diphtheria at the special clinic opened in January. The new cases treated at the ultra-violet light clinic numbered 130, mostly rickets, but including 16 cases of malnutrition and 9 of skin diseases. The results were claimed to be "very encouraging." Medical practitioners have coöperated in the investigation of the causes of puerperal pyrexia. At the antenatal clinics about 22·5 per cent. of the patients were found to have some discharge, but among the 41 (excluding the mild) cases of pyrexia investigated, auto-infection from a pre-existing discharge was not demonstrated and the influence of poor surroundings did not appear to be marked. In one case the home was dirty and two cases were nursed by untrained women with "elementary ideas of asepsis." In one case there was a suspicion of transmission of infection from a previous case. Three cases occurred simultaneously in a nursing home. Altogether 23 cases occurred in institutions "where the conditions would certainly be more favourable than the usual home surroundings." The staff of health visitors is inadequate for the work and two more "centres" are needed.

Good work is being done in house renovation under Section 3 of the 1925 Act, by which, in the default of the owner, the town council does the work and makes the cost a first charge on the property. It is estimated that £100,000 has been spent during the last three years in repairing insanitary houses. Two years ago three insanitary areas were scheduled, but little progress has been made. Plans have, however, been prepared for the reconditioning of two areas of "squalid streets." The supervision of the milk supply has been strengthened by visits of the inspector to the farms during the early morning milking. One of the largest dairies has installed a modern pasteurising plant and another sells sterilised milk. There is a marked increase in the sale of "designated" milks. The municipal hospitals and "centres" use Certified milk. Among 134 milk samples examined for tubercle none was found to be infected. The searching out of congenital syphilitics continues. Out of 4000 school-children examined, 86 were found to be affected. Altogether 118 children came under treatment during the year. Keratitis is the chief trouble. Many when first brought to the clinic cannot see, but improve so much under continuous efficient treatment that in time they are able to read and lead a practically normal life. A "rheumatic register" started at the beginning of the year includes the names of 56 school-children, some apparently in good health, some with chorea, and some with the heart affected. Better hospital arrangements are needed for the children attending the orthopædic clinic.

Oysters from the Tamar and St. Germans beds have to be relaid at the mouth of the Yealm for purification, and the attempt was made during the year to use the Yealm beds for breeding and rearing. The catch from the first-named beds shows a decline which has been attributed both to overfishing and contamination by oil. Complaints of the pollution of the Sound by oil, acid, and sewage have been investigated. It is suggested that the Admiralty should prohibit the discharge of oily matters within the 3-mile limit. On the other hand, it is thought that much of the oil may originate with the waste-oil of the 12,000 motor vehicles of the borough discharged into the Sound via the sewers. Investigation of the currents and winds seems to indicate that the bathing pools are adequately protected from the western but not from the eastern sewage outfalls.

The report for the Port contains a welcome reference to the conspicuous improvement in the crew quarters of newly built vessels as regards position and construction of living space, bathrooms, and room set apart for meals. At the same time it is pointed out that the rat-proofing of cabins, crews' spaces, and store rooms should be made compulsory in all newly constructed vessels. Energetic efforts were devoted to rat destruction. A new rat-proof warehouse is cited as a model for imitation. Rats infected with plague, as a sequel to human plague in the Argentine, were found on grain ships from Rosario in the port of London. The examination of 122 black and brown rats caught on three grain ships leaving Rosario while plague was prevalent in that neighbourhood gave a negative result in the case of Plymouth.

Southport.

Dr. G. C. Barnes reports that the new isolation hospital was opened in October by Sir G. Newman, who declared that he knew of no existing hospital better adapted and designed for the work contemplated, a verdict which is supported by excellent photographs of the buildings and equipment, including the sanatorium wards for tuberculosis. The X ray block and laboratory is to be completed this year. Since the first sunshine recorder was erected at Southport 36 years ago, there have only been three more sunless years than 1927. The recorded hours were 1382·4, or 148·5 hours below the normal. During the early months an epidemic of severe influenza accounted for 56 deaths. Towards the end

f the year an artificial sunlight installation was rovided for the tuberculosis, school, and child elfare departments.

Swindon.

Dr. Dunstan Brewer describes how Swindon was uddenly visited by an epidemic of influenza about an. 15th, which reached its peak on the 24th and ollapsed on Feb. 15th, leaving nothing behind it. The apid increase of pneumonia notifications in the second eek of January heralded the epidemic which attacked bout a third of the inhabitants. The 56 deaths ttributed to it included those of 17 persons over 0 and 5 non-residents. The deaths were due in nearly qual proportions to toxic and pneumonic forms. n June a mild type of epidemic pneumonia appeared. n mid-August 5 cases of pneumonia were admitted to ospital, 2 from the borough and 3 from outside, all f which proved fatal. The mother of one case died rom paratyphoid and the brother-in-law of another eveloped cerebro-spinal meningitis and recovered. His wife, who was a carrier of the meningococcus, ad visited her brother, the only one of this batch of atal pneumonias who did not have cerebral disturbnce. Dr. Brewer regards the prompt notification of neumonias as of prime importance in cold climates as hey are generally the first evidence of approaching pidemic trouble. If a medical officer of health can ely upon his register of pneumonia notifications he ill not be caught unawares by epidemics of a angerous or unusual character. In Swindon neumonia has the first indisputable claim upon the ccommodation of the isolation hospital. During 927, 63 cases were removed to hospital, of whom 4 died (22·2 per cent.), while 139 were treated at ome, of whom 44 died (31·6 per cent.). As pneumonia n England and Wales causes five times as many deaths s all other epidemic diseases put together and is in ost infections the chief danger to life, the Ministry oes well, says Dr. Brewer, to urge that it should ccupy a first place in the attention of sanitary uthorities. A table shows that during the last even years there have been 1013 notifications of neumonia in Swindon with 323 deaths, and that the ase-fatality was 19·02 per cent. for hospital-treated nd 34·7 per cent. for home-treated cases respectively. As in former years all the deaths of children under 7 years of age were investigated and correlated with ie known facts of their medical history with a view to ie ascertainment of the main factor responsible for using death. There were 65 deaths under 17 ears, as compared with 94 and 103 in the two preceding ears. There were 830 births during 1927 and 338 ew cases attended the antenatal clinic. There is a reat need of hospital beds for in-patient antenatal eatment. When the proposed extension of the ictoria Hospital has been carried out and the ew maternity hospital has been completed (hoped r in 1929), Dr. Brewer thinks the town will be asonably equipped except for mental and tuberculosis ses.

During 1927, 289 (including 4 municipal) houses were ected within the borough and 100 on the outside rporation estate. As the population declined by 0, overcrowding has been theoretically relieved to e extent of 1300 persons. The small amount of rious overcrowding which actually exists in vindon can only be actually relieved by the erection the cheapest possible houses, let at an uneconomic nt.

Barnstaple.

Dr. J. R. Harper's rural district, which covers 0,000 acres, is mostly agricultural but has a fishing dustry and is a holiday health resort. He says the andard of living has considerably improved in cent years, but that much remains to be done in the placement of picturesque but badly lighted and -ventilated cottages. There were no notifications of erperal pyrexia and only one of typhoid fever, a vere case at a dairy farm, the origin of which uld not be traced but which led to no other cases. widespread epidemic of influenza is reported, deaths being registered from it and 12 from pneumonia. Practically all the schools were closed for two to three weeks during February and March from this cause. No serious complaints about the water-supply were received, except from Combe Martin. During the year 33 new wells were sunk.

Ventnor.

Dr. Reginald T. Cooke mentions that three-quarters of the 77 deaths in this urban district were those of persons over 65 years of age. There were 57 births and one infant death. Scarlet fever was unusually prevalent and caused 1 death ; 7 deaths were ascribed to influenza. The water-supply, from the chalk, is "intermittent" to the higher levels of the town, and Dr. Cooke thinks that tenants frequently do not exercise sufficient care in having their storage tanks periodically cleansed. The hours of bright sunshine registered at the Ventnor Hospital were 1771·6 and at Ventnor Park 1672·1. These are compared to Brighton with 1666·2 hours. Ventnor held a good position among 12 towns, which keep records of ultra-violet rays. For 3 months it was first, for 2 months second, and for 3 months third.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 12TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 319 (last week 321) ; scarlet fever, 1609 ; diphtheria, 1110 ; enteric fever, 55 ; pneumonia, 1267 ; puerperal fever, 32 ; puerperal pyrexia, 91 ; cerebro-spinal fever, 11 ; acute poliomyelitis, 7 ; acute polio-encephalitis, 1 ; encephalitis lethargica, 21 ; continued fever, 1 ; dysentery, 9 ; ophthalmia neonatorum, 137. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 25 counties : London, 5 ; Bedford, 6 ; Berks, 1 ; Buckingham, 1 ; Derby, 5 ; Durham, 55 ; Essex, 1 ; Gloucester, 5 ; Hertford, 3 ; Lancaster, 22 ; Leicester, 2 ; Lincoln, parts of Holland, 2 ; parts of Lindsey, 5 ; Northumberland, 7 ; Nottingham, 11 ; Soke of Peterborough, 1 ; Salop, 1 ; Stafford, 20 ; Surrey, 1 ; Warwick, 9 ; Yorks, North Riding, 15 ; West Riding, 87 ; City of York, 3 ; Glamorgan, 16 ; Monmouth, 35.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on May 15th–16th was as follows : Small-pox, 35 ; scarlet fever, 1597 ; diphtheria, 2163 ; enteric fever, 34 ; measles, 1160 ; whooping-cough, 148 ; puerperal fever, 19 (plus 15 babies) ; encephalitis lethargica, 66 ; "other diseases," 24. At St. Margaret's Hospital there were 17 cases of marasmus, and 10 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 (0) deaths from small-pox, 3 (0) from enteric fever, 71 (37) from measles, 4 (1) from scarlet fever, 44 (10) from whooping-cough, 39 (14) from diphtheria, 44 (10) from diarrhœa and enteritis under two years, and 80 (10) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred at Bristol, West Bromwich, and Salford. Of the 34 fatal cases of measles outside London 7 were reported from Liverpool and 3 from Sheffield ; while the figures in Edinburgh, Glasgow, and Dublin for the same week were 5, 7, and 6. Of the 34 fatal cases of whooping-cough outside London 10 were reported from Birmingham and 4 from Liverpool. The two deaths provisionally classified to small-pox were assigned to Bradford and Middlesbrough.

Dr. C. V. Dingle, medical officer of health for Middlesbrough, informs us that the man who died there was 77 years of age and had long been an inmate of the Union Infirmary. There had been some cases of small-pox in the institution and he developed the disease and died one day after the rash appeared. He was in a septic condition and very feeble before he contracted small-pox. He was too ill at the time of the outbreak to revaccinate and his vaccination in infancy was indefinite. He said he had been vaccinated, but no visible marks could be made out.

The number of stillbirths registered during the week was 314 in the great towns, including 57 in London.

Correspondence.

"Audi alteram partem."

ENCEPHALO-MYELITIS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—In an account of Encephalo-myelitis following Vaccination, published in the *British Journal of Experimental Pathology* in 1926 (vol. vii., pp. 181–222), which you made the subject of a leading article on Sept. 4th, 1926, we pointed out (p. 186) that —

"the most characteristic feature of the inflammation is the occurrence in the white matter of a broad perivascular zone of softening in which infiltration is relatively slight (Figs. 4, 6, 7)";

and again in a summary of "the chief *characteristics of the inflammation*" (p. 190):—

"The most characteristic histological feature is the zone of perivascular softening in the white matter."

Further, in a histological comparison with poliomyelitis we said (p. 200):—

"the cardinal differential feature by which the conditions can be separated at a glance is the occurrence in post-vaccinial encephalo-myelitis of perivascular zones of softening of white matter";

and in a similar comparison with over 40 cases of encephalitis lethargica we said (p. 204):—

"Finally, we have not found in any case the perivascular zones of softening that are so conspicuous in the white matter of post-vaccinial encephalitis";

and again, on the same page,

"The most striking differential feature of the post-vaccinial cases is the zone of softening round vessels in the white matter."

In the "conclusions" (p. 219) in the comparison of post-vaccinial encephalitis with poliomyelitis it is said:—

"A conspicuous peculiarity is the presence of broad zones of softening round vessels in the white matter";

and in the comparison with encephalitis lethargica:—

"here again the zones of perivascular softening are a conspicuous peculiarity."

The softening is described as follows (p. 186):—

"This softening was demonstrated by the Weigert-Pal method in only one portion of tissue from Case 5, but the loss of medullated sheaths is conspicuous in sections stained deeply with hæmatoxylin, particularly Weigert's iron-hæmatoxylin. The loss of the rings corresponding to the medullary sheaths is usually associated with a spongy vacuolation of the glial net; the cytoplasm of the infiltrating cells tends to be vacuolated and occasionally is typically foam-like."

This description follows immediately upon the reference to Figs. 4, 6, 7, in illustration of our perivascular softening, and the completeness of the destruction of medullated sheaths is very clearly shown in the drawing (Fig. 7) of the highest magnification. We considered the three changes described to represent a rapid, massive destruction of medullated sheaths, some absorption of water and the presence of fat granule cells: phenomena characteristic of softening of the central nervous system when not complicated by colliquative necrosis of the supporting tissues. The employment of the term "softening" thus emphasised the apparent rapidity and uniformity of the destruction of myelin in comparison with that in the so-called primary tract degenerations. A reference on page 204 to two cases of acute disseminated sclerosis gives further evidence that loss of myelin was the essential feature of our perivascular softening.

Dr. J. R. Perdrau in a paper on the Histology of Post-vaccinial Encephalitis, contributed to the *Journal of Pathology and Bacteriology* (1928, vol. xxxi., pp. 17 to 32), found that —

"perivascular demyelination is the essential and characteristic lesion of post-vaccinial encephalitis" (p. 28).

By special stains he confirmed (p. 20) our conclusion that the destruction of myelin was exceptionally rapid. No evidence of perivascular demyelination could be found in five cases of encephalitis lethargica studied by either the Weigert-Pal or the Marchi method or by both. Perivascular demyelination was not observed in pieces of spinal cord from poliomyelitis, but the material examined was considered inadequate for a satisfactory comparison. Whilst making numerous references to our work he only mentions our observation of the destruction of myelin in a footnote (p. 18), and says we laid little stress upon the observation. The footnote reads:—

"The term 'softening' is here used in its ordinary sense of necrosis when applied to certain lesions of the central nervous system (e.g. the result of arterial thrombosis). Turnbull and McIntosh use it for an earlier stage of the process, described here as demyelination. They associated this 'softening' with 'loss of the myelin sheath' (p. 186) but laid little stress on the observation."

In Case 7 we found "a zone of softening and infiltration along each edge of the anterior septum" (p. 190); Dr. Perdrau (p. 20) refers only to our having recorded infiltration of this site. We drew throughout the paper a sharp distinction between perivascular softening and perivascular infiltration alone. Thus (p. 186):—

"Within the substance of the brain and cord infiltration is conspicuous and is essentially perivascular. Infiltrations within the adventitial sheaths or immediately round the sheaths of the vessels, forming sharply-defined vascular sleeves, are numerous. . . . The predominating lesion is a broad zone of less dense, 'extra-adventitial,' perivascular infiltration (Fig. 1). In portions of the grey matter in which this infiltration is at its maximum the perivascular distribution is less distinct, the infiltration becoming diffuse (Fig. 3). Such zones of extra-adventitial perivascular infiltration occur in the white matter (Fig. 2), but the most characteristic feature of the inflammation is the occurrence in the white matter of a broad perivascular zone of softening in which infiltration is relatively slight (Figs. 4, 6, 7)."

Then follows the description of softening which has already been quoted. Perivascular infiltration was not described as peculiar to post-vaccinial encephalitis. In the description of poliomyelitis perivascular infiltration is not denied; it is only said (p. 200):—

"The perivascular nature of the extra-adventitial infiltrations is not conspicuous."

In the description of encephalitis lethargica (p. 203):—

"In the formation of vascular sleeves, especially in initial stages, cells immediately outside the adventitia take considerable share here as in post-vaccinial encephalitis. The disposition of the cells of the extra-adventitial infiltrations within the grey matter is very similar: a perivascular arrangement is usually distinct, . . . in one case glial cells with elongated oval nuclei are abundant round vessels in the grey matter so as to recall the perivascular infiltration without softening occasionally seen in the white matter in post-vaccinial encephalitis."

Dr. Perdrau, however, talks (p. 25) of "the extra-adventitial infiltration which Turnbull and McIntosh look upon as characteristic of post-vaccinial encephalitis," and in his summary (p. 31) says that post-vaccinial encephalitis is characterised by "demyelination (the extra-adventitial infiltration or softening of Turnbull and McIntosh)."

From careful perusal of Dr. Perdrau's paper, especially the second paragraph of page 23, we believe that this second discrepancy may be due to Dr. Perdrau possibly having found by the methods of Weigert-Pal and Marchi loss of myelin in our "broad zone of less dense, 'extra-adventitial,' perivascular infiltration" (p. 186), as well as in our zones of "softening." If that is so, it has not been clearly stated. We find it necessary to draw attention to both discrepancies, because Dr. Perdrau's paper has to our knowledge caused many to believe that we had failed to recognise that perivascular demyelination was a characteristic of post-vaccinial encephalitis and the cardinal feature differentiating that condition from poliomyelitis and encephalitis lethargica. Yet in reality it was the recognition in 1912 of the

perivascular destruction of myelin which first drew our attention to post-vaccinial encephalitis, and it was this perivascular destruction of myelin on which we laid such stress in a report in January, 1924, on the histology to the first commission appointed by the Ministry of Health, in a demonstration to the commission in the following month, which included the actual fields from which our figures 7 and 8 were drawn, and in our publication of 1926 referred to above.

We are, Sir, yours faithfully,

HUBERT M. TURNBULL.

LEGAL AID SOCIETIES AND THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—The case decided in the King's Bench Division recently in which damages were awarded against a solicitor for maintenance and champerty—proceedings by which a person bargains to carry on a suit in which he has no legitimate concern in consideration of the damages which might be recovered in the suit—is of interest to the medical profession. Legal aid societies are more or less exclusively engaged in claims for personal damages. They get their information as to accidents from different sources. To make a claim they require a solicitor and doctor who are willing to work on a speculative basis. The poor person would appear to have little or no other alternative but to seek their aid when claiming damages to which they might be entitled. As a result of this case, and having regard to the medical aspects involved, will not the General Medical Council take action? Apart altogether from any question of liability, the first member of the "syndicate" to receive actual cash out of one of these cases is the doctor acting on behalf of the solicitor who gets a fee from the other side for a consultation. It is in this direction that I would suggest a very necessary and equitable reform in the present state of affairs. In my opinion, in cases of this kind, "running down," "third party," &c., no such consultation fees should be paid till liability is admitted or established. Medical fees and expenses could then be included in the costs of the case whether it was settled in or out of court.

I am, Sir, yours faithfully,

J. J. SCANLAN.

EPIDEMIC CATARRHAL JAUNDICE.

To the Editor of THE LANCET.

SIR,—Although engaged in other problems now, I read with much interest Dr. Athole Ross's note on the pathology of epidemic catarrhal jaundice in your issue of March 24th (p. 599). May I first remark that Dr George Buchanan will probably take exception to an observation therein erroneously attributed to him, and quoted from the Ministry of Health Report No. 42, in which certain views of the present writer are cited.

My main object, however, in writing is to explain that my translation to South Africa in 1926 was responsible for not fulfilling an implied promise in a statement mentioned by Dr. Ross, "that fresh material is being investigated with a view to discovering bacterial infection." I had become convinced by that time, both from clinical and bacteriological experience of the small outbreaks of jaundice amongst school-children I had carefully investigated, that none conformed from the aspect of clinical findings, incubation period, bacteriological and experimental results to that of spirochætal jaundice. Apart from the report of a small epidemic of spirochætal jaundice by D. M. Pyon and myself, published [1] in 1925, where cognisance was taken of both incubation and invasion periods to strengthen the diagnosis, few if any other epidemics of mild jaundice in Britain have been definitely proved to be of spirochætal origin. The presence of spirochætes in the urine of young subjects with mild jaundice is in my opinion a mere trap for the unwary, which only experience teaches one to avoid. Hence in outbreaks of jaundice amongst school-children or in families, where case-to-case infection rapidly occurs, spirochætal jaundice can be ruled out, which opinion has also been expressed by such authorities as Stokes and Ryle. I would further add to this—in spite of the presence of spirochætes obviously not leptospiræ in the urine, as the latter are so distinctive whether alive, degenerated, or dead.

In conclusion I would like to mention that the future line of investigation I had in mind in 1926 was to attack the problem of epidemic catarrhal jaundice from the point of view of a descending infection, possibly from the naso-pharynx, as a number of my cases exhibited initial catarrhal symptoms. So to the suggestion made by Dr. Ross regarding complete bacteriological examination of the excreta, I should like to add that naso-pharyngeal swabs be examined at the onset, and most important of all the application of bile drainage, which I had chiefly in view, for the purpose of a bacteriological examination of both duodenal contents and bile. This, however, I realised would present no little difficulty in such young subjects, but it may be practicable in older school-children.

I am, Sir, yours faithfully,

GEORGE BUCHANAN, M.D., D.P.H.,
Superintendent, Routine Division, South African
April 25th, 1928. Institute for Medical Research.

INDICATIONS FOR TONSILLECTOMY.

To the Editor of THE LANCET.

SIR,—In your issue of May 12th Dr. C. J. McSweeney writes: "To say what is or is not an healthy tonsil is a very much more difficult task than to record whether or not the tonsil is of normal size," and further, "If enlargement is to be taken as the expression of past infection, it is clear that the Cardiff figures do not support the conclusion of the B.M.A. Subcommittee." As I believe mere enlargement is not to be taken as the expression of past infection, I suggest the following indications for tonsillectomy.

I have followed the results of Crowe's[1] work, which I present here, in deciding whether tonsils are diseased or not. There is normally a hyperplasia of the tonsils and adenoids between the ages of 3 and 12 years. Tonsils and adenoids are physiological important parts of the mechanism that protects the lower air passages from dust and organisms. An enlarged tonsil ought not to be considered diseased unless the tonsillar lymphatic gland[2] is enlarged or the patient has had an attack of tonsillitis or a peritonsillar abcess, or the anterior pillars are adherent to the tonsils, or pus can be squeezed from the tonsils by making pressure on the anterior faucial pillar, or the tonsil has been partially removed or cauterised, causing occlusion of the crypts. Tonsils that have been damaged by previous infections or partial operative procedures are prone to give rise to general disorders following an acute attack of chronic tonsillitis. If a child has a focal infection and has had one attack of acute follicular tonsillitis, I would remove the tonsils, as the absence of signs would not exclude the presence of a small chronic intra-tonsillar abscess. Thus, even in the presence of a focal infection, I would not remove large tonsils unless one of the above signs demonstrating infection was present.

The tonsils most prone to cause focal infection are, I believe, the small fibrous tonsils, from which pus can be expressed or which are adherent to the faucial pillars. In children I chiefly rely on the enlargement of the tonsillar cervical gland as the sign of tonsillar infection. This gland is palpated just above the hyoid at the anterior border of the sterno-mastoid, if the examiner stands behind the patient. Another

[2] Cervical Lymph Nodes, Ann. Surgery, 1905, xlii., 49–74.

sign of chronic tonsillitis, to which Pavey-Smith[3] has called attention, is redness limited to the tonsil and its immediate surroundings, and especially a vertical red streak about one-eighth of an inch wide running the whole length of the anterior pillar. Lott[4] has also described and Chevalier Jackson illustrated a similar sign. It consists of a narrow, sharply limited and very dark red zone on the anterior pillar in front of the tonsil. Lott regards it as an important distinguishing feature of an infective tonsillar focus in which streptococci predominate. In Lott's experience when a tonsillar focus of this nature is present tonsillectomy will yield good results in arthritis, neuritis, &c.—I am, Sir, yours faithfully,

W. S. THACKER-NEVILLE,

THE TREATMENT OF ULCERATIVE COLITIS.

To the Editor of THE LANCET.

SIR,—The discussion on ulcerative colitis at the Harveian Society[5] did not evince nearly so pessimistic a view of the results of treatment, medical or surgical, as correspondents have assumed. The appearance of pessimism is probably due to a very grave series of figures quoted by one speaker. The results which I gave personally when opening the discussion are as follows: Among 15 private patients since the war 2 have died; both these finally died in hospital. These are the only deaths which I have had in hospital and there have been 10 other hospital patients, a total of 2 deaths among 25 patients. None of these cases was treated surgically. May I repeat the opinion expressed in the discussion that there is no justification for the appalling mortalities recorded?

One often reads such statements as "medical treatment was tried and failed." The question, of course, arises as to what was the medical treatment adopted. As it is laid down in the literature and actually applied in practice, medical treatment not uncommonly resolves itself into a combination of opium, starvation, and medicated enemata, a course of treatment which would produce ulcerative colitis in most healthy persons. I am not here criticising surgical treatment—that is appendicostomy—as described by Mr. Norbury at the Harveian Society discussion, and by Mr. Lockhart-Mummery in your columns. It is a valuable and rational procedure though, I believe, unnecessary. But a protest is needed against what is described and employed as "medical treatment." There is at present in the wards at St. Thomas's a girl who illustrates what can be done in a very severe case by the methods I described at the Harveian Society. On commencing treatment her weight was 52 lb., and she had been losing ground rapidly. She now weighs over 8 st. I would like also to mention the question of diet which I did not refer to at any length during the discussion at the Harveian Society. I agree with everything which Mr. Lockhart-Mummery has said in his letter as to the importance and possibility of giving a considerable diet. It is pitiful to recognise that cases of ulcerative colitis are often starved not by the diarrhœa but by unnecessary deprivation of food.

I cannot comment on the favourable results of serum treatment which Dr. Hurst and Dr. Ryle have obtained. This has, unfortunately, not been the experience of myself and many others. But I am certain that neither of these experienced physicians have followed the crudities of what is usually described as the "medical treatment of ulcerative colitis."

I am, Sir, yours faithfully,

H. LETHEBY TIDY.

TUBERCULOSIS AND EMPLOYMENT.

To the Editor of THE LANCET.

SIR,—Medical men who have to deal with larg numbers of employees must often be, as I frequentl am, in considerable difficulty in deciding the importan question: how far they are justified in sending bac to sedentary occupations officials and employees wh have tuberculous disease of the lungs, where th lesions are still unhealed. It is generally assume rightly or wrongly, that in phthisis, where tuberc bacilli are not found in the expectoration, it is sa to send the patient back to work under ordinar office conditions. This may, or may not be wise, bu it is a line of conduct which I think most of us follow The class of case which gives me anxiety, and whic must be a source of uncertainty to others, is whe there is an unhealed tuberculous lesion of the lun with tubercle bacilli still present. In these cases the is often a very considerable increase of weight, th patient looks well, his cough is slight, he has minimum amount of expectoration, *but* the tuberc bacilli are still present. Frankly I find a prop decision in this class of case an exceedingly difficu one, having in mind the conditions under which wo must necessarily be carried on. It would be inte esting to know what the view of the Ministry of Healt is. So far it seems to have remained discreetly silen and I fear the only answer we shall ever get is th "it depends on circumstances"—and this does n take us any further.

I am, Sir, yours faithfully,

JOHN COLLIE.

Porchester-terrace, W., April 27th, 1928.

CONDITIONED REFLEXES IN ASTHMA.

To the Editor of THE LANCET.

SIR,—When demonstrating the wide applications Pavlov's work in a leading article last week you p forward an asthma theory which has been so oft advocated by psychologists that I should like—on more—to give a fraction of the case against it.

No one can doubt the great part played by psych logical reflexes in producing the asthma syndrom It is perfectly true that—to take hay-fever for o example—a hay-fever patient develops what I ta to be a conditioned reflex from, say, the sight of sunny hayfield; he may even develop such a refl from the sight of a rose made of wax if he happens think that his trouble derives from roses. This do not explain how he can infallibly (and at any tir of the year) pick out by a skin reaction a wate extract of grass pollen from a dozen other unkno fluids. The observer may make him expect that o of the other fluids will give the specific reaction, b his skin is not deceived. A worse difficulty for th who believe that a primary emotional stimul provokes the disease is the Prausnitz-Küstner reactio These workers found that the liability to the dise may be transferred to a normal individual (or to part of him) by injecting into him serum taken fr a patient who is liable to an attack. It is difficult see how one could transfer the liability to a condition reflex in this way.

I am, Sir, yours faithfully,

Devonshire-place, W., May 21st, 1928. J. FREEMAN.

IMPORTATION OF YATREN.—Representations ha been made to the Board of Trade that yatren (iodo o quinoline sulphonic acid) should be exempted from d under the Safeguarding of Industries Act (1921) on grounds that it is not made in any part of His Majest Dominions in quantities which are substantial hav regard to its present consumption in the United Kingd and that there is no reasonable probability that it within a reasonable period be made in His Majest Dominions in such quantities. Communications concern these representations may be addressed to the Princi Assistant Secretary, Industries and Manufactures Dep ment, Board of Trade, Great George-street, London, S.W before June 15th.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

National Health Insurance Bill.

Experimental Clinics.

On Clause 14,* which deals with surplus funds of approved societies, Mr. Rhys Davies moved in Subsection (3) to leave out para. (7). He said that he understood the Minister of Health and the Parliamentary Secretary to say on the second reading of the Bill that it was the intention to set up experimental clinics in respect of dental and ophthalmic treatment. He took it that the whole country could not be covered with clinics, and that when a clinic was set up in a particular town, the insured person could not be compelled to attend it. If they compelled him they took away his freedom of choice. He would like the Minister to make it perfectly clear that there would be freedom of choice. This was one of the most important clauses in the Bill. The two professions, the dental and the optical, fell into different categories. The dental profession had definitely secured their status. The antagonism between them and the British Medical Association was not as great as the antagonism between the medical profession and the people who practised optics. An approved society at the present time did not compel an insured person to go to an ophthalmic surgeon but some approved societies would pay the expenses of an ophthalmic surgeon, who would give the patient a prescription to take to the optician who provided the glasses. The ideal would be to send every insured person to a qualified medical man who had specialised in eye diseases, and for his prescription to be made up by an optician, but as a member of the Departmental Committee which had enquired into the registration of optical practitioners, he was satisfied that many of them would be dead before that ideal stage was reached. Did the Minister intend to lay down by regulation that all insured persons must in the first place be sent to a specialist in eye diseases to obtain a prescription and then take it to an optician, or did he propose to have the dual method of treating these people by allowing the two systems to continue?

Dr. Vernon Davies said that the majority of general practitioners had no interest in the examination of eyes or spectacles. The British Medical Association stated that there were in this country about 1000 doctors who were experts in ophthalmology, and who were prepared to work under the scheme. The hon. Member said that perhaps this number was not enough. What he (Dr. Davies) suggested was that the British Medical Association and the profession generally should be given a change. If they undertook to do this work it should be the duty of the Minister to accept their offer to run the scheme.

Mr. Chamberlain said that he had already given a definite pledge in the House of Commons that a free choice must remain a cardinal feature of any scheme that was introduced. He was prepared to accept an amendment which would place the point beyond all doubt. It was an amendment standing in the name of Mr. Whiteley which would be moved at a subsequent stage. He was quite prepared that the normal course which he would pursue was that if he found it necessary to enter into arrangements through his Department without the assistance of representatives of other bodies, before coming to a final conclusion with any of the professional bodies with whom he might be negotiating, he would submit the proposed terms to the Consultative Council so that the views of the societies as a whole could be stated. He certainly did not intend to authorise the setting up of a dental clinic by an approved society managed solely by that society. These experimental clinics were to be experimental and managed by a joint body representing both the professional classes and the representatives of approved societies. He thought the Committee fully appreciated the difficulties in connexion with the question of the opticians and the ophthalmologists. They had a large number of cases of eye defects which were due to some mechanical fault in the construction of the eye, and all that was required to put them right was to fix a glass suitable to correct the mechanical fault. On the other hand, there were other defects of sight not caused by mechanical alterations or faults in the construction of the eye, but were caused by disease. He was advised that it was not always a simple matter to decide whether the trouble from which the patient was suffering was due to disease or to a mechanical condition of the eye which might or might not have been caused by disease. If it had been brought about by disease it was a matter upon which skilled advice was necessary. What one obviously desired to obtain was that the insured person should have the opportunity of getting in every case such advice as would give him the treatment he required, or the correct mechanical appliance, if that were necessary. He did not think it was possible at that stage to lay down a general rule or regulation providing that every insured person who was suffering from an eye defect must go to an ophthalmic surgeon first. There was not always such a surgeon handy, and it was not the intention of the regulation to enforce a practice which he did not think could actually be carried out.

Lieut.-Colonel Fremantle said he had been asked by the representatives of the Dental Service Association, and also the British Dental Association, to bring this question forward. The Dental Association felt very strongly the danger that clinics might be set up and managed by approved societies and that they might get back to the old position which was certainly not in the interests of the insured person, under which medical and dental clubs were run by approved societies who made a profit out of the professional work, and did not give proper attention to medical considerations. That difficulty was met in general by the Insurance Act, and they did not want to get to that situation. He thought he might say for the medical profession generally that in this matter they would support the dental profession, and they were opposed to any such practices as those he had mentioned. The Minister had said that he was ready to provide that no clinic should be managed by an approved society. He (Lieut.-Colonel Fremantle) was not competent to give the opinion of the societies that had approached him, but they suggested that there were dangers if any body of persons set up a clinic, and they would naturally demand to have a voice in the management. They trusted to the Minister to see that regulations were made providing that the management must give fair weight to professional circumstances and considerations and should not unduly consider the financial side and strength of approved societies. He thought the Minister had made out a case for regulations which, speaking from a point of view of administration, they could not resist. He wished, however, that the procedure could be improved so as to give them greater facilities for supervising the regulations.

Colonel Sinclair said that notwithstanding the substantial concession which the Minister had given, particularly to the medical men, for which he was grateful, he had some anxiety about the sanctity of the free choice of dentist in respect of the dental clinics. The Act of 1921 required that dentists should be registered, and a very heavy annual fee was obtained from them not only for registration at the beginning, but also for renewal each year. One's sympathies went out to the struggling dentist, and he would like an assurance from the Minister on one point. In establishing the dental clinics under this Bill certain dentists would be selected to serve, and it seemed to him that those dentists would be placed in a favourable position as compared with outside dentists. They had had an assurance that there would be a free choice of dentists, but he would like to know how the competition between the dentists who were connected with the clinic and the outside struggling dentists would be maintained.

Mr. Chamberlain: I am afraid that I cannot give my hon. friend any further assurance than that I gave most definitely to the House.

Mr. Davies's amendment was, by leave, withdrawn.

Further Amendments.

The following amendment in the name of Mr. Whiteley was agreed to without discussion:—

In Subsection (3), new Subsection (7), at the end, to insert the words: "Provided that such Regulations shall not restrict the right on the part of any insured person to obtain treatment from any practitioner, clinic, or other institution with whom arrangements with respect to that form of treatment have been made in accordance with the Regulations."

Mr. Womersley moved the following amendment:—

In Subsection (3), new Subsection (7), after the words last inserted, to insert the words: "Provided that any Regulations made under the Act shall not restrict the right of any insured person to obtain ophthalmic treatment of an optical character from any optical practitioner who has been hitherto engaged in sight testing and the supply of optical appliances under the National Health Insurance Acts and whose qualifications may be regarded by the Minister of Health as providing a safeguard in these respects."

The amendment was negatived.

Mr. Briant moved:—

In Subsection (3), new Subsection (7), after the words last inserted, to insert the words: "Provided that no such Regulation shall provide for or authorise the establishment of a dental clinic by an approved society or the use of the funds of such society for the purpose of defraying the cost of the equipment for or maintenance of such clinic, nor shall such Regulation in any way specify the dentist or clinic or other institution from whom any insured person is to receive treatment or in any way

* The first part of the discussion on Clause 14 appeared in our issue of last week (p. 1047).

restrict the right of any insured person to select the dentist or clinic or other institution from whom such person wishes to receive treatment."

The amendment was negatived.

The Committee adjourned.

The National Health Insurance Bill was further considered by Standing Committee C of the House of Commons on May 8th. Sir R. SANDERS was in the chair.

Employment Within the Meaning of the Act.

On Clause 17 (which amends the principal Act as to employments within the meaning of the Act),

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) moved an amendment providing that the Minister of Health might make a special Order in cases where there was more than one owner of a fishing vessel, providing that a specified person should be deemed to be the employer for the purposes of the Act. He said the object of his amendment was to bring under the National Health Insurance scheme workers such as shore fishermen, who were at present excluded on the ground that they were not technically employed under contract.

After some discussion Sir Kingsley Wood's amendment was agreed to on his giving an undertaking that before his Department prepared the special Order, and considered who would have to make the contribution in respect of the employer, they would consult the local associations and other bodies on the subject.

New Clauses.

Sir KINGSLEY WOOD moved a new clause providing that regulations might be made requiring that in the case of investments arising out of business under the Act they should be transferred to the joint names of the Minister of Health and two or more of the trustees of an approved society; or, if the society so requested, to the name of the Minister alone.

The clause was agreed to, and added to the Bill.

Sir H. NIELD moved a new clause empowering insurance committees to make contributions to a fund to provide superannuation allowances or other benefits for their officers or servants.

Sir KINGSLEY WOOD accepted the clause, which he said was so drafted as to enable the Minister of Health to satisfy himself, with the advice of the Government actuary, that any scheme designed for the benefit of staffs of insurance committees was sound, and power was also given to them to review the operation of the scheme from time to time.

The clause was agreed to, and added to the Bill.

Maternity Benefit.

Dr. DRUMMOND SHIELS moved the following new clause :—

Subsection (1) of Section 14 of the principal Act shall have effect as if the following words were added at the end thereof: "in addition to treatment and attendance by a duly qualified medical practitioner or by a duly certified midwife."

He said the amount of maternity benefit provided by the principal Act was 40*s*., and the new clause would provide that this amount of benefit should be given in addition to treatment and attendance by a duly qualified medical practitioner or by a duly certified midwife. While the problem of maternal mortality was a very difficult one and included many factors, there was no doubt that the importance of adequate attendance at the time of birth, and for a certain time thereafter, was recognised as one of the most important elements in the problem. It was quite well known that the amount of money which was given for maternity benefit, and which had in a number of cases been increased beyond the sum mentioned in the Act, was not always expended for medical attendance or for the attendance of a midwife; and one could easily understand why that should be so. Whatever difficulties might be found in the working out of this clause they ought to be faced and surmounted. The country was very much concerned at the fact that while they had reduced ordinary mortality-rates very considerably, and were steadily and constantly reducing infantile mortality-rates, the mortality-rate for women in and immediately after childbirth had practically remained stationary for the last 100 years. As a partial attempt, at any rate, to solve this problem, he thought the committee would do well to accept this clause.

Sir KINGSLEY WOOD said he thought the whole committee would be quite sympathetic with the object which Dr. Shiels had in view. The Minister of Health was very much interested in, and concerned with, the question of maternal mortality. The committee would be well aware of the steps which his Department were taking to get more light upon that difficult problem. But he could not advise the committee to accept this amendment for two reasons. The first was the purely technical one, that if Dr. Shiels wanted to deal with the provision in relation to maternity benefit, he ought to do so under Section 10 of the original Act. But the real reason was that this amendment, if it were adopted, would cost the National Insurance scheme an additional £1,500,000 a year. Dr. Shiels did not tell them where he was going to get this money from. It was obviously impossible at this stage of the Bill to accept an amendment of this kind, which would seriously upset the finances of the whole scheme, and put the approved societies under great difficulties.

Lieut.-Colonel FREMANTLE said he was glad to hear from Sir Kingsley Wood that there was no dispute as regards the serious question which was raised here, and the necessity for facing it. It was a matter to which he hoped the approved societies would turn their attention. He was afraid that approved societies did not always look at matters from the same point of view as he did.

Mr. RHYS DAVIES: As the medical profession do!

Lieut.-Colonel FREMANTLE said those societies were very often concerned with the financial needs of their members instead of with their medical needs. They had, however, to face the fact that, as Sir Kingsley Wood had pointed out, they could not raise the £1,500,000 necessary under this amendment, but he wished again to enforce what he hoped was the general sense of the committee and of the House—namely, that it was necessary to meet the very serious needs which had been referred to, and he was very glad that the Parliamentary Secretary had expressed his official sympathy with that object.

Dr. SHIELS said he quite recognised that at present according to the system and arrangement of the scheme there was no money available, but it was quite obvious from reading the report of the Royal Commission that money could be obtained if certain arrangements were made. He was very anxious that approved societies, as well as some others, should take this matter into very serious consideration, and should be willing to agree to certain arrangements which might make what he had suggested possible. The first consideration under the Act was to give an adequate medical service, and he certainly thought that medical and midwifery attendance, which was recognised to be of first importance, should be a statutory benefit. He had put this amendment forward to emphasise that view, and having done so he would ask leave to withdraw the clause.

The clause was by leave withdrawn.

Dental and Ophthalmic Treatment.

Mr. RHYS DAVIES moved a new clause providing that dental and ophthalmic treatment should be included in the list of statutory benefits under the Bill.

Sir KINGSLEY WOOD said that a complete dental service which they all agreed would be eminently desirable, would cost about £4,500,000 a year, and would add to the contributions in connexion with national insurance about 1½*d*. a week. Obviously this amendment must fall to the ground because there was no financial provision to meet such a charge. While they could understand a member of the medical profession not paying much regard to where the money was coming from, they did expect a little more from Mr. Rhys Davies.

Lieut.-Colonel FREMANTLE: I must protest against that remark about the medical profession.

Mr. RHYS DAVIES asked leave to withdraw the clause. The clause was by leave withdrawn.

Other Amendments.

Mr. RHYS DAVIES moved a new clause empowering an approved society with branches on a two-thirds vote to contribute a proportion not exceeding one-third of the distributable surpluses of the branches to the creation of a central fund which would provide the members with specified minimum of additional benefits.

Sir KINGSLEY WOOD opposed the new clause on the grounds that the societies were themselves divided upon the proposal, that the Royal Commission had made no recommendation on it, and that the Consultative Committee had also made no suggestion with regard to it.

The amendment was defeated by 21 votes to 11.

Dr. WATTS moved a new clause providing payment for X ray examinations in cases of fracture or suspected fracture where such examination was recommended by the insurance practitioner.

Sir KINGSLEY WOOD said he hoped Dr. Watts would not press this amendment, which, though it might be desirable, would mean increased cost.

The clause was negatived.

Dr. SHIELS moved an amendment to the first schedule of the Bill (which is to be substituted for the third schedule to the principal Act). The amendment proposed to add at the end of paragraph 1 the words "in the case either of all members of the society or of such of them as have any children or any specified number of children wholly or in part dependent upon them." He said the schedule dealt with the additional benefits which were allowed to be given. There were some additions, but there were at least two items which were left out, and which were in the original

Act. The effect of the amendment would really be to replace paragraph 1 as it originally stood. The principle of dependent's allowances had been admitted by the Unemployment Insurance Act, and it was agreed that it worked equitably, and gave a fairer distribution of the money available than a flat rate to the recipients quite independent of the burdens or dependents which they had. Therefore he did not consider it desirable or wise to drop altogether from the schedule, what was regarded by the Royal Commission as a very important item, and he did not quite see why it was done.

Sir KINGSLEY WOOD said this provision had been deleted from the scheme, not at the instance of the Ministry of Health, but on the direct recommendation of the Royal Commission. If they were going to have a scheme of allowances to dependent children they should not allow a society here and there to put into operation a scheme of this kind, which was very unfair to other societies, but they should do it as a general scheme under the Act.

The amendment was rejected by 17 votes to 8.

The committee adjourned.

Additional Benefits.

The committee further considered the Bill on May 10th. Sir R. SANDERS was in the chair.

On the First Schedule (which deals with additional benefits),

Lieut.-Colonel FREMANTLE moved to insert after paragraph 7 the following new paragraph: "The payment of the whole or any part of the cost of medical or surgical advice or treatment by any registered medical practitioner, not being advice or treatment within the scope of any other additional benefit or of medical benefit, under a special scheme approved by the Minister for the purpose." He said this new paragraph was passed unanimously at a meeting of the Parliamentary Medical Committee last week, and he thought it represented the general opinion of the medical profession. They wanted to extend the Insurance Act as far as possible by degrees where required, supplementing it where possible by skilled advice. They all knew the limitations of the Act, but they also recognised that there were great advantages in having expert advice from time to time in various forms. First of all it took the form of surgical operations or advice by surgeons, who from the nature of their work, and their eminence, could not be retained permanently as part of the panel system. Secondly, it required skilled consultation, which would often save a very great deal of sickness, and therefore would be an economical proposal in order to give real assistance to panel practitioners. In the third place it included special treatment, such as X ray treatment and other specialties. From the medical point of view he objected to the first seven places in the Schedule being taken up by what were really cash benefits. Medical men looked upon the insurance scheme as one for prevention and treatment, and on cash benefits as being only secondary to that. Therefore, though he should prefer to see this new paragraph at the top of the schedule, he moved it as No. 8 in order that it might take priority of the other additional benefits which more or less corresponded to some form of medical treatment. This proposal was economical, elastic, and optional; and he thought it should meet with general support.

Dr. SHIELS, in supporting the amendment, said he regarded it as a very unsatisfactory substitute for the provisions made in line with the recommendations of the Royal Commission as part of the statutory benefits. The Royal Commission recommended this as the very first necessary change to provide an adequate service. At present they had a scheme which was called the National Health Scheme, which was incomplete, and left out at the most important time the services to insured persons of a specialist, who might be able by early intervention to prevent very serious happenings. However, as a second best it was important that this should go in under the heading of possible additional benefits. The health side of the National Insurance scheme had not been so prominent, or so much emphasised, as it ought to have been. He hoped the Government would accept the amendment.

Mr. MELLER said he would have been very kindly disposed towards the amendment if there had been a proper realisation of what the schedule really meant. Dr. Shiels imagined that the recommendations of the Royal Commission included one that specialist service should be extended to additional benefits. As a matter of fact, the Commission recommended that there should be an extension of the medical service as a statutory benefit as and when the money was available. What was happening to-day in regard to additional benefits in the nature of medical benefits was that the medical profession and the hospitals as well were saying to the people who were in the habit of going to a hospital for extended service, which could not be given by the panel practitioner, that if their society was providing dental and ophthalmic treatment the help originally given by the voluntary hospitals must be cut off. If this proposal were accepted within the scope of additional benefits he was afraid that there would be more pressure put by the medical profession on insured persons to get their societies to devote a proportion of their surplus funds for the provision of this benefit. He agreed that this would be for the benefit of the insured persons, but incidentally and materially it would also be for the benefit of the medical practitioners. What the Royal Commission said was: "We realise the necessity for extended medical service," and putting it in the order in which they recommended these things, they said "as soon as possible and as soon as the societies have funds let us have this extended and complete system of service as a statutory benefit." They were not dealing that day with it as a statutory benefit, and therefore he thought the committee ought not to consider it.

Mr. RHYS DAVIES said if this proposal were adopted, the ordinary patient would go to his panel doctor, who might say to him that the disease from which he was suffering could not be treated by him as a panel practitioner. The patient would have to come to the doctor in another category. The panel doctor might say to the patient: "You require specialist service, and you must ask me to give you specialist treatment, and I can get paid for that under this new provision." They already had 16 additional benefits, not more than half a dozen of which had ever been adopted. What was the use of deceiving the insured population by pretending they were going to do something they knew full well could not be done?

Mr. CHAMBERLAIN (Minister of Health) said he agreed with Mr. Davies that it was a mistake to add benefits which were not likely to be used to the number of benefits already existing, thereby encouraging competition among the societies. But when the hon. Member went on to argue against the provision of a specialist service as an additional benefit on the ground that it was going to lead to the exploitation of the insured person by the medical practitioner, he would point out to him that that argument would apply just as much to the provision of the specialist service as a statutory benefit as to its provision as an additional benefit.

Mr. RHYS DAVIES: I agree.

Mr. CHAMBERLAIN said that Mr. Davies, therefore, was arguing against the provision of a specialist service at all. There he came into conflict, not only with Dr. Shiels, but with the Royal Commission, who decided that the advantages and benefits to the insured population of having recourse to specialists outweighed all the disadvantages. It was only the fact that the method of providing these services recommended by the Royal Commission was so strongly objected to by the approved societies themselves that prevented specialist service becoming a statutory benefit. A panel doctor could not pose as a specialist and extract fees from his patients as a specialist unless first of all he satisfied his insurance committee on two things—that the particular complaint he was treating was beyond the competence of an ordinary general practitioner to treat, and that he himself possessed the competence as a specialist to treat it. He (Mr. Chamberlain) thought that ought to be a safeguard against any general malpractice such as had been suggested.

Mr. RHYS DAVIES: Has the right hon. gentleman's Department ever been able to say where the dividing line comes in between specialist treatment and the ordinary medical practitioner's work?

Mr. CHAMBERLAIN: I am told that there are dozens of decisions.

Mr. RHYS DAVIES: That makes my case all the stronger.

Mr. CHAMBERLAIN said that he would tell the committee the argument which finally decided him in favour of the amendment. In paragraph 15 of the Schedule one of the additional benefits already provided was:—

> "Payments to approved charitable institutions in respect of any treatment of members required for the prevention or cure of disease, not being treatment within the scope of any other additional benefit or of medical benefit."

That meant that a society could select as an additional benefit specialist treatment in an approved charitable institution. It had been argued that that was weighing the balance unfairly against treatment by the private practitioner, and that if they said that specialist services might be provided in institutions they ought at least to give the society the opportunity of getting those same specialist services through private practitioners if they preferred it. He thought that there was something in that argument. The acceptance of Lieut.-Colonel Fremantle's amendment would remove any stigma of preferential treatment in this matter; it would make a fair distribution. Societies were not obliged to adopt this particular benefit, and if it was not adopted it could be removed from the list at some future date.

The amendment was agreed to.

Lieut.-Colonel FREMANTLE moved to insert in the First Schedule after the words agreed to. the following new paragraph: "The payment of the whole or part of the services of a midwife or medical practitioner in cases of confinement." He said that he was sorry that on the previous amendment he gave Mr. Rhys Davies the impression that he was putting forward something in the name of the medical profession in their own interests. He entirely dissociated himself from that idea. They were dealing with this matter from the point of view of the public service. They knew the very difficult cases which midwives had to deal with and how they were accountable, among other causes, for the terrible maternal mortality which was one of the chief things which the health system of this country had to deal with. Statutory maternity benefit was cash benefit, and the result was that in many cases the maternity benefit was eaten up by other necessities and proper provision was not made for the attendance of a midwife or a medical man. He put in the words "or general practitioner" in order to include all cases, but he asked that approved societies might be allowed, as was the case now in some societies operating in rural areas, to provide for the services of the midwife herself in addition to the payment of the standard cash benefit.

Sir KINGSLEY WOOD said that standard maternity benefit was 40*s*., but a very large number of societies had increased it, and the average amount paid was about 46*s*. There had been a tendency from the first for the whole of the sum paid by way of maternity benefit to be demanded as a fee by the doctor attending the confinement and as the amount had increased from 30*s*. to 40*s*., and later to an average of 46*s*., so the doctor's fee had shown a tendency to increase pari passu. He agreed, however, that there was a good deal to be said for a reconsideration of the methods by which they dealt with this matter under national health insurance. At the present time a subcommittee of the Consultative Council were considering it to see whether any recommendations could be made and whether any agreement could be obtained. In the meantime he did not think it was desirable to include in the list of medical benefits an item of this character.

Dr. SHIELS said he thought that Sir Kingsley Wood had very adroitly taken advantage of the prejudice of certain hon. Members against the medical profession. Everyone was agreed that the Ministry of Health were very much interested in this subject and had shown great sympathy towards any possible solution of the difficulty of maternal mortality. Amid all the proposals to deal with that grave problem the provision of adequate midwifery was absolutely essential. It was true that in considering this matter the Royal Commission pointed out that it ought to be linked up with some national scheme, especially in relation to local authorities. He would be prepared to delete the words "or medical practitioner," and he would be glad if the Government would agree to that.

Sir KINGSLEY WOOD: No, I think we had better await the report of the expert committee.

The amendment was negatived.

Lieut.-Colonel FREMANTLE moved to include in the list of additional benefits medical treatment or attendance for any person dependent upon the labour of a member.

Sir KINGSLEY WOOD said that it would be absolutely impossible for approved societies to-day to attempt to give by way of additional benefits medical attendance to the dependents of insured persons.

Dr. SHIELS said that the object of the amendment would be served if it pointed out once again that this was not really a National Health Insurance scheme at all; it left out the dependents of the insured person and established unequal health standards in the community.

The amendment was negatived.

Dr. VERNON DAVIES moved an amendment to include in the schedule of additional benefits payments to women in the last weeks of pregnancy who had to leave their employment on account of that condition.

Mr. CHAMBERLAIN said that the amendment was very vaguely worded and he could not recommend the committee to accept it.

On a division 17 voted for the amendment and 17 against. The Chairman gave his casting vote against the amendment, which was accordingly rejected.

The Committee stage was concluded and the Bill as amended was ordered to be reported to the House.

MINISTRY OF HEALTH VOTE.

On Tuesday, May 15th, the House of Commons went into Committee of Supply on a vote of £13,774,025 for the salaries and expenses of the Ministry of Health. Mr. JAMES HOPE, Chairman of Committees, was in the chair.

In the course of the discussion which followed the speech of Mr. CHAMBERLAIN, Minister of Health, reported in last week's issue of THE LANCET (p. 1048),

Mr. BRIANT said he could not share the optimism of the Minister in regard to

The Housing Problem.

At present there were 3,000,000 people living in overcrowded and insanitary conditions, and the present rate of progress was too moderate; facts were not faced. They had to support hundreds and thousands of men and women because they were broken down owing to bad housing conditions, and money spent would be economy.

Mr. A. GREENWOOD said that in so far as the Minister of Health was making new and special efforts to deal with maternal mortality, rheumatism, and other great problems of public health, he would have the support of the Labour Party. The solution of the difficult slum problem depended in the first instance on an increasing supply of new houses. The housing functions of the Ministry of Health were becoming mechanised and old fervour was being dissipated. A jog-trot production would not sufficiently deal with the whole housing situation. In reference to the administration of the poor-law, instead of looking forward the Minister was looking backward to 1834 and trying to drive boards of guardians into a perfectly inhuman administration of the poor-law system. When the Minister was speaking about maternal mortality and the horrors of the slums, he was pitying the very people who were being dealt with so harshly to-day under the present methods of administering the poor-law and the treatment of the unemployed.

Lord H. CAVENDISH-BENTINCK entered a protest against the policy of reconditioning. Many of the houses which it was proposed to recondition ought to be pulled down. He wished to plead for concerted action on behalf of the enormous army of casuals in this country. The Metropolitan Asylums Board was showing the way to a more intelligent policy in regard to the classification of applicants for relief. The Ministry of Health, either by law or by persuasion, should get statutory committees appointed in every county all over the country so that there might be a coördinated policy with regard to the people who drifted from one place to another.

Mrs. RUNCIMAN said that in one of the big industrial towns recently the medical officer of health reported that in the case of 1000 confinements in the district in only 284 cases was a separate room available. In 12 cases four other persons had to share the same room, and in another case five, while in yet another case even eight persons had no other accommodation. Over 400 of these houses were shared by two or more families.

Lieut.-Colonel FREMANTLE said he thought rather an exaggerated idea was being given of the lack of houses that still remained. On the figures of the two censuses of 1911 and 1921 there was a definite shortage in 1921 of 304,000 houses in England and Wales. Since then it had been reckoned that allowing one house per family they required an increase every year of, roughly, 72,000 houses. Taking into account the necessary replacements of old houses, the actual requirements every year were about 120,000 houses and that was a generous estimate. At the rate of 120,000 since 1921 that meant that they had a further need of 840,000 houses in England and Wales. If they added to that the shortage in 1921 census of 304,000 it meant that at the present moment they had a shortage of 1,144,450 houses against the number of houses that had been built. The number of houses built since the Armistice was over 1,100,000; in other words, their shortage was actually, on the 1911 basis, only about 40,000 houses. They were making up that shortage slowly. In the greater part of England they would have reached by the middle of next year, if not by the end of this year, a position which would be above the basis of the 1911 census. What they wanted was a comprehensive scheme dealing with slum clearance by means of new legislation, but he did not think the overcrowding was getting worse.

Compulsory Vaccination.

Mr. GEORGE THORNE said that the whole House would be with the Government in whatever movement they could make, and in whatever money they proposed to spend, to get rid of slum dwellings and to give the children of the country a better chance.

Dr. WATTS thought that the time was fast approaching when the Ministry should be reorganised. It should have taken from it services such as housing, rent restriction, rating and valuation, and the control of boards of guardians except so far as that control related to medical attendance on poor people. Most of these duties, for example, he thought might be transferred to the Home Office, while the Ministry of Health might take over from that office the medical service in connexion with the Factory Acts. He went on to criticise the expenditure incurred upon tuberculosis sanatoria with incommensurate results, and to speak of the difficult position in regard to vaccination. He said that he did not complain of conscientious objection and he was not suggesting that that provision should be done away with

hough personally he thought it should. But for some time ast a great number of people had not only not had their ildren vaccinated, but they had not taken the trouble to ake a conscientious objection. The result was that the w in that respect was practically a dead letter.

Mr. GROVES: Thank goodness!

Dr. WATTS said that Mr. Groves might say that, but he ad probably never experienced an epidemic of small-pox. such an epidemic broke out in his neighbourhood probably e first thing he would do would be to rush off to be accinated.

Hon. Members: No.

Dr. WATTS said he had known conscientious objectors ho had willingly submitted to having a child vaccinated ther than that the child should be prevented from going America. He wanted to point this out to the Minister the hope that something might be done, because those who ew small-pox, and were acquainted with its history, alised that previous epidemics had always been preceded sporadic outbreaks of a wild character; after a number which a virulent epidemic had suddenly burst forth, rrying away thousands of people and crippling and blinding ousands of others.

Mr. GROVES: Does the hon. Member know that they ve abolished it in Holland?

Dr. WATTS said that Holland carried out vaccination ore efficiently than we did in this country, and quoted razil as an example of a country where vaccination was gidly insisted upon. He hoped the Government would ve the Committee some assurance that they intended in e future to carry out both in the letter and the spirit the esent Vaccination Act.

The Case of Mary Race.

Mr. LAWSON raised the case of a child named Mary Race o had died in a diphtheria hospital in circumstances ich he had stated to the Minister of Health necessitated public inquiry. He had received a letter from the Minister the course of which he said that there was no reason to lieve that the child's death was brought about or celerated by lack of nourishment, but he suggested that e officer of the Ministry had made only a perfunctory quiry and did not interview a deputation which had been pointed.

Dr. VERNON DAVIES said that Mr. Lawson had presented one-sided tale. The child was in hospital for six days fore she died, and probably had received the serum and esumably had had a certain amount of nourishment during e six days. It was a very serious statement to make in e House that the Minister of Health was prepared to send responsible medical officer to make an inquiry into a case d that the medical officer had practically perjured himself the purpose of bolstering up the Ministry of Health. e Committee should not forget that the deputation nsisted of people who were ex-guardians who had been rned out of their job for maladministration, and that erefore they were not particularly well disposed towards e Ministry of Health. Speaking of the Minister's speech on the vote, Dr. Davies said that the whole Committee ould recognise that the Minister could only cover a small rt of the ground for which he was responsible, and there re one or two points to which he (Dr. Davies) would like refer.

Cancer.

The Minister of Health had spoken about cancer and the ogress that had been made in the ancillary treatment of at disease, referring particularly to radium treatment, eming to give the impression that the Ministry was anxious help the radiologists to deal with cancer and that they re very hopeful regarding the results. He (Dr. Davies) nted to impress upon the Committee and upon the country at the only safe thing for cancer was early and complete eration. Unfortunately it occasionally happened that ey got cases which were late and inoperable and then haps radium treatment might prolong the life of the tient, or perhaps give him a little more ease; but atever they did they should not get into their heads the a that radium would cure cancer; it could not do it at e present time. It was only a help, and he was afraid at the rather hopeful tone of the Minister of Health might ate a wrong impression in the country and prevent some those poor people from seeking medical advice in the ly stages when something could be done. He was glad at the Minister had dealt with the question of rheumatism, t all who had read the address of the Chief Medical Officer the Ministry of Health at the recent conference at Bath [1] uld have gathered that the Ministry itself was not acting the advice given by its well-informed medical department. e Minister said that there were 400 to 500 beds in the ntry earmarked for the treatment of rheumatism in ldren. That number was almost ludicrous when they realised the number of the sufferers and that with young children the large majority who got rheumatic fever or acute rheumatism developed heart disease.

Maternal Mortality: The Milk-supply.

Turning to the question of maternal mortality Dr. Davies said that the Minister was fully alive to the importance of that subject, but he was not sure that they were using the material which they had at hand to the best advantage. They heard of a shortage of midwives, but it must be borne in mind that the midwife's life was a hard and difficult one and poorly paid. Yet he had known many cases where midwives who were thoroughly trained could not get a sufficient amount of work for the reason that the better-class patients now went to nursing homes and the poorer-class patients went to poor-law hospitals. That was a point which the Minister would have to bear in mind, especially if he was going to increase the number of midwives. Another question which he wished to bring before the Committee was that of milk. A great campaign was going on in the country by which everyone was advised to drink more milk. People were being reminded that milk was a perfect food, that it was rich in vitamins, and that it was the only suitable nourishment for young children or suckling babies; it was also a very useful food for adults and they were doing all they could to see that this country produced good pure milk at a cheap price. This food was so valuable that it had been called one of the "protective" foods, the other being green vegetables, because it did not matter how unsuitable or peculiar the diet of an individual might be provided he included milk and green vegetables in his diet he would not go far wrong. The use of milk as a food was limited to some extent by its price. As a rule ordinary pure milk was too expensive for people living in very poor districts, and they had tinned or condensed milk of which such a large quantity was imported into this country, and the Minister of Health was perfectly satisfied that he was doing his duty to the babies of the country by labelling that milk "unfit for babies," though he knew very well that it was given to babies solely on account of its cheapness. It was essential that the Minister should see that the campaign for the production of pure and cheap milk should be brought to a successful conclusion. Unfortunately milk was very readily adulterated. The report of the Ministry on this subject had been drawn up carelessly. In the figures of percentages mistakes were by no means uncommon. The Committee would be surprised to learn that an examination of the records of the last three years showed that in 50 per cent. of the counties of England there was adulteration in more than 10 per cent. of the samples of milk examined in 1925. In Wales there was adulteration in 69·2 per cent. of the samples. It was a disgrace that there should be in the Ministry of Health a record showing that in one county in Wales 100 per cent. of the samples of milk examined were adulterated and that in the succeeding year not a single sample should have been analysed and that an explanation of this state of affairs should be forthcoming. The administration of the Act dealing with adulteration operated in such a way as to save the purchasers' pockets and was not regarded from the point of view of health. That was a great mistake. The administration of the Sale of Food and Drugs Act with regard to foodstuffs and milk should be taken out of the hands of the police and put into the hands of the local health authority. He urged that the Minister of Health should pay special attention next year to the defects which undoubtedly had existed in the administration of this Act in order to see if he could not get for the poor people a good, clean, healthy, and unadulterated milk-supply.

Birth Control.

Sir BASIL PETO said that there was no question that unreasonably frequent births under miserable conditions must be a contributory cause of maternal mortality. Deaths due to attempted abortion was also a material contributory cause of that mortality. He believed that there was another question which had a very close bearing on it, and that was the prevalence of venereal disease. On the main question of the undue frequency of births, he took to the Minister in July, 1925, a deputation of Members of the House of Commons to ask that the very restrictive regulations with regard to welfare centres and antenatal centres should be relaxed, their object being that the medical officer in charge should have unfettered discretion to give or to withhold, according to the medical condition of the case before him, information with regard to birth control. Within a couple of days the Minister told him that he proposed to modify the Regulations and gave him a copy. The second part of the formula as it now read was as follows:—

"It is not the function of an antenatal centre to give advice in regard to birth control, and exceptional cases where the avoidance of pregnancy seems desirable on medical grounds should be referred for particular advice to a private practitioner or a hospital."

[1] THE LANCET, May 12th, p. 981.

That was, then, to be altered in this way:—

"Where, however, in any particular case the avoidance of future pregnancy seems desirable on medical grounds, it is open to the medical officer of the centre, if he or she thinks it necessary, to explain to the mother how and where the appropriate information or advice can be obtained."

He (Sir B. Peto) did not, nor did the other hon. Members who were interested in the question, regard that as satisfactory. He could not see why, if it was left to the discretion of the medical officer, male or female, to deal with such a question, he should be instructed practically to withhold the advice, but to send the patient somewhere else to a wholly unsuitable place—namely, one of the general hospitals or to a special medical adviser, which in the case of a poor woman was really derisory advice, and advice which she could not follow. No alteration whatever was made in the regulations. In April, 1926, the question was raised in the House of Lords by Lord Buckmaster, and the resolution then moved was passed in spite of the opposition of the Government by 57 votes to 44. He hoped that the Government would not tell the Committee that there was no restraint put upon these doctors, for it was clearly understood that if the doctors sent their patients to get information elsewhere there was a great risk of the Government assistance to these clinics being withheld. Passing to venereal disease, he said that the Ministry of Health confined itself to dealing with the disease after it had taken hold, and refused to apply any preventive measures or allow the civil population access to preventive measures. In both the Army and Navy admirable results had followed from preventive measures. He wanted to know whether the Minister could say now, as was said by the Minister in 1925, in answer to a deputation of the combined societies—the Social Hygiene Council and the Society for the Prevention of Venereal Disease—that the recommendation of the report, now six years old, should be given effect to. He (Sir B. Peto) urged that it was not reasonable or right to allow the policy of the Ministry of Health to be governed purely by the opinion of one religious sect or another.

Mr. PETHICK-LAWRENCE asked what steps the Government had taken already to classify the maternity death-rate. The question of birth control was a difficult and delicate one. But he was convinced that they could not found morality upon ignorance. Any attempt to do so in the twentieth century was foredoomed to failure. Women belonging to one class already had that knowledge, and he was quite certain that if the information was not given to women scientifically and reverently by those who were the officers of the State they would obtain it in other ways less correct, and very likely much more injurious. When that undesirable form of information had been disseminated among women it would be very difficult to eradicate it. The Ministry of Health would be making a grave mistake if they did not see that the time had come to reconsider their original decision.

Mr. BLUNDELL said that there was not the slightest shadow of evidence that the failure of maternal mortality figures to diminish had been due to the failure of the maternity and child welfare clinics to give information about birth control. He wondered if the supporters of birth control had read the report of the medical officer of health for Birmingham for 1926. If they had done so, although that gentleman was himself a professed advocate of birth control, he (Mr. Blundell) thought that they would get information there which would cause them to have doubts before they advocated the teaching of these practices in public clinics.

Sir Kingsley Wood's Reply.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health), replying to the debate, said that he had some sympathy with the speech of Dr. Watts, and he felt that there was a good deal in what that hon. Member had said. He would point out that the total cost of poor-law administration in money and kind for last year was over £15,000,000 as compared with £5,750,000 in 1921. In the administration of such a large sum of money due care had been exercised and at the same time justice and fairness had been done to the people concerned. He was surprised that Mr. Lawson, who had held a ministerial position himself, should have thought fit to make such an attack on the bona fides and honesty of one of the inspectors of the Ministry of Health. That officer, and he believed the whole of the people concerned in the case which Mr. Lawson had raised, had no other wish than to ascertain the truth and report correctly and honestly to the Minister of Health. If Mr. Lawson would consult any medical Member of the House he would be told that no question of under-nourishment affected either the disease of diphtheria or the unfortunate death of the child which followed. Inquiries had been made since the matter was raised of both the father and aunt of the child, and it appeared that she was perfectly well nourished, and up to the day of the onset of her illness the relieving officer himself stated that he had never noticed any signs of malnutrition in any of the childre of this family, while a medical practitioner of long experienc who had known the child since birth was satisfied when h saw her on a material date that there was no sign of anythin of the kind. The Ministry of Health were fully satisfie that there was no foundation for the allegations. The matte raised by Sir B. Peto was a highly controversial and difficu one. The Minister of Health and his Department took th view that the present formula that was directed to th conduct of the maternity centres should be maintaine They would maintain that formula until the House Commons came to a contrary decision. It would be a greg pity if the excellent work of these centres, numbering ov 2000, which were attended by about a third of the mothe who gave birth to children, were involved in a controvers of this kind. In regard to the speeches made in the debat on the question of housing he (Sir K. Wood) thought if o could not be optimistic about what had been done i relation to housing in this country one must be a ver pessimistic person indeed. While the Ministry felt that th corner had been turned in regard to housing they did n consider that their work in that matter had ceased. The intended to go on with the housing programme and contin the considerable work which was being done by loc authorities in regard to the repair of houses.

HOUSE OF COMMONS.

TUESDAY, MAY 22ND.

Voluntary Hospitals and Motor Accidents.

Mr. LUNN asked the Minister of Health whether, i view of the great increase in cases caused by motor acciden which had to be dealt with by the hospitals, he would tak steps to call a conference between representatives of th voluntary hospitals, insurance companies, and other organis tions concerned, for the purpose of drafting a scheme t cover the expenses of the treatment of cases caused by mot accidents.—Sir KINGSLEY WOOD replied: My right ho friend must receive and consider the forthcoming fin report of the Voluntary Hospitals Commission befo deciding whether to take action on the lines which the ho Member suggests. (In reply to a previous question was stated that the report would be issued this month.)

The Services.

ROYAL NAVAL MEDICAL SERVICE.

A. R. Ewart and M. Clifford to be Surg. Lts.

Surg. Comdrs: C. M. R. Thatcher to Greenwich, continuation, and as Naval Health Officer and Medic Transport; F. C. Hunot to *Victory XI.*, for R.N. Hosp Portland; and G. D. Fergusson to *Maine;* J. S. Orw to *Royal Sovereign* (on recommg.); and G. E. D. El to *Victory XI.*, for Portland Dockyard.

Surg. Lt.-Comdrs: A. B. Grant to *Cambrian*, and J. Clarke to *President*, addl., for three months' post-gradua course.

ROYAL ARMY MEDICAL CORPS.

Maj. (Temp. Lt.-Col.) B. Biggar from the Secd. List restd. to the estabt. and relinquishes the temp. rank Lt.-Col.

Capts. D. H. Coats, G. T. Garraway, and P. G. Russ to be Majs.

A. MacMillan to be Lt. on prob.

ARMY DENTAL CORPS.

The undermentioned Lts. to be Capts.: F. F. Ansl and W. B. Purnell.

RESERVE OF OFFICERS.

Lt.-Col. R. McK. Skinner, having attained the age-lin of liability to recall, ceases to belong to the Res. of Offs.

SUPPLEMENTARY RESERVE OF OFFICERS.

B. R. Crossley to be Lt.

TERRITORIAL ARMY.

Maj. F. R. Harris, having attained the age-limit rel quishes his commission.

Maj. A. Morris, having attained the age-limit, retires, a retains his rank with permission to wear the prescrib uniform.

ROYAL AIR FORCE.

The undermentioned are granted permanent commissio in the ranks stated: Flight Lts. F. B. C. Lindes B. Crawford, and R. G. Freeman.

Flight Lt. T. Sheehan relinquishes his temporary co mission on completion of service and is permitted to ret his rank.

Medical News.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on May 16th, with Sir William Beveridge, the Vice-Chancellor, in the chair, Dr. Geoffrey Hadfield was appointed as from May 1st to the University Chair of Pathology tenable at the London School of Medicine for Women.

Dr. Hadfield received his medical education at St. Bartholomew's Hospital, where he was Harvey Prizeman in Physiology and Junior Scholar in Anatomy and Biology in 1908. He graduated in 1911, and proceeded to the M.D. degree (Pathology) two years later, being awarded the University Gold Medal. After resident appointments at St. Bartholomew's Hospital and at the Metropolitan Hospital, he was for a time medical registrar to the Dreadnought Hospital, Greenwich. He served in the Royal Army Medical Corps from 1914–19, since when he has been, respectively, recognised teacher, demonstrator, and assistant internal examiner in the Pathological Department of the University of Bristol. During this time he has been Pathologist, Bacteriologist, and Clinical Pathologist to the Bristol General Hospital, and since 1922 he has also been consulting Pathologist to the Bristol Mental Hospital, and other institutions.

Mr. Percival Hartley, D.Sc., was appointed as from August 1st, 1929, to the University Chair of Biochemistry tenable at the London School of Hygiene and Tropical Medicine.

Educated at the Technical College, Bradford, and the Yorkshire College, Leeds, Dr. Hartley obtained the B.Sc. degree of the Victoria University, Manchester, with first-class honours in chemistry in 1904. After research work at the University of Oxford, and at the Lister Institute, where he held a Grocers' Company research scholarship, he became D.Sc. Lond. in 1909. For the next four years he was physiological chemist to the Imperial Bacteriological Laboratory at Muktesar, United Provinces, India, and in 1913 he was appointed first assistant to the head of the Biochemical Department at the Lister Institute. From 1915–19 he was on war service with the R.A.M.C. in France and Belgium; from 1919–21 he was head of the Biochemical Department, the Wellcome Physiological Research Laboratories, and since 1922 he has been on the staff of the National Institute for Medical Research, Hampstead. In 1927 he held the William Julius Mickle Fellowship, and was appointed honorary secretary of the Medical Research Club.

The title of Professor of Experimental Pathology in the University was conferred on Dr. Archibald Leitch in respect of the post held by him at the Cancer Hospital.

From 1906–08 Dr. Leitch was assistant director of Middlesex Hospital Cancer Research Laboratory, and from 1908–12 director of the Caird Cancer Laboratory, Dundee. He was also Research Fellow at St. Andrews University from 1909–12. From 1912–20, except when on war service, he was pathologist to the Cancer Hospital, and since then he has been director of the Research Institute at that hospital.

The title of Reader in Pathological Chemistry in the University was conferred on Mr. C. R. Harington, Ph.D., in respect of the post held by him at University College Hospital Medical School.

From 1919–20 Dr. Harington was part-time demonstrator in Medical Chemistry in the University of Edinburgh, and from 1920–22 research assistant in the department of therapeutics. Since 1922 he has been lecturer in Pathological Chemistry at University College Hospital.

The Dunn Exhibitions in Anatomy and Physiology for 1928 were awarded to Mr. J. D. H. Bird, an internal student, of King's College.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At a meeting of the College, held on May 18th, Mr. Alexander Miles, the President, in the chair, the following 25 successful candidates, out of 84 entered, who passed the requisite examinations between Jan. 2nd and 7th, were admitted Fellows:—

Elsie V. Crowe, Alexander Cumming, F. W. Duthie, Philip Carson, Bernard Gluck, C. D. Gossage, Clermont Grantham-Hill, G. A. Hardwicke, Alfred Hobson, L. Wynn Houghton, C. W. Isaac, J. R. Learmonth, F. I. Lewis, E. O. Lloyd, Beatrice H. Lynn, C. R. McCash, B. L. McFarland, Samuel McMahon, E. C. Mekie, F. G. Phillips-Turner, F. E. Stayner, S. M. Vassallo, G. I. Wilson, C. L. Walker, and J. F. Zohrab.

The Higher Dental Diploma was conferred on Norman Gray and T. W. Watts.

The Bathgate Memorial Prize was awarded, after a competitive examination in Materia Medica, to J. I. Meikle.

THE decoration of Chevalier of the Legion of Honour has been conferred by the French Government on Mr. F. J. Morrin, surgeon to Jervis-street Hospital, Dublin. Mr. Morrin is medical adviser to the French Consultate in Dublin. Last year, while in France, he was involved in a railway accident at Abbeville, and rendered assistance to the injured. He was formerly head of the medical service of the National Army of the Irish Free State.

UNIVERSITY OF EDINBURGH.—Dr. F. A. E. Crew has been appointed to the new Buchanan Chair of Animal Genetics.

METROPOLITAN ASYLUMS BOARD.—Lord Doneraile was appointed chairman, and Mr. George Brittain vice-chairman, at a meeting of the Board on May 19th.

Sir StClair Thomson has been elected a corresponding member of the Société de Laryngologie des Hôpitaux de Paris, of the American Stomatological Association, and of the Philadelphia Laryngological Society.

THE SAMUEL AUGUSTINE COURTAULD INSTITUTE OF BIOCHEMISTRY at the Middlesex Hospital Medical School will be opened on June 14th, 1928, at 3.30 P.M. Sir Archibald Garrod will give an address.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., at 3 P.M. on Tuesday, June 19th. The Stephen Paget Memorial Lecture will be delivered by Sir Bernard Spilsbury, whose subject will be the Work and Responsibilities of a Pathologist.

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.—The fourteenth annual conference will be held in the Great Hall of the British Medical Association House in Tavistock-square on Monday and Tuesday, Oct. 15th and 16th. The subjects for discussion are the Occurrence of Tuberculosis among Primitive People, and the Principles Underlying a Scheme of Antituberculosis Measures in any Country.

WILLIAM MACKENZIE MEMORIAL MEDAL.—The first award of this medal, given in recognition of valuable contributions to ophthalmology, will be made to Dr. A. Maitland Ramsay, honorary director of the James Mackenzie Institute for Clinical Research, St. Andrews, and consulting ophthalmic surgeon to Glasgow Royal Infirmary. The presentation will take place in Glasgow, in the autumn, when Dr. Ramsay will deliver an address.

THE FOUNDLING SITE.—The court of governors of the Hospital for Sick Children in Great Ormond-street has approved the proposal for rebuilding it on the site of the Foundling Hospital should the site be obtainable. Mr. Stanley Hall, F.R.I.B.A., the architect consulted, reported that rebuilding was imperative and urgent, and that to reconstruct the hospital on the present site would be attended with "grave disadvantages as regards air, light, and health conditions generally."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The annual dinner was held in the Hall of the College last Saturday evening, Mr. Andrew Fullerton, President, in the chair. There was a large assembly of Fellows and guests. In proposing the health of the Governor-General, the President expressed the regret of the College at his absence from the dinner, and its hopes for his speedy restoration to health. He then gave the toast "Prosperity to Ireland," and spoke of the contribution toward that prosperity that could be made by the surgical profession. Replies were made by Lord Glenavy, Chairman of the Senate of the Irish Free State, and by Mr. R. J. Johnstone, a Member of the Parliament of Northern Ireland. Other speakers were Sir F. Conway Dwyer, Dr. R. W. Leslie, Sir John Moore, and Mr. James McMahon. At the end of the dinner Lord Glenavy, on behalf of the Council of the College, presented the President with a silver salver in recognition of his services to the College.—The annual elections in the College take place in the first week of June. Mr. T. E. Gordon, the present Vice-President, is the only candidate for the Presidency, and Mr. R. A. Stoney is a candidate for the Vice-Presidency.

REDUCTION OF NEONATAL MORTALITY.—The National Baby Week Council states that in 1926, in England and Wales, 48,757 children died in the first year of life, and that 45 per cent. of these deaths occurred in the first 28 days. The Council has recently received statistics from English towns in connexion with an offer of prizes by the *Daily News* for the greatest reduction in the neonatal death-rate during 1927, as compared with the previous five years' average. In the group of towns with a population of 100,000 and upwards, Leyton reduced its neonatal death-rate to 18·07 per 1000, a reduction of 35 per cent. on the previous five years; Bethnal Green to 19·97, a reduction of 26 per cent.; and Shoreditch to 23·31, a reduction of 20 per cent. Among the towns with a population of 50,000 to 100,000 Finchley reduced its neonatal death-rate to 12·7, Bath to 20·9, and Carlisle to 24·1, the reductions being 53, 36, and 33 per cent. respectively. The prize offered to the district which showed the greatest number of new-born lives saved goes to Lambeth, with Middlesbrough and Salford next in order.

MEMORIAL TO SIR WILLIAM LEISHMAN.—As we have already announced, a memorial tablet to the late Sir William Leishman, F.R.S., will be unveiled in the chapel of the Queen Alexandra Military Hospital, Millbank, S.W., at 11.30 A.M., on Saturday, June 2nd.

THE HIGHLANDS AND ISLANDS MEDICAL SERVICE. Major Walter Elliot, M.P., Under Secretary of State for Scotland, has opened the enlarged and modernised Stornoway Hospital and the extended Lewis Sanatorium. Major Elliot referred to the fact that in the Island of Lewis the number of cases of tuberculosis is proportionally three times as high as on the mainland.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—It was reported at the annual meeting of governors that the number of beds had grown from 87 in 1907 to 309 in 1927, the in-patients from 469 to 1716, and the out-patients' attendances from 9806 to 79,422. Over £108,000 has been collected towards the £125,000 required to complete the extensions in Great Portland-street and at the country branch at Stanmore.

UNIVERSITY OF LONDON ANIMAL WELFARE SOCIETY. Prof. F. T. G. Hobday, principal of the Royal Veterinary College, will take the chair at a public meeting to be held at King's College, Strand, at 5.30 P.M., on Thursday, May 31st, when addresses will be given on Man's Duty to Animals. Admission will be free without ticket. The society is precluded by its constitution from engaging in controversies relating to scientific experiments on animals.

BRITISH ASSOCIATION.—The preliminary programme of the annual meeting of the British Association for the Advancement of Science, which will be held this year at Glasgow, has now been issued. On Sept. 5th Sir William Bragg, F.R.S., who will be President of the Association in succession to Sir Arthur Keith, F.R.S., will deliver an address on Modern Developments of the Physical Sciences and Their Relation to National Problems. Sectional meetings will be held daily from Sept 6th to 12th, except on Saturday and Sunday. The Presidents of the Physiological and Psychological Sections are Prof. C. Lovatt Evans, F.R.S., and Prof. T. H. Pear. A detailed programme may be had from the secretary of the British Association, Burlington House, London, W. 1.

BRACEBOROUGH SPA.—This spa, which has a history of 100 years, was reopened on Saturday last, May 19th, by the Earl of Ancaster in the presence of a large company, medical and lay, who were entertained later at luncheon by the Mayor and Corporation of Stamford and the directors of the company responsible for carrying on the work of the development of the spa. The waters of Braceborough Spa were first recommended to George III. by Dr. Francis Willis, who resided at Braceborough. The king, who suffered at this time from a skin affection, bathed at Braceborough, it is said, with favourable results; the site of the bath in which he bathed has been preserved, and on it there have been erected now a small pump room and baths. It has been estimated that the amount of water available from the springs daily is 200,000 gallons, and, according to Dr. Alfred Eddowes, consulting physician, St. John's Hospital for Diseases of the Skin, it has now been found successful in the treatment of many of the conditions amenable to balneology, especially psoriasis. At the civic luncheon Dr. Harold Pritchard, senior physician to the West London Hospital, spoke warmly of the development of spa treatment and its value to the public.

THE LATE MR. W. J. FOSTER.—The death occurred at Boscombe on May 11th of Mr. William James Foster, consulting surgeon to the Royal Berkshire Hospital. He qualified in 1890 and became F.R.C.S. Eng. two years later, after holding a number of house appointments at St. Mary's Hospital, where he had received his medical training. In 1893 he went to Reading as successor to the late Dr. Richardson, and in 1899 he was appointed assistant surgeon to the Royal Berkshire Hospital, becoming full surgeon in 1914. During the war he was in charge of one of the main surgical blocks of the Reading War Hospital, with a captain's commission in the R.A.M.C. (T.). A pioneer in radiographic work in Reading, he had much to do with developing the X ray department at the Royal Berkshire Hospital, and his opinion as a radiologist was especially valued by his colleagues, as it was backed by expert surgical opinion. Mr. Foster kept himself well abreast of advancements in surgery and, besides his professional work, took a keen interest in the management of the hospital, of which he was senior surgeon at the time of his retirement in 1924. On leaving Reading he settled in the Bournemouth district and ultimately built a house at Boscombe. He leaves a widow and one daughter.

TRAINING AND EMPLOYMENT OF MIDWIVES.—The Minister of Health has appointed a Departmental Committee, whose terms of reference are: "To consider the working of the Midwives Acts, 1902 to 1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery), and the conditions under which midwives are employed." The Committee is appointed with the concurrence of the Central Midwives Board, and its appointment forms part of the measures for dealing with the problem of maternal mortality and morbidity. The members are: Sir Robert Bolam, F.R.C.P. (chairman), Dr. J. W. Bone, Dame Janet Campbell, M.D., Lady Cynthia Colville, Dr. W. A. Daley, Dr. J. S. Fairbairn, Dr. T. Eustace Hill, Miss Alice Gregory, Mr. A. B. Maclachlan, Dr. F. N. Kay Menzies, Mrs. Bruce Richmond, and Miss Stephenson. The secretary will be Mr. W. H. Howes, of the Ministry of Health, to whom communications may be addressed.

GIFT TO A CHILDREN'S HOSPITAL.—Sir Gomer Berry, chairman of the committee of management of the Infants Hospital, Vincent-square, London, has given £50,000 to the hospital as a memorial to his wife. It will be used for the erection of a new maternity block.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY, May 31st.—10 A.M. to 12.30 P.M., LARYNGOLOGY AND OTOLOGY. Summer Meeting. *Papers:* Mr. Rake Achalasia and Degeneration of Auerbach's Plexus Mr. A. J. Wright: Silent Tracheotomy, Its Significance tion. Dr. Lowndes Yates: Methods of Estimating the Liability to Post-operative Hæmorrhage from Unsutured Wounds. Mr. W. M. Mollison: Dysphagia Due to Pharyngeal Paralysis. 2.30 P.M. to 4.30 P.M. *Papers:* Dr. Jobson Horne: Cancer of the Vocal Cords. Dr. Watson-Williams: Familial Infectivity of Chronic Sinusitis. Sir StClair Thomson: Intrinsic Cancer of the Larynx Operated Through a Laryngo fissure. (Lantern demonstration of immediate and lasting results in 70 cases.)

FRIDAY, June 1st.—10.30 A.M. to 12.30 P.M., LARYNGOLOGY AND OTOLOGY. *Papers:* Prof. Dr. Otto Mayer, of Vienna (Dalby Prize Winner): The Pathology of Otosclerosis. Dr. A. Lowndes Yates: A Working Hypothesis for Research in Otosclerosis. Mr. Harold Kisch: The Use of Temporal Muscle Grafts in the Radical Mastoid Operation. Mr. Douglas Guthrie: Fat Grafting in Mastoid Surgery. 4 P.M. to 6.30 P.M. *Cases and Specimens* will be shown by Mr. E. D. D. Davis, Mr. Alexander Tweedie, Mr. Douglas Guthrie, Dr. T. B. Jobson, Sir James Dundas-Grant, Mr. Harold Kisch, Mr. M. Vlasto, Mr. Herbert Tilley, Mr. V. E. Negus, Mr. Norman Patterson, Mr. J. A. Gibb, and Mr. Broughton Barnes. The Library will be open until 10 P.M. *Dinner:* Members will dine together, at the Hotel Victoria, at 7.45 P.M. The Dinner (to which ladies are invited) will be followed by a dance.

SATURDAY.—10.30 A.M. (Cases at 9.30 A.M.) LARYNGOLOGY AND OTOLOGY. *Papers:* Prof. G. Portmann (Bordeaux): Vasomotor Affections of the Internal Ear. Mr. W. S. Sharpe: The Influenza Ear. *Cases and Specimens* will be shown by Dr. T. A. Clarke (introduced by Mr. Cleminson), Dr. T. B. Jobson, Sir James Dundas-Grant, Mr. Harold Kisch, Mr. W. Ibbotson, Mr. T. B. Layton, Dr. O. Popper, Dr. Dan MacKenzie, and Mr. Norman Barnett. There will be a display of instruments and apparatus in Rooms 3 and 4 during the period of the summer meeting.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, June 1st.—8.30 P.M., General Meeting. Papers will be read by Dr. L. S. T. Burrell and Dr. S. F. Gloyne on Syphilis in Relation to the Ætiology and Diagnosis of Tuberculosis. A discussion will follow.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

WEDNESDAY, May 30th.—5.15 P.M. (at the London School of Hygiene and Tropical Medicine, Endsleigh-gardens, Euston-road), Dr. Joaquin J. Vallerino (Panama): Lantern slide demonstration on the Value of X Rays in Intestinal Amœbiasis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 28th, to SATURDAY, June 2nd.—ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C. Clinical urological demonstration by Mr. Ogier Ward at 2 P.M. on Wed.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Clinical demonstration by Dr. H. C. Semon from 4.30 to 5.30 P.M. on Thurs. The above are free.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Post-graduate course in Dermatology every afternoon.—NATIONAL HOSPITAL, Queen-square, W.C. Cour

in Neurology for two months. Particulars and tickets from the Fellowship of Medicine. Further particulars from the Secretary.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.

TUESDAY, May 29th.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Department.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY, June 1st.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Children's Medical Out-patients.

Daily, 10 A.M. to 5 P.M., SATURDAYS, 10 A.M. to 1 P.M., In-patients, Out-patients, and Special Departments. Anæsthetic and Operative Surgery Courses.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

WEDNESDAY, May 30th.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

THURSDAY, May 31st.—4 P.M., Mr. J. Swift Joly: Practical Points in Urinary Disease.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.

THURSDAY, May 31st.—5 P.M., Dr. G. V. Anrep: Pathology of Conditional Reflexes.

NATIONAL HOSPITAL, Queen-square, W.C

TUESDAY, May 29th.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Subacute Combined Degeneration.

THURSDAY.—3 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30, Dr. Walshe: Neurosyphilis (2).

FRIDAY, June 1st.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educative Exercises (in Exercise Room).

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

THURSDAY, May 31st.—5 P.M., Dr. W. J. O'Donovan: Skin Diseases of Animals Transmissible to Man.

FRIDAY, June 1st.—5 P.M., Dr. W. Griffith: Bullous Eruptions.

MIDDLESEX HOSPITAL MEDICAL SCHOOL, Cleveland-street, W.

TUESDAY, May 29th, WEDNESDAY, May 30th, and THURSDAY, May 31st.—5.30 P.M, Dr. John Eason: Graves's Disease.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, June 1st.—3.30 P.M. (at the Royal Hospital), Dr. Mackie: Strabismus.

Appointments.

GERRARD, E. A., M.B., Ch.B. Manch., has been appointed Resident Obstetric Surgeon to St. Mary's Hospitals, Manchester.

GRAHAME, E. W., M.B., Ch.B. Glasg., Second Assistant Medical Officer to the Croydon Board of Guardians.

IVY, S. I., F.R.C.S. Eng., L.R.C.P. Lond., Assistant Surgeon to the London Jewish Hospital, Stepney Green, E.

KINNER, T. E., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for Wivenhoe.

KILLOUGHBY, W. M., M.D., B.Chir. Camb., D.P.H., Medical Officer of Health, City of London.

Bolingbroke Hospital, Wandsworth: LLOYD, W. E., M.D. Lond., M.R.C.P. Lond., Honorary Physician; and LUMSDEN, A., M.B., Ch.B. Aberd., Out-patients' Officer, Ophthalmic Department.

Leeds Public Dispensary: MCADAM, W., M.D., Ch.B. Glasg., F.R.C.S. Lond., Hon. Physician: and MOIR, P. J., M.B., Ch.B. Glasg., F.R.C.S. Eng., Hon. Surgeon.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. At rate of £200. Also H.S. At rate of £150.

Belfast, Ulster Hospital for Children and Women.—Hon. P. Also Hon. Asst. P.

Bethnal Green Hospital, London, E.—Asst. M.O. £400.

Birmingham and Midland Eye Hospital, Church-street.—H.S. £110.

Birmingham City Education Committee.—Asst. Sch. M.O. £600.

Burnley, Primrose Bank Institution.—Res. M.O. £300.

Cambridge, Papworth Village Settlement.—Second Asst. M.O. £250.

Cambridge University Pathological Laboratory.—John Lucas Walker Studentship. £300.

Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.

Carlisle, Cumberland Infirmary.—Jun. H.S. At rate of £135.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Out-patient Statistical Reg.

City of London Hospital for Diseases of Heart and Lungs.—Two H.P.'s. At rate of £100.

Derby, Walton Sanatorium, near Chesterfield.—Locum Res. Asst. M.O. At rate of £350.

Dorchester, Dorset Mental Hospital, Herrison.—Jun. Asst. M.O. £300.

Down County Regional Education Committee.—Sch. M.O. £750.

Eastbourne, Princess Alice Memorial Hospital.—Jun. H.S. At rate of £100.

East London Hospital for Children and Dispensary for Women.—H.P. At rate of £125.

Essex, Administrative County of.—Three Asst. County M.O.H.'s. Each £600.

General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.

Hastings, Royal East Sussex Hospital.—Hon. Asst. Surg.

Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. £250. Also H.P. and H.S. Each £50.

Ipswich, East Suffolk and Ipswich Hospital.—Hon. Asst. Ophth. S.

Leamington Spa, Warneford General Hospital.—Res. H.P. £165.

L.C.C. Mental Hospitals' Service.—Eighth Asst. M.O. £300.

Manchester, Ancoats Hospital.—H.S., Orthopædic. £100.

Manchester City.—M.O. £600.

Manchester Northern Hospital for Women and Children.—Sen. H.S. and Jun. H.S. £130 and £100 respectively.

Manchester Royal Infirmary.—Dickinson Research Travelling Scholarship in Medicine. £300.

Manchester Royal Eye Hospital.—Sen. H.S. £150. Jun. H.S. £120.

Manchester, Salford Royal Hospital.—Hon. Asst. P. Also Cas. H.S. At rate of £125.

Newport, Mon., Royal Gwent Hospital.—Hon. S., two Hon. Asst. S.'s. Also Hon. Asst. Ophth. S.

Nottingham City Mental Hospital.—Deputy Med. Supt. £650.

Plumstead and District Hospital, High-street, S.E.—First Asst. M.O. £400.

Poplar Hospital for Accidents, East India Dock-road, Poplar, E.—Second Res. O. £175.

Pudsey, Borough of.—M.O.H., &c. £273.

Queen Mary's Hospital for the East End, E.—H.P.'s, H.S.'s, &c.

Queen's Hospital for Children, Hackney-road, E.—Cas. O. Also H.S. Each at rate of £100.

Royal College of Physicians of London.—Charles Murchison Scholarship in Clin. Med. 20 guineas.

Royal College of Physicians of London and Royal College of Surgeons, England.—Streatfeild Research Scholarship in Med. and Surg. £250.

Royal Free Hospital, Gray's Inn-road, W.C.—H.S.'s, H.P.'s, &c.

Royal Naval Medical Service.—Surg. Lieutenants. £453.

Royal Northern Hospital, Holloway, N.—Clinical Asst.

St. Mary Abbots Hospital, Marloes-road, W. 8.—Asst. M.O. £250.

St. Mary's Hospital, W.—Surg. Reg. £200.

St. Thomas's Hospital Medical School.—University Chair of Dietetics. £1000.

Stafford, Staffordshire General Infirmary.—H.P. At rate of £150.

Surrey County Sanatorium, Milford.—Med. Supt. £900.

Swansea Hospital.—H.S. £150.

Tunbridge Wells, Tonbridge Union Institution, Pembury.—Asst. M.O., &c. £275.

University of London, South Kensington, S.W.—Sir William Dunn Chair of Pathology. £1330.

Warrington Infirmary and Dispensary.—Jun. H.S. £175.

Weir Hospital, Grove-road, Balham, S.W.—Jun. Res. M.O. £150.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Res. Asst. Cas. O. Also Aural and Ophth. H.S. Each at rate of £100.

Wrexham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £100.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Salford and Stretford (Lancashire).

Births, Marriages, and Deaths.

BIRTHS.

DULAKE.—On May 18th, at South-walk, Reigate, Surrey, the wife of Lawrence Dulake, M.B., B.S., of a son.

MILLER.—On May 16th, at 514, Fulham Palace-road, S.W. 6, the wife of T. Duff Miller, M.D., F.R.F.P.S., of a son.

DEATHS.

CLARKE.—On May 22nd, 1928, at 3, Chandos-street, Cavendish-square, W., Kate Litton, the dearly loved wife of Ernest Clarke, C.V.O., M.D., F.R.C.S.

HARRIS.—On May 18th, at Beresford-road, Birkenhead, Alfred Charles Edward Harris, M.B., F.R.C.S. Edin., J.P., aged 77 years.

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

OPENING OF THE PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN.

THIS new hospital, of which the out-patient department has been in use since last December, was formally opened by the King and Queen on May 21st. Originally founded as a dispensary in 1840, the hospital became the Kensington Dispensary and Children's Hospital in 1896, when a ward of 11 beds was added to the inconvenient building in Church-street, Kensington, where out-patient clinics were held. Largely owing to the energy of Princess Louise, Duchess of Argyll, the old site was sold in 1925 and a new site purchased at the corner of St. Quintin's-avenue, North Kensington.

Good response was received to the appeal for the £80,000 needed to build a modern hospital for children. At the end of 1926 the foundation stone was laid and in 1927 an honorary medical staff of high standing was appointed. Accommodation for between 30 and 40 beds is available in the two ward blocks already erected and it is hoped, when funds permit, to build a nurses' home, so as to release the upper floors for the reception of 40 more cots. Provision for out-patients includes ophthalmic, ear, nose and throat, orthopædics, X ray, electrical treatment, and massage departments. A special arrangement enables beds to be reserved for L.C.C. school-children undergoing the operation for tonsils and adenoids, in order that they may be retained in the hospital for two nights. The hospital is also responsible for providing a school treatment centre for L.C.C. school-children, and for this some financial assistance is received. There is also a special centre for the care and investigation of rheumatism in children. Women out-patients receive medical treatment, but there is no in-patient accommodation for them.

The population of Kensington is approximately 94,000 and a children's hospital has long been needed. The King, when opening the hospital, referred to the close association between the Royal Family and the Kensington Dispensary and praised the prudent and far-sighted policy shown in the selection of the site.

The honorary medical staff of the hospital, some of whom were presented to the King, are as follows:—Consulting physician: Sir William Willcox. Consulting surgeon: Sir Herbert Waterhouse. Physicians: Dr. P. Montague Smith and Dr. Sydney A. Owen. Surgeons: Mr. Neil Sinclair, Mr. R. M. Handfield-Jones, and Mr. Eric Lloyd. Assistant physicians: Dr. Douglas Rice-Oxley, Dr. Janet Aitken, and Dr. R. C. Lightwood. Assistant surgeon: Mr. Robert Paton. Ear, nose, and throat surgeon: Mr. G. Douglas Robertson. Ophthalmic surgeon: Mr. A. E. Loosely. Dermatologist: Dr. Lewes N. Gibbes. Anæsthetists: Dr. Ernest F. Travers, Dr. Aileen Chester, and Mrs. Audrey Marsden. Medical officer in charge of Electrical Department: Dr. J. F. Carter Braine. Radiologist: Dr. H. M. Worth. Dental surgeon: Mr. L. Russell Marsh. Pathologist: Dr. Robert Donaldson.

"TO MOTHERS AND FATHERS."

THE sub-title of this booklet,[1] compiled by the Association of Infant Welfare and Maternity Centres, is "How to Keep Yourselves and Your Children Well and Strong." It is now in a ninth edition, and the publishers state that the sales have approached half a million. This success may be attributed to the soundness of the teaching, the simplicity with which this teaching is presented, and the low price. Though the book is intended as a health guide for parents, they are warned that it cannot replace expert medical advice, and in the very first paragraph the expectant mother is recommended to put herself in the hands of a skilled doctor or midwife, who alone is in a position to judge of the normality or otherwise of her condition. A hopeful attitude is the prevailing tone, and emphasis is laid on the desirability of preventing troubles rather than putting them right when they have developed. The matters treated with gravity are those which should be so treated—miscarriage, complications of pregnancy, artificial feeding, infantile diarrhœa, colds and their sequelæ in children, and the like.

There is a useful explanatory chapter on adenoids, and another on the common infectious diseases. The chapters on management and character training are full of practical wisdom.

THE ORGANISATION OF HOSPITALS.

To the Editor of THE LANCET.

SIR,—I would be glad to receive some information as regards the general organisation of hospitals in England. The reorganisation of the British hospital at Buenos Aires is under consideration. A point has been raised as to whether the staff of the hospital should or should not be represented on the committee of management. The view of the staff is that each year they should elect a member to represent them on the Committee, so as to establish a point of contact between the two bodies. The view of the Committee is that such is not the custom in British hospitals, and, even if it were, it has no advantage.

I should be much obliged if you could give me some information as to what is the custom in England.

I am, Sir, yours faithfully,

ROBERT E. HALAHAN.

Buenos Aires, April 19th, 1928.

*** There is no rule on this subject. In many English hospitals the medical staff are represented on the management; probably in quite as many they are not. There are advantages in the staff being represented.—ED. L.

NURSERY SCHOOLS.

ON the whole the President of the Board of Education rebutted with considerable success the attacks made last week in the House of Commons on its recent policy, but the lack of nursery schools hardly seems to be receiving sufficient attention from him. Mr. Trevelyan, who in Committee of Supply moved the reduction in the vote for the salaries and expenses of the Board of Education, criticised the large classes in our elementary schools and the unsatisfactory state of many school buildings, but it was to his plea for greater care of the child between the ages of 3 and 6 that medical opinion is likely to give strongest support. The chief medical officer of the Board of Education is known to have the extension of the number of nursery schools greatly at heart, and apt quotations of words from his pen in praise of their activities formed a convenient weapon for the critics of Government policy. The arguments used by Mr Trevelyan, Mr. P. Harris, and Lady Astor were not easy to answer and indeed no attempt was made to answer them. Instead the President emphasised his view that the chief problems of his department were the provision of better education for older children in the elementary schools and better opportunities for their further education when they left school. No one can deny the urgency of these needs, but they seem to be occupying him to the exclusion of those of the child at the other end of the scale. There are only 26 nursery schools in this country, accommodating 1361 children. Of these schools 11 were provided by private enterprise. The average proportion of diseased and delicate children entering elementary schools at the age of 5 is, according to Lady Astor, from 30 to 40 per cent., whereas among those who attend nursery schools the proportion is only 7 per cent. Statisticians might protest that the population at risk is so very much smaller in the latter group that the figures are hardly comparable; but the remarkable difference in health and nutrition of children who have been under constant supervision from infancy to school age is not in dispute. The gap in medical supervision between the infant welfare centres and the elementary schools is responsible for the development of certain diseases which are very much more expensive to cure than to prevent. Since 1918, when special provision was made for the establishment of nursery schools, local authorities have been slow to take advantage of their powers to establish them. More active encouragement from the Board of Education will be necessary.

"RHODIAN" CIGARETTES.

WE have received from Messrs. Lambert and Butler a sample of cigarettes made exclusively from Rhodesian grown tobacco which they claim to be the first "all-British" cigarette. The methods of producing Rhodesian tobacco have greatly improved in the last few years and the "Rhodian" cigarettes have a flavour which many will appreciate. They are slightly larger in size than the average cigarette and are put up in popular boxes of 10 and 20.

The Past in Picture.—To-day (Friday), at 3 P.M., an exhibition of Naval, Military, and Historical Pictures will be opened at the Parker Galleries, 28, Berkeley-square, Mayfair, London, by Earl Beatty, and will remain open daily from 10 A.M. till 6 P.M., except on Saturdays, when it will close at 1 P.M. A well-illustrated booklet forms an introduction to the collection.

A Lecture
ON THE
OVARIAN HORMONE.

Delivered at the Institute of Pathology and Research, St. Mary's Hospital, on May 10th, 1928,

BY E. C. DODDS, M.D., PH.D. LOND.,
PROFESSOR OF BIOCHEMISTRY, UNIVERSITY OF LONDON; CHEMICAL PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

COMMERCIAL medical literature, and more particularly that emanating from America, would seem to indicate that it is more or less waste of time to go over such well-established and worked-out ground as that of the ovarian hormone. I could read you innumerable extracts from commercial publications proving conclusively that the whole question of ovarian substitution therapy has been completely worked out, and that the physician has only to buy the tablets and supply them to his patients. This type of literature with its horrible jargon and incredible claims has put the subject in a distasteful position. It is desirable, therefore, to see where we really do stand. I propose to make a very brief historical summary and then to attempt to show the various experimental researches leading up to the isolation of the ovarian hormone, concluding with a few remarks on the clinical aspect.

HISTORICAL SUMMARY.

The fact that the ovaries are associated with sexual characteristics has been known for a long time, and this knowledge has been in the possession of farmers and breeders from time immemorial. Although the effects of complete ovariectomy have been studied for generations, it would appear that only comparatively recently has the possibility of substitution therapy in human beings been thought of. When one explores the literature in the hope of finding the first workers to suggest substitution therapy, there arises the difficulty common to all such researches; when what is apparently the earliest observation on this problem is selected and put forward as the first experiment, it is usual to find that another worker can produce a set of experiments dating from an earlier period. I will, therefore, quote some of the earlier work without prejudice, however, as to whether it is really the earliest observation.

In the year 1900 Knauer[1] performed an elaborate series of experiments in which animals were spayed, and after they had remained in a quiescent state for a considerable period, their sexual activities were reawakened by ovarian grafts. From this he concluded that the ovaries possessed an internal secretion responsible for the phenomena of œstrus, and that they had a function quite apart from their main and obvious one—namely, the production of ova. During the same year, Theodore Landau[2] studied the effects of administering ovarian tissues to patients suffering from climacteric symptoms, and in addition he gave his preparations to young women who had undergone the operation of double oöphorectomy. According to this worker, the result of his experiment was entirely satisfactory, the symptoms were abated, menstruation was established, and the patients improved rapidly upon treatment.

These publications caused a considerable amount of interest in this subject and many papers appeared from the year 1900 onwards. A typical example can be quoted in the work of Mainzer, 1903.[3] In order to test whether the effects of the treatment were due to suggestion, Mainzer performed a series of control experiments. Without the knowledge of the patient he substituted dry meat for the ovarian tissue, and found that the patient immediately relapsed into her former state; from this he concluded that the amelioration of symptoms could be attributed solely to the administration of the ovarian tissue. The method of preparing this material was extremely crude. The ovaries were merely dried at a low temperature and the resultant material made up into tablets. It would be possible to continue almost indefinitely to quote observations of this type, results which, according to the publications, were entirely satisfactory. One great point in all these investigations to be noticed is that the workers give the tissue by the mouth. As we shall see later it is difficult to understand the good results, because the workers of late years have shown that the extract by mouth is inactive. There is one exception to the oral administration: Federoff[4] injected crude extracts subcutaneously and intravenously. But, since he only reports the effects of his extracts upon the blood pressure and pulse-rate, one can conclude that his material was very toxic.

EXPERIMENTAL RESEARCHES.

Yet another point will at once strike the critical observer. In all these experiments no animal standardisations were performed at all. The investigators proceeded straight to the clinical trial. Starting in 1900, we can trace the observations right up to 1912 before there is any reference to animal tests. We can, in fact, state that all the exact work on the ovarian hormone commenced in this year. The most important observation was performed by Adler.[5] He showed that by repeated injections of crude watery extracts of the whole ovary it was possible to produce the typical signs of œstrus in animals. This careful series of observations was checked by histological investigations of the uterus and vagina, and there can be no doubt that he succeeded in obtaining potent preparations. We can, therefore, begin our serious consideration of the literature on the subject from this point. From 1912 onwards we have before us a series of careful experiments, particularly on the chemical side. The standardisation of the preparation was carried out on animals, and therefore the whole question was put on a much sounder footing. In the experiments about to be quoted, two more or less new aspects will strike the critical observer. In the first place, it will be found that practically all the workers from 1912 onwards began to associate the active principle with the fat-soluble material; that is to say, practically all methods of preparation had, as an essential step, the extraction of the tissues with some volatile organic solvent. In the second place, it will be noted that the workers tacitly assumed that any preparation which would produce sexual activities in animals would also produce menstruation in the human subject. For instance, it is quite obvious from a study of the work of 1912 onwards that the authors were certain that any extract producing œstrus or rutting symptoms in animals would, without doubt, be a potent therapeutic agent in the treatment of ovarian deficiency in the human being. As we proceed we shall have to examine both of these points, and it will be found that the first theory, with regard to the fatty nature of the active principle, is partially correct; whilst the second assumption is one upon which I doubt very much whether it is possible to give a definite opinion at the present time.

Since the method of testing extracts is the most important and, in fact, the only criterion by which it is possible to assess the value of the earlier work, it will perhaps be as well to consider an investigation based on careful animal work. There can, of course, be no doubt that the results of the very early workers who proceeded straight to clinical tests were fallacious and completely lacking in quantitative basis.

Many of the earlier publications dealing with the chemical and physiological properties of the hormone left no clear-cut account of the standardisation. Discounting various observations which we now know to be incorrect, undoubtedly one of the clearest pieces of work was that of Herrmann and Fraenkel,[6] and the following account is taken from the patent specification:—

Finely minced ovaries are extracted several times with some volatile substance—preferably alcohol. By extracting

the previously dried tissues the best results are obtained. The solid matter has to be filtered and pressed in order to separate it from the solution, and the alcohol has to be distilled off. Thus a watery residue is left with the active material present as a suspension. This residue is then shaken up with ether in a separating funnel, and in this way the suspended material is removed from the water. The ether solution is then evaporated down, and acetone is added to precipitate the lipoidal fraction which may be separated either by filtration or by centrifugation.

The active principle is obtained when the clear solution has been evaporated to dryness. The following method purifies it. After precipitation of the lipoids with acetone, the solvent is evaporated off and the residue is dissolved up in alcohol. The addition of an alcoholic solution of lead acetate precipitates fatty acids. The solution is evaporated to dryness after the removal of the excess lead, and is then distilled in the highest possible vacuum. The hormone distils over between 190° and 210° C. The distillate contains in addition some cholesterol esters, and is treated with a small volume of cold alcohol. The hormone readily dissolves and much of the cholesterol compound crystallises out and can be separated by filtration. The alcohol is evaporated off and the oily residue is subjected to a second distillation in high vacuum. Placenta may be used for the preparation of this substance.

Properties.—"A light, viscid oil at normal temperature" is the substance. It may be distilled in a high vacuum at a temperature of about 200° C. These preparations give the reaction for cholesterol, but active material can be obtained almost free from cholesterol. It was found to contain only carbon, hydrogen, and oxygen when analysed, and to give the following percentage composition: C. 81·33 to 81·62; H. 11·32 to 11·49.

Herrmann and Fraenkel indicate what they consider to be a criterion of activity by stating that if the substance is administered subcutaneously to prepuberal rabbits for a prolonged period, the onset of premature puberty is noted. They also state that an extract, to be considered active, must produce rutting symptoms out of rutting time, and if administered over a prolonged period should cause a very great increase in the size of the uterus and appendages. The work of Herrmann and Fraenkel set up certain definite standards for determining the activity of the preparation, and the majority of serious workers adhered to this type of method.

Biological Test of Activity.

It can be seen, however, that it is very difficult to define the activity in a quantitative manner by this type of method; it is only possible to say whether a preparation is active or not. Fortunately the application of some purely biological work has resulted in the gradual replacement of this method by one which now promises to develop into a fairly correct quantitative method. In 1917 Stockard and Papanicolaou[7] noted that the type of cells obtained from a vaginal smear of small mammals was influenced by the appearance of œstrus, and this work was extended to embrace other animals by various workers. The vagina is represented by a solid cord of cells in the pre-puberal rat, appearing in the vulva merely as a slightly raised mark. The opening out of this strand of cells shows the onset of puberty. In the non-œstral rat, smears of the vagina, stained with hæmatoxylin and eosin, show the presence of epithelial cells in various stages of nuclear degeneration and cytoplasmic shrinkage, together with some polymorphonuclear cells. Congestion of the vulva may accompany the onset of œstrus, and the vaginal opening appears larger. The smear shows nucleated epithelial cells alone. The vagina is nearly dry when œstrus is at its height. The smear shows cornified, non-nucleated, red eosin-staining cells. The presence of these cells makes the diagnosis certain, though external signs may be absent. These changes take place in reverse order as the œstrus recedes. These researches provided an accurate means of determining the onset of the sexual cycle in animals, and so could be made the basis for a method of standardising the ovarian preparations.

To Allen and Doisy[8] belongs the credit of first suggesting that the ovarian extracts should be tested by this type of method. They repeated the work of Herrmann and Fraenkel on the chemical side, and applied the Stockard and Papanicolaou smear metho to the study of the activity of the preparations. B this means a very great advance was made.

Thus the potency of ovarian preparations may b measured by two methods. A unit could be base upon the quantity required to produce the typic signs of puberty in a rat long before the age at whic the condition supervenes naturally, or the amoun required to induce œstrus in a castrated anim might form the basis of a method of standardisatio The former method would have certain disadva tages; for instance, the exact date of the birth the animal would have to be known, otherwise would be difficult, even with control animals of th same litter, to avoid the possibility of natural puberty Also, a fresh rat would have to be used for eac experiment, otherwise any positive result occurrin might be said to be due to additive effect. On th other hand, if the second method were employe one animal could be used for any number of tes when the reaction had subsided. The operation double ovariectomy in young rats is quite easy. A incision is made through the back, parallel to th quadratus lumborum, the ovary is seized through th wound and cut off. It is advisable to ligature th pedicle in large rats before closing the incisio Michel's clips are used to close the skin wound. T make certain that the ovaries have been remove sections of the tissues should always be cut. Sexu maturity cannot be achieved by natural means this operation is performed before puberty. "puberal" dose would seem to have to be great than an "œstral" dose. The "œstral" unit h advantages over the "puberal" unit, which ha led to its adoption.

Difficulties of Standardisation.

It can readily be seen that this method has all th possibilities of being capable of developing into really quantitative reaction. A number of anima are ovariectomised and are swabbed daily for o week. During this period the animal should rema in a state of dicœstrus. Any that show cornificatio during this period must, of course, be rejected. Wh a batch of animals is obtained that gives a uniform negative swab over a prolonged period, standardis tions can be performed upon them. It would appe at first sight that one could inject a series of anima with descending doses and thereby obtain a minimu quantity of extract that would give a full œstr response and thus could be defined as a unit. Th method has been used up to August of last year, a it was assumed that the results were perfectly u form. The yields were calculated on the basis of th type of standardisation, and a great deal of elabora work has been done with regard to the distributi of the active principle throughout the body. Unfo tunately, it has been shown that the above procedu is fraught with many difficulties and is, in fact, qui unreliable from a purely quantitative point of vie In the middle of last year Coward and Burn[9] pu lished a paper in which they examined this type method, and the results arrived at by them are important that it is necessary to consider them some detail. As they point out, it is obvious th the method of standardisation depends upon t assumption that the smallest dose of the extra required to produce œstrus in one rat will not serious differ from that required in another. This has be tacitly assumed by all workers, but the investigatio of Coward and Burn prove conclusively that this not the case.

From a prolonged series of investigations they show th the amount of extract required to produce œstrus in a sin rat may vary by as much as 1000 per cent., and from t they conclude that all methods of standardisation bas upon a gradual reduction of the dose in a small series animals must be entirely fallacious. In order to determi the relation between the weight of extract injected and t number of animals giving a full response, Coward and Bu took a preparation of the extract of which 5 mg. wou seem to be a dose that would send the majority of a sm number of animals into œstrus. Ninety rats were tak

ıd were injected with 5 mg. each. The rats were swabbed
the manner already described, and the slides were examined
find out how many were going into œstrus. After the
ıimals had passed their cycle, the experiment was repeated,
ıt in each experiment a different dose of the hormone was
ven. The general conclusions that can be formed from a
udy of this work show that, as the dose of the extract is
creased, the number of rats responding does not increase
roportionally; in fact, the number is smaller than would
ave been expected. One point that is demonstrated very
early is that the minimum effective dose is by no means
ıe same for all rats, and therefore some new criterion has
be obtained in the standardisation of the extract. From
statistical consideration these workers decided to define
rat unit of the extract as that quantity of material which
ould produce the full œstral cycle in 50 per cent. of the
ries of injected animals. They also demonstrated very
early that no conclusive results could be obtained unless
least 20 animals were used.

We have repeated the whole of this work and have
lly confirmed it. The method we now employ is
ıat described—viz., an injection of at least 20
ıimals with a dose that will just give a response in
per cent. of the animals. Coward and Burn
ıowed that the mouse unit is the same as the rat
ıit when tested by this method, thereby pointing
ıt that the amount of extract necessary to produce
e complete cycle bears little or no relation to the
ody-weight of the animal. These authors also stated
ıat the extract was just as active in one dose as it
as when the amount was split up into a series of
jections given over a period of days. As will be
en later, we have found that these statements do
ot apply to the water-soluble form of the hormone.

Oily and Watery Preparations.

The chemical work on the process of preparation
rformed by Allen and Doisy consisted mainly in
e extension of the work of Herrmann and Fraenkel,
th the result that a more potent preparation was
tained. They maintained that an active principle
as located in the liquor folliculi of the ovaries, and
ey elaborated a method for the preparation from
is source. By their later methods they claim to
ve produced a substance of which the rat unit
about one-hundredth of a milligramme, but it must
borne in mind that they have not apparently used
e statistical method elaborated by Coward and
ırn. With regard to the distribution of the hormone,
ntrary to the views of Allen and Doisy and their
-workers, we have found that the residual ovarian
sue, after removal of the liquor folliculi, still con-
ns a considerable quantity of the hormone, and we
me to the conclusion that the active principle
s distributed throughout the ovaries. This has
o been demonstrated by Parkes and Bellerby.[10]
r the preparation on a large scale the majority of
rkers use the placenta, and as the human organ is
far the most easily obtained in London, this has
en used more or less exclusively.

Up to the present we have only referred to the
paration of the hormone in the oily form. This
e of preparation has to be put up for injection
her dissolved in oil or emulsified in sodium bicar-
nate solution, but this has been found far from
table for a hypodermic injection. The material
ulting from the ordinary process of alcohol extrac-
n has a unit as defined by Coward and Burn of
ne 8 to 10 mg. It follows, therefore, that if a large
se is to be given, the same weight of the extract
very considerable, and as this consists of a stiff
a local reaction usually results. By repeated
ifications it is possible to obtain material of an
ivity between 1 and 2 mg. per unit, but even this
s not give by any means an ideal solution for
ections. Up to the present we have been unable
obtain oily material with an activity of below
ng. It can readily be seen that the very nature of
substance tends to inhibit its clinical use. Many
estigators have endeavoured to prepare the active
ostance in a form soluble in water.

The literature on this problem is so extensive that
letailed review cannot be given. I will therefore
rely mention one or two investigations.

Zondek and Aschheim[11] state that they could produce the hormone in a water-soluble form by boiling the oily material with acetic acid. Up to the present we have not succeeded in obtaining active material in this manner. Laqueur[12] and his co-workers in Amsterdam have published a very long series of papers in which they state that they have successfully elaborated a method for the preparation of the hormone in a water-soluble form. Again, the methods elaborated by Prof. Laqueur have not been very successful in our hands, but he has sent me material of high activity prepared by himself. At the Middlesex Hospital we have been working for some years now on this problem of preparing the ovarian hormone in a water-soluble form. Last year a method was elaborated by which the active principle was extracted from the placenta as a picrate which was subsequently converted to hydrochloride. This work[13] was published prior to Coward and Burn's observations on the standardisation, and a repetition of our work proved that the yields were very unsatisfactory and, in fact, that the method was unsuitable for general work.

A prolonged series of experiments with my colleagues, Dickens, Allan, and Howitt, showed that the hormone would resist boiling with baryta, and that from the baryta digest of the placenta the hormone could be recovered in a water-soluble form. The actual method of procedure is somewhat involved, and will only be dealt with in a very brief manner here.

The placenta is hydrolysed with baryta for a period of two hours by boiling in a flask fitted with a reflex condenser, and after allowing it to cool it is found that a precipitate has settled out and that a clear supernatant fluid is left. This is decanted and extracted with butyl alcohol. The extraction is performed fairly thoroughly in a shaker for a period of some hours. On allowing it to stand the emulsion separates immediately and the butyl alcohol is syphoned off. On evaporation a sticky residue is obtained which contains a part of the fats and soaps of the original placenta together with the hormone, but it is contaminated with large quantities of protein derivatives, such as peptones. The sticky material is dissolved up in water and the resultant solution is again extracted with ether in a separating funnel. The ethereal layer also separates quite readily on standing and is syphoned off and evaporated to dryness. This process completely removes the protein derivatives. A certain amount of nitrogen is still found in the material, but it has been found that this can be largely removed by shaking the ethereal solution with hydrochloric acid. The residue from the ethereal solution is heated with a small quantity of baryta in order to render the saponification complete. The precipitate of the barium soaps is filtered off; the excess of barium in the filtrate is precipitated by the addition of dilute sulphuric acid. The final solution is water-clear and possesses the property of producing œstrus in very high dilutions. Full details will be published later.

As will be gathered, this process has been elaborated as the result of a long series of experiments. Each stage has had to be checked by standardisation. A very curious, and at the same time misleading, phenomenon was encountered in the early stages of this work; it was found that a considerable yield of crude water-soluble material was obtained after the first baryta digestion; that is to say, this material, when freed from excess barium and injected into rats in one dose, was found to give a full œstral response, and could be standardised in the manner described by Coward and Burn. When, however, this material was subjected to a series of processes which, one had every reason to believe would lead to purification, it was found that the potency had diminished. We concluded that our methods of treatment had destroyed the active principle or reduced its potency, but, again, a long series of exhaustive experiments proved that this was not the case. It was found that the falling off of the potency was due to the fact that the material, when injected in one dose, was inactive, but when the same quantity was given in a series of injections spread over three days a full œstral cycle was induced.

A typical experiment on these lines is as follows:—

A preparation was given to 20 rats in single doses of 0·7 mg., and it was found that none of the animals went

into œstrus. According to the scheme which we have already outlined, this preparation was recorded as being completely inactive. When, however, another batch of 50 animals was injected morning and evening for three days with 0·026 mg. in all, a full œstral response was obtained in 25 of the animals, thus giving the correct percentage for the calculation of a unit. This remarkable result can only be explained by assuming that the active principle in this relatively pure water-soluble form is rapidly excreted, and that it is necessary to give a small number of injections in order to obtain the full response. This type of experiment has been performed so many times in my department that it leaves us in no doubt that the statement of Coward and Burn concerning the equality of effect of a single or multiple dose is wrong. It must, of course, be borne in mind that these observations were made entirely with a relatively crude oily material, the weight of the unit being somewhere about 10 mg. This material is absorbed slowly and will, therefore, imitate the effect of splitting up the dose. The weight of the unit of our material is somewhere about 0·02 mg., and a yield of some 150 to 200 units per kg. of placenta is constantly obtained. The preparation is without action on the blood pressure and does not give rise to local reactions when injected into animals. In fact, large doses seem to produce no ill-effects. It would appear, therefore, that this material is eminently suited to clinical investigations, and we are at present engaged in collecting a large stock of this preparation for clinical trial.

The Termination of Pregnancy.

Before leaving the purely experimental side of this question, there is one other very important pharmacological action of the extract, and that is its ability to terminate pregnancy in animals. This important action has been studied by Smith[14] in America, and by Parkes and Bellerby in this country. All these workers have proved that the injection of a fairly large number of units will cause abortion in laboratory animals. It is hardly worth while to consider the number of units required to produce this action, as this work was done prior to the publication of Coward and Burn's paper. We ourselves have repeated these observations and found that our own material will terminate pregnancy. My colleague, Dr. Allan, is at the moment trying to induce premature labour in laboratory animals by means of small graduated doses of the extract. By this means it is hoped to terminate the pregnancy and produce living offspring. If this problem could be worked out quantitatively there can be no doubt that its application to clinical medicine would prove of great value.

To summarise briefly the position of our knowledge of the ovarian hormone, we can say that we have a preparation that will produce œstrus in animals, and which can now be obtained in a form suitable for clinical investigation. The material will also produce abortion in animals.

Clinical Applications.

To many of us the clinical application of this substance is really the most important aspect of the whole problem. What clinical result do we hope to achieve by the use of this preparation? I suppose that one of the most useful outcomes of the work would be to start menstruation in women in whom this function was absent. The question arises as to whether we are justified in assuming that an extract capable of producing œstrus in an animal will produce menstruation in a woman. This immediately pitchforks us into one of the most difficult problems in biology—viz., to what does menstruation correspond in the lower animals? This, of course, is practically an unanswerable problem, there being so many theories supported by so much conflicting experimental evidence that it is not a subject for a biochemist to plunge into and give a brief summary of at the end of what has been meant to be mainly a chemical lecture. I will, however, attempt to summarise very briefly one or two of the existing theories. We must consider the various cycles that are going on in female animals. In the lower animals we have the œstral cycle, which we have described at some length, and we have, in addition, the ovulation cycle in which the ovary is discharging ova at certain definite intervals. In addition to this we have also the corpus luteum cycle, which is very short if pregnancy does not supervene. According to most observers, ovulation occurs in the majority of animals at some time during œstrus—that is to say, the rupture of the follicle, together with discharge of the ovum, takes place during each œstral cycle. Now in the case of the higher primates we have the same number of cycles, but in place of the œstral cycle we have, in addition, the menstrual cycle. To what does the periodic bleeding from the uterus correspond? And what relation does it bear to ovulation? The latter problem has in part been answered by the researches of Corner.[15] A careful study of the reproductive tract of monkeys revealed the degeneration ovum in the uterus which was in the later stages of the menstrual cycle. From this it would appear that ovulation occurs some time before menstruation. Now, since ovulation occurs in the lower animals during œstrus, it might be concluded that menstruation corresponds to œstrus, or in any case that the pre-menstrual period bore some relation to the post-œstral stage of other mammals. This, of course, is by no means a definitely established fact. According to Fraenkel,[16] menstruation is due entirely to the retrogression of the corpus luteum, and his work showed that when the uterine mucosa broke down he could always find degeneration of the corpus luteum in the ovary. He therefore regarded menstruation as a pathological process due to the destruction of the corpus luteum through pregnancy not supervening. As Corner puts it, "menstruation therefore (though by no means an abortion of the unfertilised ovum, as it is sometimes put) is merely a violent demolition of the pre-menstrual uterine edifice some days after the expected tenant fails to arrive." We can see, therefore, that the position may be summarised as follows.

Menstruation may correspond *(a)* to pro-œstrus, *(b)* to œstrus itself; *(c)* it may be a pathologic process according to Fraenkel; *(d)* it may have no relation whatever to ovulation. If we are to accept the teachings of Fraenkel, then we must conclude that menstruation bears only a very distant relationship to œstrus in the lower animals. We must, therefore, not be disappointed if we cannot produce menstruation with our œstrus-producing hormone. Many workers have, however, reported positive results. The difficulties with regard to local reactions when oily material is injected have already been pointed out. In any case it is impossible to consider the question from a quantitative point of view. Some workers have reported that menstruation could be induced in amenorrhœa by the injection of 1 or 2 rat units, whereas others state that 6000 units must be given to produce effect. It is obvious, therefore, that we should gain nothing by a consideration of this literature.

Conclusion.

In conclusion, we can say that the work of biologists, physiologists, and biochemists has handed to clinical medicine a preparation which is highly potent in animals. It will produce œstrus, cause growth enlargement of the genital tract, induce precocious puberty, and will cause abortion and possibly premature labour. It remains to be seen what this new substance will do in the clinic. Unfortunately, we cannot regard the clinical literature of the past as being of much value, and before any person experiments with the material on women patients he should be certain that the material has been carefully standardised on animals. The important point to remember is that we are just about to begin the clinical investigation of the ovarian hormone, and that we are not, as certain commercial publications would have us believe, just putting the finishing touches to a completed field.

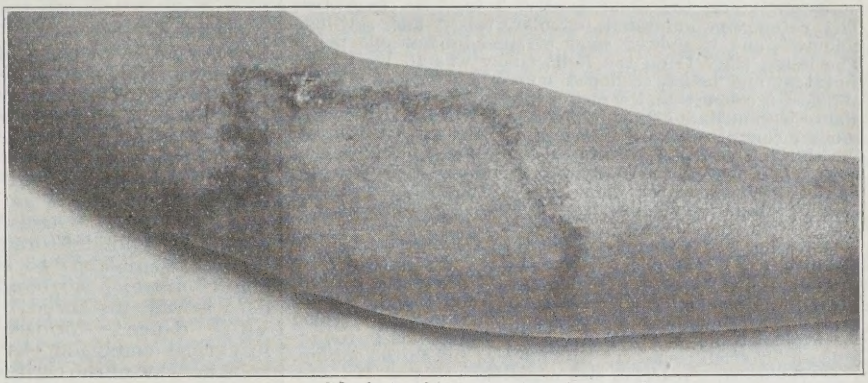
ON TWO APPARENT RECOVERIES FROM ANÆSTHETIC LEPROSY FOLLOWING PROTEIN SHOCK TREATMENT.

BY PHILIP MANSON-BAHR, D.S.O., M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON.

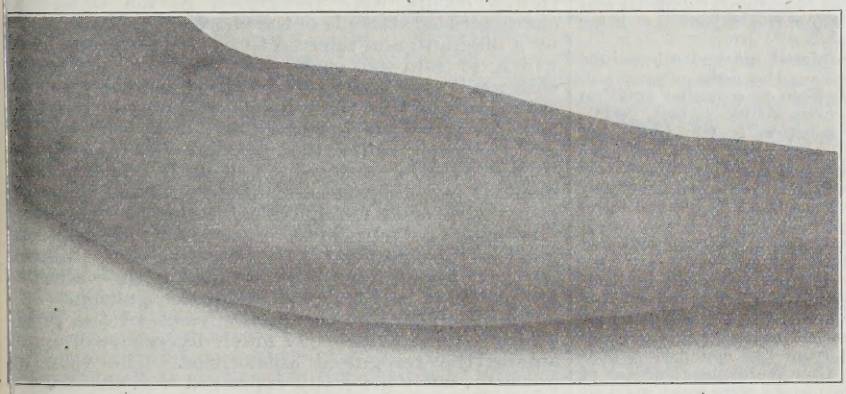
VERY striking improvements and remissions from all active leprous symptoms have been reported from time to time as a result of treatment with a variety of agents. Many successes from the injection of ethyl esters of chaulmoogra have been reported by Rogers and Muir.[1] These reports seem to justify the surmise that the agents which cause the most profound constitutional disturbances produce the best results on the more active symptoms of the disease. Somewhat similar results in nodular leprosy appear to have been obtained by the intramuscular or subcutaneous injection of irritating substances, such as turpentine, into the lesions; these are substances which primarily bring about severe local reactions. The intravenous injection of proteins, producing a generalised systemic reaction, was apparently first employed for leprosy by Hasson,[2] who reported successful and almost instantaneous results with intravenous injections of a vaccine consisting of 15,000 million killed *B. pyocyaneus* and 5000 million leprosy bacilli. The reactions caused by these injections appeared to be those of a severe "protein shock." In 1926 he reported a case of acute nodular leprosy originating in an oriental student who had been treated by this method with great and apparently lasting benefit; this improvement appears to have been maintained for over 18 months. Dr. N. A. Dyce Sharp,[3] from the Cameroons, has been able to record almost as favourable results from the intravenous injection of sterilised preserved milk—0·5 c.cm. in 5 c.cm. of water. A protein shock with severe reaction ensued and lasted several nights. There could be no doubt of the benefit to the patient. Relief from pain in joints and bones was obtained within 24 hours; perforating ulcers of the soles of the feet became painless and healed up in three or four days. The results were ascribable to the general tissue reaction consequent upon protein shock.

FIG. 1 (Case 2).



The lesion before treatment.

FIG. 2 (Case 2).



The arm, showing disappearance of the lesion after treatment.

In reporting the following cases of anæsthetic leprosy I wish to avoid using the word "cure" for what is, after all, an arrest of the tissue-destroying process. I do not claim that all the leprosy bacilli in the body have been destroyed. It is manifestly impossible to do this. In leprosy, above all diseases, it is extremely difficult to be sure that the favourable changes observed are permanent until a good many years have elapsed.

CASE 1.—An Eastern student; was first seen by me in October, 1925. He had lived in England two years and had been studying in London. In the middle of May, 1925, he found, quite by chance, a small discoloured whitish patch on his right knee. At first it was thought to be leucoderma, but subsequently it was found to be anæsthetic. The Wassermann reaction was negative. On careful examination there could be little doubt that this patch was one of anæsthetic leprosy. The margin was raised and slightly nodular, and was of a peculiar purplish colour. The macular patch measured exactly 3½ by 2½ cm, and in the centre was completely anæsthetic to pain and heat.

On Nov. 28th, 1925, a blister was raised by the application of Hasson's carbonic snow method, and in the centrifuged abstracted blister fluid it was possible to demonstrate numerous *B. leprœ*, thus clinching the diagnosis. On the same day treatment by intravenous injection of Hasson's vaccine was commenced. The result was to produce within an hour violent symptoms of protein shock. In all, six intravenous injections of vaccine were given within one week of each other, varying from ½ c.cm. to 1 c.cm. There was nothing in the subsequent reaction to distinguish it from ordinary protein shock. On June 19th, 1926, I found

that the area of anæsthesia had considerably diminished, and by August of that year he was able to feel light touch and heat over the whole of the previously anæsthetic area.

By Dec. 10th, 1926, all signs of leprotic infiltration at the margin had disappeared, leaving only a slight discoloured patch to mark the site of the former lesion. The patient was in good health and condition and had put on weight. The hairs were sprouting over the previously depilated area, and it certainly looked as if the leprous process had been arrested. The progress has since been maintained. He received no other form of treatment whatsoever.

CASE 2.—Also an Eastern student; after two years' residence in England developed anæsthetic leprosy of both arms. The history he gave was that, in May, 1926, a small red spot appeared on the flexor aspect of the left wrist and in June of that year a similar patch appeared on the right elbow. On both patches there was complete anæsthesia to pain and heat. The lesion on the left wrist was about 5 cm. in diameter, on the ulnar border, 2 in. from the wrist. The patch was indurated, circular, raised and raw-ham coloured, and it showed signs of spreading at one point. The lesion (Fig. 1) on the right elbow was 16 by 12 cm. in extent and had a scolloped border and raised margins of a deeper colour than the rest of the lesion. It showed faint nodosities and indurations along the border. Both lesions showed complete anæsthesia, loss of hair, and atrophy of the skin. There was definite thickening and induration of both ulnar nerves, especially the right, and this, together with anæsthesia of the ulnar side of the right hand and definite wasting of the interossei muscles, left no reasonable doubt of the diagnosis.

Unfortunately it was not possible to demonstrate leprosy bacilli either in the nasal mucus, in the blister fluid from the lesion, or in section of the skin taken from the margin. This, however, is by no means exceptional and did not invalidate the clinical diagnosis. Skin sections revealed the typical tissue changes of leprotic infiltration; round-celled infiltration round the hair follicles and in the corium. The Wassermann reaction was negative.

From the experience gained in the first case and from what appeared to be the direct effects of non-specific protein shock therapy, it was decided to administer "protein shock" by intravenous injections of T.A.B. (typhoid and paratyphoid vaccine) instead of by Hasson's specific vaccine. On Oct. 1st, 1926, treatment began with intravenous injection of 50 million T.A.B. The dose was gradually ncreased at weekly intervals up to 200 million organisms. As a rule the onset of the shock was considerably delayed and occurred from 4 to 12 hours after the injection. Four injections in all were given.

Soon after the course was completed marked alterations appeared in the anæsthetic patch on the right elbow, and since that time improvement has been progressive until no signs of the former lesions are now visible (April, 1928). Not only has the peculiar discoloration of the indurated skin completely disappeared, but sensibility of the affected area has entirely returned. There is no longer any anæsthesia of the right hand. The right arm (Fig. 2) is more muscularly developed and is actually larger than the left. There is no feebleness of grasp and the interossei are well developed. The hairs have grown on the anæsthetic patches and the skin looks perfectly normal. Both ulnar nerves are still thickened, but nerve sensibility is now produced in both arms by direct pressure on the nerve itself. The remarkable disappearance of all obvious lesions of the disease can best be judged from the illustrations. If more complete proof is necessary, it can be obtained from the coloured photograph taken and exhibited by the Wellcome Bureau of Scientific Research at the time the lesions were most marked and the patient was first seen. It would now be extremely difficult for anyone (one and a half year later) to ascertain whether the patient had ever suffered from leprotic symptoms. The nasal mucus remained free from leprosy bacilli during the whole period of observation.

As has been said, no attempt is being made to affirm that the patient is definitely "cured," but we can safely say that the disease process has been so arrested as to enable him to mix freely with his fellows.

I submit that these two examples of apparent recovery from leprosy are sufficiently striking to warrant record, and that the improvement in the patients' general condition and the restoration of the destroyed leprotic tissue and the return of sensibility are too apparent to be merely accidental. It is possible that beneficial results may not be obtained in every case of anæsthetic leprosy, but in early lesions protein shock treatment is certainly worth a trial.

THE DIFFERENTIATION OF HYPERKINESIS IN CHILDREN.

BY E. W. NEILL HOBHOUSE, D.M. OXF., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, ROYAL FREE HOSPITAL AND WEST END HOSPITAL FOR NERVOUS DISEASE; PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN.

CERTAIN aspects of hyperkinesis in children, suc as the nature of the neural disturbance in chorea an athetosis, have received the full degree of attentio which the importance and obscurity of the subjec might be expected to attract, and which is evidence by numerous and voluminous contributions to th literature of neurology and pædiatrics. In strikin contrast to this is the scanty attention which ha been devoted to the exact differential diagnosis, b clinical methods, of the various forms of hyperkinesi This problem has rarely been subjected to critica analysis as a whole; it is customary to find in on place a short discussion on the differences betwee habit-spasm and chorea, and in another betwee Sydenham's chorea and hysteria. The existence symptomatic chorea as a manifestation of cerebr disease is well recognised, but little prominence given to the possible difficulty which may be presente by its resemblance to the rheumatic variety. Th confusion which surrounded the subject from an earl date is well instanced by the use of the term "S Vitus' dance"—formerly descriptive of a pure hysterical condition—as a synonym of Sydenham chorea. One of the earliest attempts to place the stud of hyperkinesis on a scientific basis is found in D Francis Warner's lectures on the Anatomy of Mov ment [12] (1887), in which the view was first pr pounded that chorea was "a reversion to the infanti ratio of functions." The degree of classificatio accomplished by Warner was comparatively sma since but few of the conditions in which symptomat chorea occurs were recognised in his time. Th characteristic attitude of the choreic hand is illustrate by a diagram, and referred to as "the nervous hand which is said to occur in "nervous and chore children." Nevertheless to Warner belongs the cred of recognising that the subject could only be freed fro the obscurity which surrounded it by the adoptio of a strictly objective method of investigatio "Describing facts as we see them, in terms of mov ment, is probably the best mode of attempting to away with such metaphysical terms as 'voluntar 'intelligent,' 'purposive,' in scientific descriptions Much of the confusion in the literature of the followi 20 years might have been avoided if the validity this attitude had received earlier recognition.

The literature of the earlier years of the prese century shows evidence of much divergence of opini among the recognised authorities. The view w however, fairly generally expressed that the diagno of chorea was an easy one, and that, if chorea was t result of a cerebral lesion, evidence of this lesi would always be present. The prognosis of cereb lesions in children was then regarded with extre pessimism, and the remarkable degree of recove which is so often obtained in them does not appear have been anticipated. James Taylor,[13] howev explicitly recognises a type of case to which attenti is drawn in this paper, though he expresses no vie on the differential diagnosis. "Just as a condition f choreiform hemiparesis may develop upon the clearing up of an initial hemiplegia, so may a condition f generally distributed hemiathetosis develop in te absence of any great degree of paralysis or rigidity." Leonard Guthrie [10] (1907) states that the moveme s which follow infantile hemiplegia bear no resemblance to those of rheumatic chorea. He was among te first to draw attention to an important point in te differentiation of movements—i.e., the persistence f hyperkinesis after recovery from Sydenham's chor "though the child is in perfect health and can inhi t the movements by an effort of will. The chorea s

cured, but the symptoms still remain." For this state of affairs he proposed the term "residual chorea," but made no suggestions as to its exact nature. In Pfaundler and Schlossmann's Handbuch für Kinderheilkunde[14] (1908) Thiemich paid some attention to the differentiation of movements. The occurrence of chorea *instead of* muscular rigidity, as a result of "intra- and extra-uterine organic disease of the brain," is emphasised; it is stated that the primary disease is at once revealed by a systematic examination. He regards movements of a non-choreic type as more likely to present difficulty in diagnosis; "the muscular unrest and twitching movements indulged in by neuropathic children are more apt to be confounded with chorea minor, and this mistake is not uncommon in general medical practice." In a later edition of this work (1924) T. Gött describes the diagnosis of chorea as easy. He bases the distinction between true chorea and the "choreatic restlessness" of anxious and shy children on the hypotonus which accompanies the former. Bechterew,[17] writing in 1911, subscribes to the current opinion, and says that the diagnosis of chorea presents no difficulty. In the most comprehensive work which has been written on the nervous disorders of childhood, that of Bruns, Cramer, and Ziehen,[15] the differential diagnosis of Sydenham's chorea from other forms of chorea is almost entirely ignored; the persistence of movement after subsidence of the disease is mentioned. These authors regard the diagnosis between chorea and hysteria as difficult; the two signs upon which they place the most reliance are the hypotonus present in chorea and the diminution of movement in hysterical cases when the attention is diverted. Georg Peritz[16] (1912), though he summarised the diagnosis of chorea as comparatively easy, drew attention to the existence of difficulty in a proportion of cases. He considered that the movements observed in infantile cerebral palsies were indistinguishable from those of Sydenham's chorea. The diagnosis was to be established mainly by the age of onset, the movements of cerebral palsies being usually congenital or coming on during the first year; the accompanying signs of pyramidal involvement would also make the case clear. Nevertheless he admitted that some cases would only be made obvious by observing the course of the disease over a prolonged period. In Garrod, Batten, and Thursfield's Diseases of Children[18] (1913) Voelker states that the diagnosis of chorea rarely presents any difficulty, except in the paralytic form which may simulate a hemiplegia. He adds that "the movements of chorea are sometimes roughly simulated by those of hysteria, but the latter are without that incoördinate and unpurposive character seen in chorea." Batten, in the chapter on cerebral diplegia, describes an athetoid group, a choreic group, and a "perverse movement" group; in the latter group there is, as a rule, a good deal of alteration in the mental condition. He states that "the cases with choreic and perverse movements are, when first seen, difficult to distinguish from ordinary rheumatic chorea, and it is only by noting the persistence of the movements associated with the mental defect that a correct diagnosis can be made."

During the years immediately following the war the occurrence of symptomatic chorea in epidemic encephalitis was recorded by numerous observers in various countries, and rendered the exact diagnosis a matter of much greater urgency and importance. Prof. A. J. Hall[19] described the movements in one of his cases as being indistinguishable from those of Sydenham's chorea. He also drew attention to the close resemblance between the pathology of encephalitis and that of the fatal case of chorea described by Greenfield and Wolfsohn.[20] In recent years the incidence of acute encephalitis has fallen in proportion to that of the more insidious types, but the occurrence of chorea as an early and as a late symptom is universally recognised. There is evidence of a certain tendency not only to utilise the association with extrapyramidal syndromes for the purpose of drawing conclusions on the pathology of chorea, but to extend the speculation to other forms of movement. Bing,[21] on the ground of a supposed frequency of tics and similar movements among Parkinsonian patients, has been led to believe that many so-called "functional" forms of hyperkinesis are the result of disturbed function in the basal ganglia, for which he suggested the term "anisosthénie extrapyramidale passagère."

Reference is made later to the contributions to the literature made by Wall and Kinnier Wilson, as representative of current opinion at the present date.

Fidgetiness.

One of the most frequent causes of the temporary removal of a child from school is "fidgetiness." A large number of children exhibiting this symptom are sent to hospital for advice or treatment, very commonly with the history that the school doctor or the teacher said that the child had St. Vitus' dance. A reason for this, and an entirely legitimate one, is afforded by the widespread recognition of the fact that an early removal from school of all cases of true Sydenham's chorea is of the greatest importance in checking the course of the disease. In this form of hyperkinesis psycho-motor activities are in excess, and all sources of mental and physical stimulation should be diminished until the inflammatory condition in the cerebrum has subsided. Hence it has come to be regarded as a policy of safety to remove a child from school if it is fidgety.

In contrast with the degree of attention which has been accorded to chorea, other forms of hyperkinesis have received comparatively little serious investigation, especially when they occur in children who are sufficiently well to attend school and lead a normal life. A child who exhibits any fairly widespread hyperkinesis is likely to be diagnosed somewhat uncritically as chorea, and the assumption usually follows that the case is one of true Sydenham's or rheumatic chorea. It is no rare event to find that a patient of this kind has been put to bed for six weeks, in strict isolation, and that at the end of this period the fidgetiness is considerably increased, while the mental state gives evidence of the harmful effect of enforced inactivity on a child. Again, it is no rare event to meet with a child in whom the diagnosis of chorea has been made at frequent intervals over a considerable number of years, perhaps at every periodic school inspection, while the mother states that he has been more or less fidgety all his life. If a child of this type is not suffering from Sydenham's chorea the line of treatment indicated will usually be the direct opposite to that of chorea; it will consist in providing constant occupation and attempting to replace the "involuntary" and inappropriate movements by activities—motor and inhibitory—which are directed towards an end.

It appeared, therefore, that an attempt to differentiate as closely as possible the various types of hyperkinesis met with in children was desirable on practical grounds as well as those of academic interest, and for this reason all children brought to hospital for "fidgetiness," or in whose case any suggestion of chorea had been made by school or other authorities, were observed by the writer during a period of about 18 months.

The existing terminology is not favourable to the elucidation of the neural mechanism of hyperkinesis. In the first place, comparatively little attention has been paid to the non-choreic forms, their pathogenesis being obscured by the confusion inherent in the expressions "organic" and "functional." Secondly, the word chorea carries a double significance, well recognised in the literature, but not always borne in mind by the practitioner. This was clearly indicated by Wall[1] in his Bradshaw lecture: "chorea is a symptom resulting from disordered function rather than a single disease," whereas "we are justified in speaking of 'rheumatic chorea' as a disease." This attitude has probably never been challenged, and has subsequently received additional justification from the frequent occurrence of symptomatic chorea in children suffering from encephalitis. Nevertheless, one finds little evidence of it in medical teaching and practice, and, in the writer's opinion, failure to distinguish between

the symptom and the disease-entity has been a cause of much error in the diagnosis and treatment of hyperkinesis. The words "purposive" and "purposeless" have little objective significance, and tend to confuse rather than to clarify the differentiation of movements. Some of the difficulties inherent in the terms "voluntary" and "involuntary" have been pointed out by Kinnier Wilson,[2] who has shown that they merely express varying degrees of automaticity. They are especially inadequate for description of the movements now under examination, for a further reason. If subjective factors are taken into consideration it will be obvious that in many of these children the movements are not only "involuntary" in the sense of being automatic; they are "contra-voluntary," entirely beyond the control of volitional inhibition, and an evident source of distress to the child.

If these cases are considered from the standpoint of the neural mechanism underlying them they will be found to fall into two principal types: (1) Those in whom the superfluous movements are reproductions of movements which are normally carried out by the child under certain circumstances, and which (though it is certainly true that many of them have become to some extent automatic) have been developed by volition, or as reflex responses of the type which yield evidence of cortical influence. They are produced by *normal* motor activities, the abnormality being in their occurrence or frequency. (2) Those in whom the movements are atypical in character, or are reproductions, usually more or less distorted, of movements of emotional expression. These two types of movement exemplify, or rather caricature, the normal motor activity of the child and the infant. Nothing in any way resembling infantile movement will be seen in children of the first type, while those of the second type often appear to differ from it in degree rather than in kind. Location of cases of hyperkinesis into one of these two groups, as a preliminary measure, has many advantages over the use of a classification involving subjective factors, and can usually be accomplished without great difficulty by clinical observation. A striking difference may be noticed in the sex-incidence of these two groups. The first, in conformity with almost all types of nervous disorder in childhood, shows a marked preponderance of males (about 80 per cent. in the writer's experience). In the second group a large majority of girls will usually be found, owing to the high incidence of Sydenham's chorea in female children as compared with male.

TYPE I.—*Movements which are Reproductions of Normal Cortical Movements.*

These vary greatly in their situation and extent; the more simple ones yield fairly obvious evidence of their origin, and throw light on that of the others. They include cases described under a variety of names; when the movements are diffuse, extensive, varying from moment to moment, the child will merely be described as restless or fidgety, or, as frequently happens, be erroneously considered to be suffering from St. Vitus' dance. When the movements are circumscribed, single or few in number, and have become stereotyped by habit, they correspond to the types to which the terms tic and habit-spasm have been more or less indifferently applied. There is, however, no fundamental distinction between them, and their mode of origin is identical. They are reproductions of movements which have been evoked as a response (whether purely reflex or to some extent voluntary is immaterial) to some stimulus, and they have persisted in the absence of the stimulus. They are, in fact, of the nature of conditioned reflexes; their mode of origin was a purely physiological process, but the inhibitory processes which should have extinguished them were in default. Obvious examples will be found in the more simple "tics," as when a facial contortion, throwing back the head, wriggling the shoulders, or any other compound movement is repeatedly performed. In some the original stimulus is easy to determine, and takes the form of irritation from a collar-stud or ill-fitting garment; the unconditioned reflex was a defensive one. Equally obvious are the grunting movements which may persist after some irritation in the throat has been present. The restless or fidgety child who fiddles with objects or picks his clothes merely exemplifies similar processes which are manifested in greater number but to a lesser degree. He is constantly repeating movements which have on past occasions been directed towards an end, but whose repetition is now superfluous and inappropriate.

In normal circumstances conditioned reflexes are extinguished at some period after cessation of the conditioned stimulus, or are suppressed by the inhibitory effects of subsequent afferent impulses, superfluous pattern-reactions thus becoming eliminated. In hyperkinesis of this type the inhibitory influences are defective. The experimental work of Pavlov in animals has shown that the formation and disruption of conditioned reflexes is a function of the frontal lobes, and we may regard children who show these movements as individuals in whom the function of the frontal lobes is below the optimum. Krasnogorski,[3 4] in his research on conditioned reflexes in children, observed characteristic differences in the formation and subsequent disruption of these reflexes in various psychopathic types, such as epileptic, subthyroid, and spasmophilic. Movements of this kind are found to some extent in children who show no other abnormality, but they are especially common and persistent in those who give evidence of psychopathic heredity, or of the spasmophilic type of rickets. The general rule that a disturbance of nervous function in a child is of slight or serious import according to the age is particularly applicable to this form of neurosis. In children under six it may be regarded as a small and often transitory divergence from the normal, which will right itself if attention is directed to the occupations of the child. In children over ten years of age general fidgetiness in itself is almost always a sign of defective mental adjustment, and is of unfavourable prognostic significance, while systematised tics are usually associated with some of the other disturbances of habit-formation which compose the clinical picture of psychasthenia.

TYPE II.—*Movements which are Atypical in Character*

Movements usually classed as choreiform are the commonest of this type; others, such as athetosis and "spasmus mobilis," will be included. It has frequently been stated that each individual movement in chorea is a typical voluntary movement. This may be true, yet the total movement viewed in continuity is an entirely atypical performance. The essential difference between normal muscular activity and choreiform movement has been indicated by Kinnier Wilson,[2] who pointed out that Sherrington's law of reciprocal innervation no longer holds in the latter.

The exact situation of the neural disturbance which occasions this modification of motor activity still remains somewhat obscure, and it is sufficient here to refer briefly to some of the views most commonly held on this question. By analogy from certain chronic degenerative conditions such as Huntington's chorea and some types of choreo-athetosis, "athetosis double," &c., in which the lesions have been found to involve the basal ganglia to a greater extent than other parts (Levy,[5] the Vogts, and others) the situation in choreiform states has been conventionally located in these ganglia or their immediate connexions. One frequently expressed view is that choreiform movement is the result of "release" of extra-pyramidal neurones from the influence of the cortex, a reversion to the more primitive mechanisms of the infant. While this view does undoubtedly receive support from the resemblance between choreiform and infantile movements, its acceptance is rendered difficult by the cogency of the arguments submitted by Kinnier Wilson in favour of the relative integrity of cortico-spinal neurones in chorea. The balance of evidence seems to be in favour of his suggestion that cortico-spinal activity is unimpaired in as far as the hyperkinesis is concerned (in "paralytic" chorea it may also be affected), but is "released" from the influence

of afferent impulses from the basal ganglia and cerebellum. The changes found in the afferent cerebello-thalamic fibres by Bonhöffer [6] in some cases of "athetose double" lend support to this explanation.

Symptomatic chorea is met with in a variety of conditions apart from the rheumatic one. It occurs sometimes as an initial symptom, but more often as an early sequela, of epidemic encephalitis. It is often present, in association with other signs of neuronic disease, in a number of cases falling into ill-defined groups which are roughly classed as choreo-athetosis or "athetose double." In general, children of the latter types show athetoid as well as choreic movement, but it is commonly found that one form is replaced by the other after an interval of time. In a certain percentage of these cases the evidence of some cerebral lesion is unequivocal; there may be obvious spasm with reflex indication of pyramidal defect, as in many cases of double athetosis, or there may be some rigidity of muscles in a limb not affected by hyperkinesis, as in post-encephalitic syndromes. The existence of cases of this kind is well recognised, and the distinction between them and Sydenham's chorea presents no difficulty. A point with which the writer has been particularly impressed, both from personal observation and from study of published cases, is that in a large number of them the hyperkinesis is discontinuous and recurrent, and is not a constant concomitant of the spastic state. Temporary cessation of, or apparent recovery from, "chorea" is no valid reason for regarding the case as rheumatic.

The relative predominance of chorea and muscular spasm in cases of this kind is very variable. In many of them chorea is the only obvious symptom, the pyramidal tract having been but slightly affected, or having made a fair degree of recovery; nevertheless a careful examination of the nervous system will show that a residual pyramidal lesion exists. A child of this type (Cases 7, 8, 9, and 10) is liable to a diagnosis of "chorea" in which the symptom has not been sufficiently distinguished from the disease, and consequently to a course of extremely inappropriate treatment. If one of these children is observed over a number of years, it is usually found that the function of the pyramidal tract tends towards recovery; should the evidence of the residual lesion disappear altogether, the patient will merely present the clinical picture of symptomatic chorea. Cases of this kind, together with a number who may never have shown evidence of pyramidal defect, compose the type of chronic or recurrent chorea to which attention is especially drawn in this paper, with the suggestion that it may be more common than is usually supposed. In the majority of these children the hyperkinesis appears to have been first noticed in the second or third year. The resemblance which it bears to normal infantile movement is likely to prevent its recognition at an earlier age. In a certain number of them, however, some evidence of retarded development of motor functions will be obtained; when present this is of considerable diagnostic importance.

The cases recorded form links of a chain leading from obvious cerebral lesions, associated with chorea, to cases of pure symptomatic chorea, and indicate the existence of a class of choreas due to residual cerebral lesions. The pathogenesis of these cases is obscure, and is susceptible of the same variety of interpretation as that of cerebral diplegia, over which so much recent controversy has arisen. The work of P. Schwartz [7] has led many, who were inclined to attribute the cause of cerebral diplegia to prenatal factors, to the conclusion that the majority are the result of intracranial hæmorrhage during birth. The evidence which he brought forward is mainly drawn from autopsies on infants who were stillborn or who died shortly after birth; its application to infants who have survived is by inference, their symptoms being reasonably explained as the results of similar but less extensive lesions. According to Schwartz, the hæmorrhage by which these lesions are occasioned is not meningeal but intracerebral. It frequently takes the form of bilateral petechial hæmorrhages in tributaries of the vein of Galen, around which necrotic areas in the white matter subsequently develop. A common situation of the hæmorrhage was the vena terminalis; as a result of hæmorrhage from this vein necrotic areas were found in the basal ganglia, particularly in the head of the caudate nucleus. In many of the brains examined it was found that both types of lesion existed simultaneously. A number of pediatrists have attributed the cortico-spinal lesions in Little's disease to small hæmorrhages of this kind in the white matter. The lesions which would result from petechial hæmorrhages in the basal ganglia arising from the vena terminalis appear to offer an equally reasonable explanation of the incidence of some, at any rate, of the cases of residual hyperkinesis. The common, but inconstant, association of slight pyramidal lesions with hyperkinesis would be well explained by an ætiology of this kind.

Differential Diagnosis.

It is not possible in every case of symptomatic chorea to determine the exact nature of the disease at first sight. Instances will arise where it is advisable, while maintaining an open mind as to the precise diagnosis, to treat the case as one of Sydenham's chorea ad interim. There are certain points, however, which may be of great assistance in assessing the probabilities of the diagnosis.

(1) *History of Early Retardation.*—A large proportion of residual cases will give a history of delay in walking, talking, learning, &c., though this will not be obtained in post-encephalitic cases. The subjects of Sydenham's chorea tend to be of superior mental development, and a history of delay in reaching "milestones" should always raise doubts as to the presence of this condition.

(2) *History or evidence of rheumatic symptoms* is strongly in favour of Sydenham's chorea; no significance can be attached to their absence in an early case, as chorea may be the first rheumatic symptom.

(3) *Coexistence of athetoid movements* is sometimes observed in Sydenham's chorea, but it renders the diagnosis much less likely.

(4) (*a*) *Flaccidity of the hyperkinetic limb* and (*b*) *disturbances of the respiratory rhythm* are characteristics of Sydenham's chorea which do not appear to be simulated in the residual forms.

(*a*) In cases of "hemichorea," or of unequal distribution of the movements on the two sides, inequality of tone may also be observed. In Sydenham's chorea the limb most affected by the movements is very commonly hypotonic at some period of the illness, whereas hypertonicity of the affected limb, if it occurs, must be extremely rare. On the other hand, a combination of spasm and hyperkinesis in the same limb is a common feature of residual cases, while hypotonus is very unlikely, except in the presence of cerebellar symptoms.

(*b*) Czerny,[8] in 1916, drew attention to disturbance of respiratory rhythm, which he considered to be one of the earliest signs of chorea. According to his account a paradoxic movement of the diaphragm (ascent during inspiration), similar to that resulting from phrenic paralysis, occurs when the child makes voluntary deep inspirations. This paper seems to have received comparatively little notice, though occasional reference to "Czerny's sign" is found in the continental literature. O. Göttche,[9] in 1926, investigated this phenomenon with the aid of the X ray screen, and confirmed Czerny's observation that during natural quiet respiration the rhythm remained normal, but that if the child was made to take deep respirations certain changes in the rhythm took place. These were found to be of three kinds: (1) paradoxic movement, (2) immobility of the diaphragm, and (3) delayed movement of the diaphragm, which descended after the thoracic expansion was almost complete.

The respiratory rhythm has been investigated in all cases of hyperkinesis seen by the writer since the

appearance of Göttche's communication. Some disturbance of the coördination of thoracic and abdominal movements has been found in almost all well-marked cases of Sydenham's chorea, while it was never found in a child affected with habit-spasm or general fidgetiness. It was also absent in all cases of choreo-athetosis or other cerebral lesion, with the exception of one child suffering from post-encephalitic hyperpnœa. It is suggested that this sign may be one of considerable value in the differentiation of choreiform conditions, and that it deserves greater attention than it has as yet received in this country. Its utility is much increased by the fact that it is never likely to be reproduced in hysterical affections.

Mimeses.

A further complication in the differential diagnosis of choreic movements is provided by hysterical mimesis. Choreiform movement may be simulated somewhat closely, though probably not exactly, as a result of a mental process whereby the movements which a child has experienced or observed are reproduced in himself, usually—as in all hysterical manifestations—in pursuit of an unconscious end. This may take the form a heteromimesis in an otherwise healthy child, as in Case 11. Still greater difficulty is provided by an automimesis of a former attack, which may simulate a true relapse of Sydenham's chorea (Case 12). As in this case, the diagnosis may be revealed by the response to treatment, but the potential value of Czerny's sign is obvious. The question of hysterical automimesis must be considered in connexion with that of the persistence of choreiform movement after the subsidence of active disease, to which the late Dr. Leonard Guthrie [10] applied the term "residual chorea." In some cases this is probably accounted for by a true hysterical manifestation, an automimesis, replacing the original attack without any interval of recovery, occasioned by some unconscious desire such as to remain away from school. In the majority of cases it is likely that another process is responsible—i.e., that the pattern-reactions acquired during the illness continue to operate, new paths of lowered synaptic resistance having been developed *in the cortex* as the result of habit. Dr. T. C. Hempelmann [11] suggests that "in certain instances choreiform movements of the head and neck may become perpetuated as a habit-spasm." It seems legitimate to extend this conception somewhat, and to say that choreiform movement of any part of the body may become, after prolonged repetition, the mode of response which occurs as the result of recently conditioned reflexes. For practical purposes this process transfers the case from the second group which I have described into the first, and the treatment requires to be altered accordingly.

Summary.

Of the large number of children who exhibit some form of hyperkinesis a considerable proportion are not suffering from an active phase of Sydenham's chorea, and will be adversely affected by enforced inactivity or isolation. Insufficient recognition of this fact frequently leads to unnecessary removal of children from school.

Two principal types of hyperkinesis are to be distinguished from Sydenham's chorea: (1) non-choreic, including habit-spasm and general "fidgetiness," (2) choreiform, which are the result of some other condition (usually residual) or are hysterical in nature.

Symptomatic chorea may be the only persisting symptom of a residual cerebral lesion, as is shown by observation of cases in which the evidence of associated pyramidal defect has gradually disappeared. A possible relationship between some of these cases and the pathological conditions described by P. Schwartz is worthy of consideration.

The disturbance of respiratory rhythm described by Czerny is of value as evidence of an active phase of Sydenham's chorea.

Notes on Cases.

CASE 1.—Aged 8. Seen on May 22nd, 1926. Two weeks' history of fidgeting with right hand, but not using it. Movements of right hand were typically choreiform and the arm was hypotonic. There was irregularity of respiratory rhythm, not amounting to Czerny's sign. Was kept in bed; much improved on July 6th, 1926; recovered by August.

In July, 1927, he was brought up again with the complaint that the movements had started again; the question of his having St. Vitus' dance was being discussed at school. He was extremely fidgety, but the movements were not typically choreic. On being told to stop them at once he did so. The mother was assured that he had not got chorea and he returned to school.

Probably a case of Sydenham's chorea in 1926 and of hysterical automimesis in 1927.

CASE 2.—Aged 7½. Seen on April 27th, 1926. Fidgety for several months; does not use the right hand. Two years ago had "chorea" in the right hand. Growing pains. On examination choreiform movements were seen in all limbs, but were most marked on the left side. The right arm was hypotonic and exhibited very little voluntary movement. Treated by rest. When seen in July there was little hyperkinesis, but the right hand was hardly used at all. On August 27th recovery in both limbs seemed complete. An unusual case of Sydenham's chorea, which appeared to combine the features of "sthenic" and "asthenic" types (L. Guthrie) on the left and right sides respectively.

CASE 3.—Aged 10. Seen on June 22nd, 1926. Brought to hospital with the statement that she had chorea. Had fidgeted with the right hand and foot for five weeks. Involuntary movements, more or less choreiform but not typical, were present on the right side. The history showed that the mother had right hemichorea when pregnant; a playmate had right hemichorea a few months ago, and chorea seemed to be a frequent topic of conversation at home. The child was told that she had nothing the matter with her, and the mother persuaded to stop talking about it. The movements ceased during the next few days and did not recur.

A case of hysterical heteromimesis.

CASE 4.—Aged 11. Brought to hospital on Dec. 21st, 1926, with the history that during the last month he "fidgets the right arm and leg, but does not use them," and that "he has begun to stammer." In March of the same year "he fidgeted in all limbs," but had ceased to do so in May. Typical hemichorea on right side; right arm and leg hypotonic. Czerny's sign definite and persistent. Heart: Borderline enlargement with systolic murmur. Treated by complete rest; the movements gradually improved and had disappeared by February, 1927, but the stammer persisted.

A true relapse of Sydenham's chorea. A point of interest is raised by the possibility that the occurrence of the stammer may have been connected with the transition from the use of one hand to the other.

CASE 5.—Aged 4½. Seen on Jan. 30th, 1925. Symptoms: Twitching and picking movements of hands, irritable and emotional.

Signs: Incessant choreiform movement of both hands; fidgets with feet. No other abnormality in C.N.S. Heart normal.

History: In December, 1923, he had an illness in which the "left eye turned out." The movements began in 1924 and have been present from time to time since then. He does not get to sleep until 11 P.M., then sleeps for the whole night.

The movements began to improve during February. In March he was sleeping the whole night, and the movements were slight. During part of May he was drowsy in the day time. When last seen in July, 1925, the movements were those of a mild case of chorea.

A difficult case, in which the diagnosis between Sydenham's chorea and encephalitis could not be made with certainty.

CASE 6.—Aged 11. Seen on March 12th, 1926. Symptoms: Spills things, speaks indistinctly, makes faces, and his legs give way. He was said to have been normal in every way at the end of 1924; the movements began gradually soon after this. They often improved for a time, but never passed off. In 1925 he attended a nervous hospital, diagnosis "chorea."

Signs: Typical choreiform movements, not very severe. Muscle tone and reflexes normal. I regarded him as Sydenham's chorea and treated him accordingly. Six weeks later I noticed the boy dribbling, and was told that this sometimes happened, and that he had some difficulty in swallowing. Two weeks later there was slight but appreciable rigidity of the right arm, which did not swing when he walked.

A case of encephalitis in which symptomatic chorea was the only manifestation.

CASE 7.—Aged 6. Brought to hospital in July, 1927. Said to have St. Vitus' dance and taken away from school

light choreiform movements of both hands were seen, ather slower than usual and occasionally merging into thetoid movements. Reflexes and tone were normal; zerny negative. The condition resembled a mild attack of ydenham's chorea.

The child had attended me some years previously. From ie old notes it was found that she had been brought up in 923 (aged 2½) because she did not talk or use the right hand. had found slight spasticity of the right arm and leg, and ad diagnosed a residual birth hemiplegia. The left arm ad been tied up and recovery of function in the right arm ook place rapidly, being almost normal in July, 1924.

A case of symptomatic chorea in a child who suffered om a cerebral lesion. If the previous history had not been btainable she would probably have been regarded as ydenham's chorea.

CASE 8.—Aged 6. Admitted to the Victoria Hospital for hildren in March, 1924, under the care of Dr. R. C. ewesbury.

Symptoms: Fidgets with the left arm and leg, is twitchy," and uses the left hand very little.

Signs: The left hand was held in a peculiar position with ie thumb adducted. Sudden twitchings of the left arm id leg were observed. There was slight dragging of the ft leg on walking fast. The movements were more or less oreiform, but not absolutely typical. There was slight it definite increase of tone on the left side. Deep reflexes ere usually increased on the left side, but the hyperkinesis ade an accurate comparison difficult.

I considered the child to have a defect of the pyramidal act and the corpus striatum or its central connexions. ight is thrown on this case by the previous and the subseient histories.

Previous history: Had been an in-patient under Dr. ewesbury in 1923 (aged 3). Symptoms: Twitching of face, ovements of left arm, turning up of left eye; present for ur months, getting worse. Signs: Walked unsteadily, ckward in talking; weakness of left arm, leg, and internal ctus.

Subsequent history: The right arm was tied up during rt of the day and the child began to use the left hand much tter. She was, however, readmitted in September, 1925, ving been diagnosed elsewhere as chorea. The twitching the left side was worse; there was very definite increase tone and deep reflexes in the left arm and slight increase the left leg. Plantars: Flexor right, indeterminate robably extensor) left.

This case seems to provide an undoubted example of mptomatic chorea, in association with a cerebral lesion hich was either residual or so slowly progressive that its istence might escape notice even at the age of 8. I am uch indebted to Dr. Jewesbury for kindly allowing me to amine and record this case.

CASE 9.—Aged 7. Was brought to the West End Hospital a case of ? chorea, and admitted under the care of Dr. . R. Reynell, by whose kind permission I examined him d am including him in this series.

Symptoms: Movements of face and of all limbs, most arked on the right side.

History: No evidence of retardation, but has had movenents of this kind since infancy.

Signs: The movements were typically choreic, and on perficial examination the boy resembled a case of denham's chorea. There was slight internal strabismus. odominal reflexes left brisker than right, knee- and ankleks right brisker than left. Plantars: Definite flexor left; riable, usually atypical flexor right. There was some akness of the right arm; no increase of tone could tually be appreciated, but it swung less than the left nen he walked. Czerny negative. No evidence of eumatism.

A case of symptomatic chorea resulting from a residual rebral lesion.

CASE 10.—Aged 5¾. Brought to hospital in February, 26, for weakness of legs and movements of arms; had en sent away from school as chorea. History: Details delivery were not obtainable, except that he was "born ie with the cord twisted round his neck." He had peared to the parents to be normal during infancy, but uld not sit up alone until he was 1½. Talked well at 2. id been fidgety all his life.

Signs: Typical choreiform movement of all limbs, which times became more slow than usual; when lying quietly bed they were occasionally athetoid in type. Abdominal lexes absent. Deep reflexes unreliable owing to the ovements, but usually more brisk on the left side. There s a slight degree of spasm in the left calf, and he usually lked with the heel off the ground, but could get it down nen told to. Plantars: Flexor right, extensor left. The rebro-spinal fluid showed no abnormality.

He improved quickly in hospital and was obviously much tter when actively occupied. On discharge he went back to school. In December, 1926, movements were still present, the abdominal reflexes were just obtained, spasm of the calf was barely appreciable, and the left plantar reflex was indefinite. Czerny's sign was absent. Had he been examined first at this time there would have been little evidence of the pyramidal lesion. He was last seen on July 8th, 1927. He was still rather fidgety and the movements were roughly choreiform; no athetosis was seen. The reflexes were absolutely normal. He now presents the features of a mild symptomatic chorea, the diagnosis from Sydenham's chorea depending entirely on knowledge of the former physical signs.

A case of residual chorea or choreoathetosis (? birth hæmorrhage) associated with a pyramidal defect which recovered.

CASE 11.—Aged 9. The elder brother of Case 10. Had no symptoms until 1926. A few weeks after Case 10 returned home from hospital this patient began to fidget all over and speak less distinctly. He continued to go to school and did his work quite well. In October, 1926, he was brought to me because the school authorities said that he had chorea and should not attend.

Signs: Generalised hyperkinesis, not very severe; choreiform, but not absolutely typical; no abnormality of attitude. Czerny negative. The movements ceased when his attention was fixed on something else, and returned afterwards. He appeared to be much disappointed at being told that he had not got his brother's complaint and need not come into hospital, but must stop fidgeting. He returned to school, the movements ceased almost immediately and had not returned when he was seen in December, 1926.

An hysterical mimesis of the brother's condition.

CASE 12.—Aged 10. Brought to the West End Hospital on Feb. 8th, 1927, suffering from acute generalised choreiform movements, so violent that detailed examination was impossible. She appeared distressed and excited. The child had been an in-patient in a general hospital for two months in the previous autumn, suffering from chorea. She had been normal on discharge and remained so until the day before she was brought up to me, when a sudden return of movements took place. I regarded her as a relapse of Sydenham's chorea and recommended her for admission. Three days later she walked quietly into hospital with no sign of hyperkinesis or other abnormality. When I saw her next day she lay quietly in bed and could be examined with ease. She was made to get up and run round the ward; neither this nor any other activity led to any return of the movements.

Her condition appears to have been an hysterical automimesis of her previous attack of Sydenham's chorea, simulating a relapse. In recommending her for admission I had fulfilled the child's unconscious desire and cured the neurosis.

THE SURGICAL SIGNIFICANCE OF CORPULENCE.

By R. J. McNEILL LOVE, M.S. Lond., F.R.C.S. Eng.,
LATE SURGICAL ASSISTANT, LONDON HOSPITAL; SURGEON TO THE MILDMAY HOSPITAL;
AND
W. F. CHRISTIE, M.D. Edin.

ADIPOSITY of simple or exogenous origin, being an aberrant nutritional state rather than a physical disease, is encountered quite as often in the practice of surgery as in the sphere of medicine. It is always the result of faulty feeding over a long period of time, but it can be cured by dieting. While the management of "thinning cures" must rest primarily with the dietitian, the penalties of being too fat and the results which may be expected from a course of weight reduction are of considerable moment to the surgeon.

Life assurance companies are continually preaching to the public the serious menace to health of over-nutrition. Their opinion is based partly on physicians' reports, partly on statistical evidence. From the purely surgical point of view, not half enough has ever been said against corpulency. Unnecessary and preventable, it creates disease, obscures diagnostic signs, influences operative technique, and detracts from an otherwise good prognosis.

Surgical Conditions Depending on an Obese State.

These may be classified according to their mode of origin, static, mechanical, and metabolic.

Static Effects.—One effect of carrying about a burden of dead weight on the body is to strain its weight-bearing structures. For instance, a certain degree of lordosis is necessary in order to compensate for the pendulous abdomen and so an excessive strain falls on the sacro-iliac joints. Many stout women complaining of an aching pain in the lower part of the back from this cause, especially severe after standing or walking, are referred to the gynæcologist for elucidation. Osteo-arthritis of hips and knees is a common companion of old age, being due to a gradual degeneration within the joint. The increased strain imposed by excessive weight-carrying precipitates the onset of this condition. It is widely recognised that flat feet are prone to occur with the advent of the menopause, a time when figures are notoriously apt to spread; indeed, obesity predisposes to flat feet at any age. The orthopædist sees many of these cases.

Mechanical Effects.—When an excess of fat is present in the body, although the bulk is contained in the subcutaneous tissues, omentum, and other of the large depôts, it will be found that a certain amount has infiltrated the muscles. This infiltration impairs muscular efficiency, the impairment being noticed first where strain is greatest; thus obesity predisposes to herniæ. Indirect inguinal hernia can only occur, of course, if a congenital sac is already present, but the direct or acquired type is commonly associated with fatty infiltration of the muscles and resulting "flabbiness." The umbilical hernia of adults furnishes another example; fat from the extraperitoneal cellular tissue protrudes through the stretched and weakened linea alba, eventually being followed by a dimple of peritoneum. Increase of intra-abdominal pressure, consequent on the deposition of more fat in the omentum, and mesentery, causes the hernia to enlarge progressively. Diverticulitis of the colon, also, is predisposed to by fatty infiltration and consequent weakness of the bowel wall, although the false hernial protrusion of mucosa may be difficult to demonstrate in the overladen appendices epiploicæ.

Metabolic Effects are not fully understood but, in some cases, obesity is associated with a diminution in rate of the metabolic processes. There is some evidence to show that the cholesterol content of the blood is greater in fat than in normal people, which may be the explanation of the higher incidence of gall-stones in the former; another factor which predisposes to cholelithiasis is the lethargy associated with the obese state. Again, acute pancreatitis occurs most frequently in fat subjects, although the reason for this association is obscure. The inter-relationship between obesity and the ductless glands may be mentioned in passing, particularly noticeable after the operation of double oöphorectomy. Freed by surgery from the dangers of ovarian disease, the development of corpulence at a later date with all its attendant misfortune is the rule. Conversely, sterility without other cause is not uncommon in the over-nourished; reduction of weight, not insufflation of the Fallopian tubes, is the more likely to effect the cure.

Obesity as a Factor in Obscuring Diagnosis.

Every clinician has felt, at times, the hopelessness of adequate palpation when confronted with an enormous jelly-like abdomen. Enlarged viscera and tumours can lie completely buried, while even in such conditions as acute appendicitis it may be almost impossible to detect muscular defence or feel an abscess. Percussion through some inches of fat is non-informing and sometimes misleading; we have seen a normal chest needled for fluid owing to impairment of resonance from this superficial cause. Pelvic examinations are rendered much more difficult; sometimes it is impossible to palpate the uterus. A lump in an adipose breast may be so masked that it remains a mere lump with no characteristics upon which to base a diagnosis.

The radiologist also has his difficulties, many an otherwise passable film being reduced to obscurity on account of fat limiting the penetration of the rays.

Influence of Obesity on Operative Technique.

A serious problem in connexion with operation on obese subjects is that of anæsthesia. The thick neck renders maintenance of an efficient airway difficult, and the fatty heart predisposes to cardiac failure. Owing to the relatively poor blood-supply to adipose tissue, local anæsthesia is unsatisfactory in that it predisposes to necrosis and consequent infection. In gall-bladder cases, a cholecystectomy of average difficulty may become a most formidable undertaking. Owing to the depth at which the surgeon has to work, blunt dissection is apt to degenerate into blind dissection, ligatures are tied under difficulty and perhaps insecurely, whilst accurate insertion of deep stitches may be impossible. The discriminating surgeon realises these handicaps and may therefore rest content with the palliative operation of removal of the stones and drainage of the gall-bladder.

The abdomino-perineal removal of the rectum furnishes another trite example, careful dissection in the floor of the pelvis in a fat male requiring the maximum amount of self-control, skill, and dexterity. In fact, the penalty of obesity in connexion with abdominal operations is a very definitely increased operative mortality, or a palliative instead of a curative operation.

The convalescence of stout patients is often prolonged as a result of delay in the healing of their wounds. In them fat oozes from the cut surfaces, the resulting combination of blood and liquid fat forming an excellent culture medium for the growth of bacteria. The edges of wounds made through fatty parietes should always be approximated with deep sutures, while a drain at each end encourages healing by first intention.

Prognosis after Operations on the Obese.

From the nursing point of view, 18 or 20 stone of helpless humanity may cause the stoutest heart to quail. The difficulty of lifting and turning such a patient, if the available staff is inadequate, reacts very unfavourably on convalescence. If the weather be hot, these invalids suffer from it more than ordinarily. Death from heat-stroke while swathed in cotton-wool and a large abdominal or breast

andage is not unknown even in this country. The evelopment of broncho-pneumonia, especially fre-uent after the administration of ether, adds to he nursing difficulties; yet one dreads to use chloro-orm in these cases on account of the tendency to cidosis. Post-operative lung complications should e anticipated by propping up the patient in bed s soon after operation as possible, using artificial ieans of keeping him there. The exhibition of timulants and stimulating expectorants before they ppear to be necessary is a sound prophylactic ieasure.

The effect of obesity on the late results of operative rocedures varies with the disease. In one situation n excess of fat is sometimes welcomed by the irgeon—namely, the breast. Excision for carcinoma rendered easier in proportion to the plumpness of ie patient; moreover, the greater the amount of it, the wider is supposed to be the margin of safety. his advantage, if so it be, is somewhat neutralised y the additional difficulty of diagnosis. Percival ills noted in a series of cases that only 11 per cent. f the obese, as compared with 66 per cent. of the ormally proportioned, were "well" six years after peration. Late diagnosis, so fatal in carcinoma, robably accounts for the difference. By the time iat a stout woman feels a cancerous lump in her reast, the early stage of the disease is likely to have assed.

These few observations on the surgical disadvantages f the portly figure are worthy of reflection. Many iore could be recorded without encroaching on its urely medical aspects, although the two are usually ombined in the same person. The material for a ampaign against corpulence is ample and convincing. n cases of emergency, the surgeon must make the est of a severe handicap; but in after-care, as well s in less urgent cases, an insistence on careful weight eduction has much to commend it.

Weight Reduction from the Surgical View-point.

Since fat comes from food, surplus fat must owe its rigin to the same source. The cure, therefore, of ver-nourishment is under-feeding. A short review f the results which can be anticipated from reducing iets is interesting and instructive. Fat can be emoved quickly or slowly, in lesser or greater mounts. The practical utility of the methods may e seen from the following summary.

Rapid Methods.

	Expected *total* loss of fat in lbs.
Fasting, seven days, except for water ..	5 to 6
Fasting, 14 days, except for small amounts of protein	8 to 10
Greatly restricted diets—e.g., 21 days on "milk and potato cure"	

Slow Methods.

	Expected *weekly* loss of fat.
Restriction of fats and carbohydrates, slight increase of protein, great increase of roughage, over a long time	2 lb.

The difference between the two groups is similar o that which distinguished the hare from the tortoise the fable. Rapid reduction methods show a poor turn for all their violence of speed. A loss of to 10 lb. of fat is seldom sufficient to effect a cure, hile the personal effort required to obtain even iat amount is great. Sometimes, as when obesity id high blood pressure are associated, a speedy eduction is imperative, but muscular weakness and ie effects of acidosis may need to be combated. hese are the two chief dangers.

The slow reduction plan, therefore, is more generally pplicable; it is safe, it is sure, for 99 per cent. of ie people who pursue it will become thin; the ffects are permanent, since it teaches the reducer o avoid for all time the fat-forming elements in the iet. By removing 2 lb. every week or 20 lb. in n weeks, repeating the course as necessary, the ost ample of adipose coverings will disappear. It is important for surgeons, however, to understand the conditions under which satisfactory slow reduction can be attained.

The corpulent as a class love their meals, whatever they may declare to the contrary. Their endocrine glands may not be so active as those of thinner people, but the real basic cause of their adipose state is an indulgence, past or present, in the fat-forming articles of food. To hand to such as these a diet-sheet with the simple instruction "go hence and become thin," is quite useless; without personal encouragement and detailed dietetic guidance they will remain for a certainty adipose and inoperable to the end.

The first requisite for success, therefore, is time and patience on the part of the dietitian, as well as the will to conquer in the patient himself. By strengthening the latter, the surgeon is indispensable, but the actual dieting of these cases can be left quite well to a junior on his staff, whose whole-hearted interest and coöperation is assured. It is he, then, who should see that the reducing diet is suitable and properly applied, but the surgeon must retain the right of determining the amount of fat to be removed and in some cases, too, the rate of loss. The effectiveness of the dietetic prescription under such conditions of team-work is exemplified in the following case:—

Mrs. R. suffered from a small umbilical hernia, which was deemed inoperable on account of her adipose state. After losing 3 st. of fat by means of dieting, she was returned to the surgeon for operation; he requested, however, that another 2 st. should be removed before he would operate, making 5 in all.

The second requisite for successful weight reduction is the adoption of a scheme of dieting which can be adjusted easily to the particular requirements of the patient. By altering the quality of the food which is eaten, balancing the items and counting the calories, the fat person will lose his corpulence, but in so doing he need not be deprived of all the things he likes, nor made to eat all those which he never cared for.

The happiest results are obtained by building the diet to the individual in accordance with his food fancies and bodily requirements, rather a difficult task for any other than the professional dietitian. In most instances it will suffice for the house surgeon or family physician to prescribe a ready-made "skeleton diet"[1] worth about 1200 calories; this contains all those elements which are needed for the maintenance of health and the repair of tissue. If, while living on it, the patient loses more than 2 lb. a week, he may choose what he pleases from a "graded list of foodstuffs"[1] the extra quantity being limited to 100 calories a day; again the effect is noted after seven days, additions or subtractions being made accordingly. Every ten weeks a fortnight's respite from the strict régime should be granted.

Knowing the amount of fat to be lost, the surgeon can almost fix the date for his operation in advance. A steady loss of a stone and a half every three months is an average rate of progress; six stones need a year. There seems no limit to the amount of fat which can be removed. After emergency operations on the obese, the reducing diet can be commenced on the same day as the stitches are removed; the skeleton contains a sufficiency of vitamin C in the form of fresh fruits and green vegetables to ensure firm healing of the wound. Convalescence is too often regarded as a period for feeding up, whereas with stout people it should be used to inaugurate the process of thinning down.

In view of the penalties of corpulence and the comparative ease with which it can be reduced, it is incumbent on surgeons to keep in touch with over-nourished patients during their efforts to become thinner; in this way, fewer would suffer from surgical ailments or would be excluded from the benefits of surgery.

[1] Details of a skeleton diet with a graded list of foodstuffs appears in the Practitioner, May, 1928, by one of the authors.

THE INFLUENCE OF ULTRA-VIOLET RAYS ON INDUSTRIAL OUTPUT.

BY A. LISLE PUNCH, M.B., M.R.C.P. LOND.,
AND
RUSSELL WILKINSON, M.V.O., M.R.C.S. ENG.

With the collaboration of

R. STC. BROOKE, M.A.,
AND
C. S. MYERS, C.B.E., M.D., F.R.S.

DURING October, November, and December, 1925, an investigation was conducted into the influence of ultra-violet rays on the output of girls engaged in the manufacture of chocolates in the works of Messrs. J. Lyons and Co., Ltd., at Greenford, Middlesex. The treatment was applied by Dr. Lisle Punch and Dr. Russell Wilkinson. The data of output were obtained by Mr. R. StC. Brooke, psychologist to the firm. The general planning and supervision of the investigation and the preparation of most of the following report were the work of Dr. C. S. Myers, aided by a grant to the National Institute of Industrial Psychology from the Laura Spelman Rockefeller Memorial. The investigators are indebted to Mr. Julius Salmon, one of the directors of the firm, for the interest which he showed in the experiment and for the facilities which he gave for its smooth conduct, and to the British Hanovia Company for the loan of the necessary apparatus.

Twelve women employees of the firm, engaged in the manufacture of chocolates, volunteered for the experiment. This was divided into three observation periods: (*a*) a "pre-treatment" period of two weeks, (*b*) a "treatment" period of four weeks, (*c*) a "post-treatment" period of two weeks. Each girl was engaged throughout the entire experiment in making one and the same kind of chocolate, but the work of each differed in detail from that of her colleagues. The data of the output of each of the 12 girls were collected hourly throughout each of the three periods of observation. Three of the girls served as a control group. They believed that they were being given ultra-violet ray treatment, whereas in fact the ultra-violet rays were screened from them. Of the other nine girls one fell ill and was away from work for 17 days after three days' data had been collected from her during the pre-treatment period. Her records have therefore been omitted.

Treatment was given daily at 8 A.M. for four weeks. Of the 12 treatments the first four were on consecutive days, while in the second week three treatments, in the third week three treatments, and in the fourth week two treatments were given to each girl. Exactly the same procedure was carried out on the controls. The initial exposure was two and a half minutes for the whole body, back and front. Thereafter the exposures were increased gradually up to thirty minutes, according to the degree of erythema produced in each case. For the first four exposures each patient was treated individually with the air-cooled mercury-vapour lamp. Subsequently the girls were treated in batches of three at a time with the Jesionek lamps. The same lamps were used for the control group, but a sheet of "triplex" glass, 5/32 in. in thickness, was placed as a screen between the patient and the quartz burner. The absorption limit of this glass at this thickness being 3300, all the ultra-violet rays were cut off and no rays of shorter wave-length than 400 mm. reached the patient.

The findings had to be adjusted owing to the following circumstances: (1) During the pre-treatment and post-treatment periods of observation, the girls worked daily from 8 A.M. to 5.30 P.M. (with an hour off for dinner between noon and 1 P.M.); during the treatment period they began work at 9 A.M., as they were under treatment each morning between 8 and 9 o'clock. (2) At the start of each morning and afternoon spell of work the chocolate had to be tempered, so that the actual manufacture did not begin until 10 or 15 minutes later. (3) A rest pause of about four minutes was given during each spell of work. (4) A period of clearing-up occurred towards the end of each spell.* (5) Temporary absences from the room or from the works had to be allowed for.

* For this and other reasons the output during the last half hour of the day is not reliable; no records were therefore taken between 5 and 5.30 P.M.

The eight girls subjected to the ultra-violet rays whose individual output throughout the three periods was regularly recorded, will be designated respectively by the letters A–H. They fall into two groups: (1) those whose output was evidently increased (A, B, C, D) upon exposure to ultra-violet rays and (2) those whose output showed no change (E) or whose output was reduced (F, G, H) as the result

TABLE I.

—	Pre-treatment.	Treatment.	Post-treatment
A	96·6	90·0, 97·4 } 93·7	108·0
B	110·2	107·6, 108·9 } 108·2	117·0
C	103·7	110·0, 107·4 } 108·7	107·6
D	117·8	120·7, 119·1 } 119·9	122·0

of the treatment. Of the latter group, it is noteworthy that H gave no reaction at all to the rays while E gave a fair reaction, and F and G gave only average reactions. On the other hand, of the group that responded favourably to the treatment, A, B and C gave extremely good reactions to the rays while D gave a fair reaction. Table I. gives the average daily output in pounds per worker per fortnight. The total output of this group during the post-treatment period is thus 6·14 per cent. greater than during the pre-treatment period. The figure for A reaches 11·8 per cent.

The Subject's Own Statements.

The girls' own statements about the results of treatment are interesting. A said that she felt better and wanted more of the rays. B was most

TABLE II.

Pre-treatment.	Treatment.	Post-treatment.
1st week .. 87·5	3rd week .. 90·25	7th week .. 92·75
2nd ,, .. 93·75	4th ,, .. 94·25	8th ,, .. 87·25
—	5th ,, .. 92·25	—
—	6th ,, .. 91·00	—

enthusiastic; she found that she had more energy and that she could settle down more easily to her work. She also asked for a further course of treatment. C declared that she had slept better and that

TABLE III.

—	Pre-treatment.	Treatment.	Post-treatment
F	90·9	85·7, 83·7 } 84·7	84·0
G	73·5	71·15, 68·25 } 69·7	69·0
H	86·4	82·6, 79·2 } 80·9	84·1

her appetite had improved during treatment, but that she felt tired after it had ceased. D said that she felt distinctly better and wanted more. E, whose output gave no evidence of being affected by the

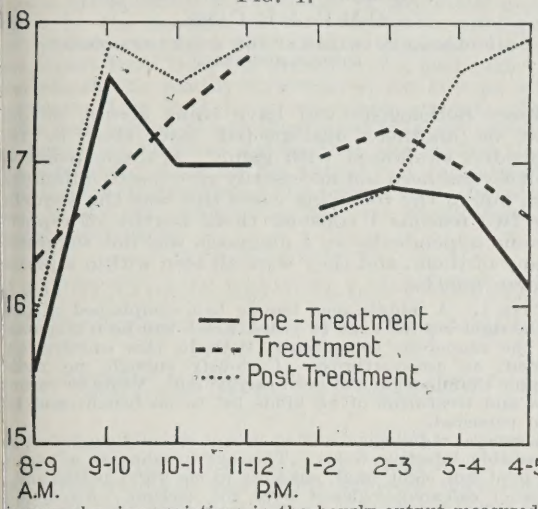
TABLE IV.

—	Pre-treatment.	Treatment.	Post-treatment
I	60·1	63·2, 65·4 } 64·3	63·9
J	56·2	56·7, 58·9 } 57·8	56·0
K	99·5	98·0, 103·9 } 100·9	101·7

rays, said nevertheless that her "nerves were better" after the treatment. But her output showed such wide fluctuations from week to week (as shown by the following data of average daily output) (Table II.) that no conclusions can be drawn.

F, a highly neurotic girl who was reported as difficult" and unreliable, declared that she felt no etter after the treatment; G was suffering from a old both before and during treatment; H, who ailed to give any cutaneous reaction to the rays, aid that she felt no benefit. Table III. gives the

FIG. 1.

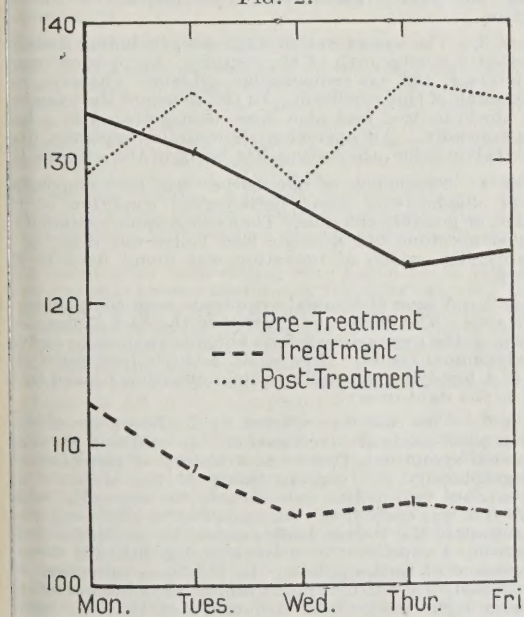


iagram showing variations in the hourly output measured in pounds. (Worker D.)

verage daily output of these girls per fortnight for ie three periods.

The three girls of group (3), the control group, ill be styled I, J, K. "I" claimed to feel better, it only while she was subject to "treatment"; er output improved correspondingly during that eriod, but fell off later. J felt little or no difference

FIG. 2.



ariations in the daily output, of Worker B, measured in pounds. The "treatment" curve represents the output of a working day of *seven* hours, whereas in the other two curves an *eight* hour day is worked.

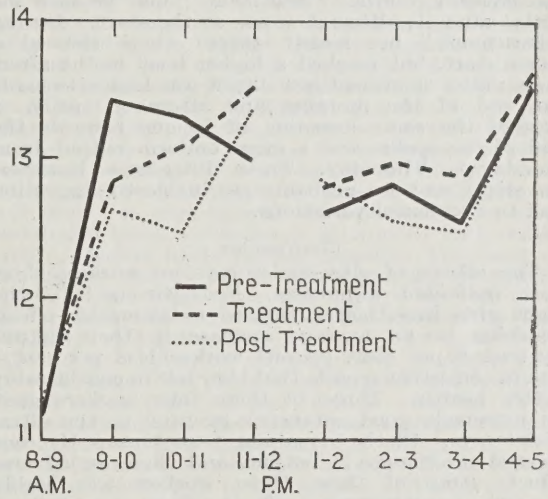
id showed practically none in her output. K, escribed as an excitable girl, fancied that she felt etter for the treatment and showed a slight, but idely fluctuating, improvement, her average daily itput during successive weeks being 98·75, 100·25, 5, 101, 106·25, 101·5, 100·5, 103. Table IV. gives ie comparable data obtained for this group.

Any real improvements in the output of the girls of this group may be ascribed: (1) to suggestion, which was probably operative in I and K; (2) to the beneficial effect of other rays—e.g., infra-red rays, to which this group was daily subjected during the period of the "treatment"; (3) to practice. Mr. Brooke wishes to point out that an expert worker like J would not have had much recent experience of the particular "line" on which she was engaged throughout the experiment, but as her progressive rise in output was most manifest during the treatment period and fell off somewhat during the post-treatment period, her behaviour is also perhaps partly ascribable—although far less than that of I and K—to suggestion. According to whether we omit or include J, the percentage improvement in the output of this group is only 1·6 or 2·9.

Output of Workers who were Benefited.

The forms of the work curves of hourly and daily output obtained for each of the 11 girls during the three periods of observation confirm the results

FIG. 3.



Hourly output of Worker H, measured in pounds.

derived from the weekly data of output. The work curves of hourly output after treatment indicate for A a reduction of fatigue at the end of the afternoon spell; for C a reduction of fatigue at the end of the morning spell; and for D a reduction of fatigue at the end of both spells. All these workers belong to the group whose output was increased by exposure to ultra-violet rays. The lessened fatigue at the close of each spell of work during and after treatment is illustrated in the case of D in Fig. 1. Instead of the fall that occurs in the continuous curve towards the end of the morning's and afternoon's work, the two dotted curves generally show a well-marked rise, indicating lessened fatigue and the ability to spurt as the work draws to a close.

Similar beneficial results are revealed by an examination of curves of the *daily* output of workers of the same group. After treatment A returns on Monday keen and interested, and is thus more than able to counteract the loss of adaptation and practice due to the week-end absence. After treatment C shows less fatigue during the latter half of the week. D now reaches a far larger output than before on Thursdays. B manifests a strong tendency to abolish her previous progressive daily diminution in output from the beginning towards the end of the week. This improvement is seen in Fig. 2.

The Output of Workers who were not Improved by Treatment.

A study of the curves of hourly output reveals in E after treatment a poorer start in the morning and afternoon, and greater fatigue towards the end of the

afternoon ; in F and G a poorer start in the morning, in G greater fatigue in the afternoon, and in H a slower improvement or an actual lessening of output during the early hours of the morning and afternoon. The curves of daily output indicate in F and G a more adverse "Monday effect" after treatment. Accompanying these deleterious signs, there are certain tendencies which otherwise might have resulted in increased output. E, F, and G all show in the hourly output curves after treatment a speedy and progressive recovery from their initial bad start in the mornings. H shows an increased ability to spurt during the last hour, especially of the morning spell (Fig. 3). The daily output curve of E, whose output showed no clear evidence of increase after treatment, indicates a less marked fatigue towards the end of the week after treatment.

Control Group.

J showed a worse initial start in the morning and very little evidence of any effect of the pretended treatment in the hourly and daily output curves. K's daily output towards the end of the week fell off considerably during "treatment," but became far better after it, although worse at the start. During "treatment" her hourly output curve showed a worse start, but reached a higher level in the afternoon ; after treatment her output was higher towards the end of the morning and afternoon spells. I showed the same lessening of fatigue towards the end of the spells, and a more uniform output from Monday to Thursday. These differences, however, are slight and are probably ascribable to suggestion and to accidental variations.

Conclusions.

The effects of ultra-violet rays on workers show *great indiaidual differences*. Four (Group I.) of the eight girls investigated showed a favourable effect, resulting in an average increase in their output by over 6 per cent. (in one worker 11·8 per cent.), and in consistent reports that they felt in considerably better health. Three of these four workers gave an extremely good cutaneous reaction to the ultra-violet rays. Of the remaining four (Group II.), one showed no change in output, and three an adverse effect. (One of these three workers was highly neurotic ; another was suffering from "colds." A third failed to give any cutaneous reaction to the rays.) Of the other three girls of Group II. who did not respond favourably to treatment, one gave a fair and the two others only average cutaneous reactions. With one exception the workers in Group II. failed to notice any improvement in general health.

It is important to bear in mind that the works in which this investigation was conducted are of a model character, situated at Greenford, Middlesex, and that the workers are of a superior type, living in the neighbourhood where they enjoy what almost amounts to country sunlight. More striking results might be expected if the experiments were repeated on a larger scale in a factory in some poor district of a crowded city. The employment of a control group is essential.

ROYSTON COTTAGE HOSPITAL.—The Prince of Wales recently opened a new children's ward in this Hertfordshire institution, which has always been free from debt. There is a hospital workers' league which contributes £1000 a year to the funds. Since it was opened in 1870 it has constantly been full and 25 per cent. of the patients have been children.

IMMUNISATION AGAINST DIPHTHERIA.—The Manchester Public Health Committee has reaffirmed its approval of a report by the medical officer of health, Dr. Veitch Clark, regarding immunisation against diphtheria. The medical officer recommended that a scheme for the free inoculation of children be put in operation by the Public Health Committee acting with the Education Committee at the school clinics, the welfare centres, and the civic buildings. Only children would be treated whose parents permitted.

Clinical and Laboratory Notes.

LEAD SHOT IN APPENDIX.

BY S. GILBERT SCOTT, M.R.C.S. ENG., D.M.R. & E. CAMB.,
RADIOLOGIST IN CHARGE OF THE X RAY DEPARTMENT, LONDON HOSPITAL.

MOST radiologists will have come across, at one time or another, unsuspected lead shot in the appendix, swallowed with game. A single pellet or even several need not necessarily give rise to inflammation, but in the following cases this was the sequela. For two reasons I consider them worthy of report : chronic appendicitis as a diagnosis was not suggested in any of them, and they were all seen within a period of four months.

CASE 1.—A middle-aged female had complained of pain in the right hip for some 16 years, which had been diagnosed by the numerous consultants, both in this country and abroad, as osteo-arthritis. Curiously enough, no radiographic examination had been carried out. Visits to various spas and treatment of all kinds led to no benefit and the pain persisted.

A general radiological survey was eventually suggested for a possible infective focus. This survey showed a normal hip-joint but eight small shadows in the right pelvis and a mass of calcareous glands over the sacrum. An opaque meal further demonstrated the shadows to be eight lead pellets in a fixed appendix. Operation confirmed the findings and the patient's symptoms disappeared. The patient confessed a weakness for grouse.

CASE 2.—By a curious coincidence this patient was sent to me for a general radiological examination the following week, on account of multiple arthritis and vague abdominal pains of some years' duration. Here again eight lead pellets were located in various parts of the appendix, which together with the cæcum, was firmly fixed. Operation confirmed the findings. A liking for partridge, a good partridge season, and faulty mastication were responsible for the condition.

CASE 3.—The symptoms in this case, including melæna, suggested a new growth of the rectum. An opaque enema was advised, but no radiographic evidence whatever was forthcoming of this condition. In the course of the examination, however, two lead shot were demonstrated in a low-lying appendix. An operation showed the appendix fixed to the pelvic colon, the two pellets being in the extreme tip.

CASE 4.—Frequency of micturition was here responsible for the diagnosis of some pathological condition of the bladder, or possibly calculus. The radiographic examination revealed no stone but a single lead pellet was detected in the appendix, which at operation was found fixed to the bladder.

CASE 5.—Vague abdominal symptoms were complained of in this case. The doctor, as "a shot in the dark," diagnosed the case as the menopause reflex, but was anxious to exclude any abdominal lesion. Here again a single lead pellet was seen in a low-lying appendix, which operation proved to be fixed to the right ovary.

CASE 6.—This case was referred to the Brook-street clinic for a general medical investigation. In addition to vague abdominal symptoms, there was a history of hæmatemesis. Radiographically no organic lesion of the stomach was detected, but two pellets were seen in the appendix, which in this case was quite free. An unsuccessful effort was made to manipulate the foreign bodies out of the appendix under the screen—I consider this manœuvre legitimate if there is no evidence of inflammation. In this case operation was not advised. A further radiographic examination of the appendix eight weeks later demonstrated that the pellets had been dislodged and passed.

Nature appears to have carefully camouflaged the condition of the appendix in these cases and the true state of affairs was only arrived at in the course of a general radiographic investigation. As would be expected, the condition is found more frequently in private patients. Now that a general medical overhaul, irrespective of symptoms, is possible, there is little doubt that more cases of this condition are detected than formerly. As previously mentioned, it is possible to have a pellet lodged in the appendix

ithout giving any radiological evidence of inflammaon such as fixation and, as illustrated in the last ıse, it may become dislodged and pass per vias ıturales.

Mastication must be very deficient nowadays. nyone having a gold denture or even metal teeth lings—and there are very few who have not—ecome conscious of the presence of any other metal ›ject in the mouth, as this creates a miniature ectric battery and a mild electric current. In any ıse, apart from this, the presence of a lead pellet in od should be readily appreciated by anyone who asticates this food to a reasonable extent. This ulty mastication is well illustrated by a girl present-g herself at hospital stating that she *thought* there as something stuck in her throat. A radiographic :amination demonstrated the presence of a full-sized)en safety-pin, which she had no recollection of ıving swallowed.

ARAPHENYLENE-DIAMINE LABYRINTHITIS.

By E. Watson-Williams, *M.C.*, M.Chir. Camb., F.R.C.S. Edin.,

HONORARY SURGEON, EAR, NOSE AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY.

Paraphenylene-diamine is the essential ingredient several popular hair dyes or "restorers." The ermatitis which in susceptible subjects may follow s use has already given rise to considerable litigation; is perhaps well, therefore, to recognise that other ssues may be damaged by this drug, which appears have a selective action on the labyrinth. Attention ıs been drawn to this in France by Dr. Paul ıurens:—

"Acute cases begin with vague giddiness, sometimes companied by nystagmus; tinnitus appears later and is ›essant. In the chronic form the same symptoms occur, d gradual deafness ensues. . . . This poison must not be ›gotten when treating obscure cases of toxic labyrinthine sease. The condition improves slowly when the dyeing stopped." [1]

The following is an illustrative case:—

Mrs. S. R., aged 33, was sent to me early this year. In r own words, "I have a noise in the left ear, and it makes › giddy and sick all the time." The ear had recently come "quite deaf." The first signs of trouble had peared in 1926, when attacks of tinnitus and "gastritis" gan to occur; but during the last three months there had ›en no remission, and tinnitus was severe and incessant. ue rotatory vertigo followed any movement, with a ıdency to fall to the left. During this period also she had d no appetite for breakfast, though other meals were less ›ected.[2]

On examination both drums were found to be retracted. ıere was slight nerve deafness in the right ear, very severe the left. Rinne's test was positive on both sides, and in ›eber's test the sound was referred to the right (good) ear. ıe left labyrinth appeared insensitive to caloric stimulation. ıere was no nystagmus. Inflation by means of a catheter owed that the Eustachian tube was normal, and produced change at all in the symptoms.

While discussing the possible causes of labyrinthine afness coming on rather rapidly in an apparently healthy ›man (Wassermann reaction negative), I noticed there was ash round the neck, more or less limited to the skin above ge of the collar of her blouse. This had been present and off for more than a year, but exactly how long the tient could not say as, although it itched rather at times, never got very bad and did not respond to anything she d done for it. On further inquiry I found she had been aring almost daily, and quite regularly during the winter, brown fur collar. This was kindly analysed for me by ›. A. L. Taylor, M.P.S., who was able to determine the esence in it of paraphenylene-diamine in demonstrable antity.

The fur, having been analysed, ceased to form part her wardrobe. She was advised to avoid all dyed r and (if tempted later) hair restorer, and a laxative was ordered. In ten weeks the hearing was normal, vertigo had ceased, appetite had returned, and tinnitus had almost entirely disappeared; the neck rash had vanished soon after leaving off the fur. There seems little doubt that the dye in the latter was the *fons et origo mali*. If so, it appears that dye in fur can, to a susceptible subject, be as dangerous as when applied to the scalp; doubtless, this was a relatively mild case of poisoning.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF COMPARATIVE MEDICINE.

At a meeting of this Section held on May 23rd, with Sir D'Arcy Power, the President, in the chair, a paper on

APLASTIC ANÆMIA

was read by Dr. J. P. McGowan. It was largely an account of researches at the Rowett Research Institute, Aberdeen, on benign aplastic anæmia in pigs. He said that just as in the hyperplastic conditions there were secondary or benign anæmias on the one hand, and primary malignant anæmias—e.g., pernicious anæmia—on the other, so in the aplastic variety there were benign or secondary aplastic anæmias, such as that occurring in the pig, and malignant anæmias, such as those following benzol poisoning. In pigs aplastic anæmia seemed to arise essentially from a deficiency of iron in their milk-supply, relative to its protein content. The onset of the disease was at birth, and it reached its climax at about the third week thereafter. By this time the animals affected had become abnormally fat, "stocky," and pale; they were subject to diarrhœa, and had a heaving or pumping form of respiration. At this stage, too, they showed profound anæmia, with a colour-index of less than 1. Sudden death was common, and the chief post-mortem findings were great cardiac dilatation, and effusion of fluid into all the serous cavities of the body. Fatty change was seen extensively in the lobules of the liver, and the lungs were œdematous. The blood changes were leucocytosis, of fairly marked degree, with a good deal of anisocytosis and slight poikilocytosis. Films also showed numerous macroblasts and normoblasts. Megaloblasts were absent, but there was a marked polychromasia. Only in the last few days of the life of the pig was the skin noticeably jaundiced. In its first phase the disease seemed to be due to lack of iron, while in its second damage to the liver of a mechanical type appeared to be the determining factor. The persisting nature of the cause possibly accounted for the aplasia being more marked than in other secondary anæmias.

In discussing the changes present in this form of aplastic anæmia Dr. McGowan brought forward evidence to show that erythropoiesis was essentially, even in the mammal, an intravenous phenomenon and that the megacaryocyte, by amitotic fragmentation, played a predominant part in the production of erythroblasts from which the erythrocytes were formed. Jaundice of an obstructive type occurred as a terminal phenomenon in this condition. Nevertheless, the serum, when tested by the ordinary van den Bergh technique and reagents, gave a delayed direct and indirect reaction only. It was found, however, that dilution of the serum in buffer solution, instead of distilled water, or the use of a less dissociable acid than HCl, such as acetic acid, in the preparation of van den Bergh's No. 1 solution, allowed of an immediate direct reaction being obtained. The alcohol used in the ordinary van den Bergh technique for the indirect reaction possibly acted in the same way by lessening the dissociation of the HCl in the reagent and so affording a favourable H-ion concentration for the development of the colour change. It

seemed therefore that there was a case for reconsidering the interpretation of the clinical significance of the van den Bergh reaction.

Comparing aplastic anæmia in the pig with pernicious anæmia in the human being, Dr. McGowan pointed out that in both conditions there was general adiposity, and also a fatty change in the centre of the liver lobules. From a consideration of the facts relative to aplastic anæmia Dr. McGowan had some time ago arrived at the conclusion that there was a complementary action existing between the liver and bone-marrow in relation to blood formation, amounting almost to a single-organ activity. Subsequently Minot and Murphy had published their results on the beneficial results of liver feeding in pernicious anæmia. Feeding of liver to a pig affected with aplastic anæmia had been undertaken, with resultant very marked improvement in the blood condition. From a consideration of the liver and bone-marrow changes and the result of liver feeding in this benign aplastic anæmia as compared with those in pernicious anæmia Dr. McGowan deduced that an organic lesion of the bone-marrow was an essential condition of the pathogenesis of the primary or malignant blood conditions. Peabody, in America, suggested that in human pernicious anæmia, the giving of liver acted by causing maturation or ripening of the precursors of the red blood cells. Dr. McGowan thought that while this might be part of its action where there was deficiency of iron, it could not be its whole action in pernicious anæmia, in which the betterment consisted in a change from the embryonic to the adult blood forms. Such transformation from primitive to definitive blood type in the embryo was associated with the onset of hepatic erythrogenesis. Therefore it seemed that there was some deep-seated biological relationship between the tissues, quite apart from a ripening.

Dr. H. P. BAYON pointed out that the pig disease under discussion began with a hyperplasia of the marrow, the aplastic anæmia being the terminal symptom rather than the primary or main process. What ought to be stressed in this disease was the state of the bone-marrow. When a state of exhaustion of bone-marrow was reached aplastic anæmia supervened.

Discussion.

Dr. ALFRED PINEY said that aplastic anæmia meant an anæmia due to aplasia of bone-marrow. But he gathered that these pigs developed anæmia, and later had an aplastic bone-marrow. Normally, the name aplastic anæmia was applied to a condition in which active regeneration by the marrow as a whole was absent. These pigs, however, had leucocytosis, which was a sign of activity in the marrow. There were also other indications of activity. He therefore preferred to regard the condition as a severe secondary anæmia, in which the blood-forming organs might ultimately become aplastic. The marrow was dark-red in colour, as it was in pernicious anæmia, and was also very cellular. Photographs shown by Dr. McGowan clearly showed the existence of an advancing edge of red marrow. If it was truly an advancing condition, then "aplastic" seemed the wrong term to use. To call an anæmia which started with such a marrow "aplastic" was to invite confusion; it only became aplastic terminally. He would be interested to learn what was the effect of giving these pigs the protein-free liver extracts which were now successfully used in pernicious anæmia.

Dr. A. KNYVETT GORDON also considered that the condition was due to a proliferative change which ultimately became aplastic. Pernicious anæmia in man was a very different disease clinically from aplastic anæmia. The latter could be produced by the injudicious use of X rays in the treatment of leukæmia, and sometimes proved fatal. An aplastic condition of the bone-marrow was likewise met with in the terminal stage of sepsis. Aplastic anæmia was curable, and it must be recognised as a very different condition from pernicious anæmia.

Dr. PARKES WEBER said he considered that the sections of liver demonstrated by Dr. McGowan showed central acinous atrophy. He suggested that perhaps Dr. McGowan would work out the changes in the liver of these pigs and compare them with the various kinds of central acinous atrophy of the liver in human beings.

SUBSECTION OF PROCTOLOGY (SECTION OF SURGERY).

AT the May meeting of this Subsection, with Sir CHARLES GORDON-WATSON, the President, in the chair, Sir WILLIAM WHEELER opened a discussion on the

EARLY DIAGNOSIS OF CARCINOMA OF THE RECTUM AND COLON

by calling attention to the late diagnosis usually made, the high final mortality, and the relative frequency of cancer of the distal parts of the gastro-intestinal tract. He maintained that in just these parts an early diagnosis ought to be made for from the diagnostic point of view cancers of the distal colon were external cancers. Yet most surgeons had the same lamentable experience of late recognition. In a series of 47 consecutive cases in his own experience 24 had had carcinoma of the colon and 23 of the rectum. Of the former, half had been inoperable and of the latter only 7 had been operable. The results of early operation were very good, and the operative mortality had become negligible. The weak link in the diagnostic chain seemed to be the lack of thorough examination in suspected cases. On an average, ten and a half months had elapsed between the first consultation with a doctor and the final diagnosis. Allowances must be made for the busy practitioner when, as often happened, the predominating symptoms in early cancer of the lower bowel pointed to mischief high in the abdomen. Normally certain foods produced peristalsis; in the presence of a neoplasm accompanied by spasm of the pylorus there might be pain after food, some nausea and a little vomiting, so that a diagnosis of cholecystitis or even of displacement of the uterus might quite reasonably be made. Many cases had been X rayed for dyspepsia when the cause of the trouble lay within easy reach of the rectal finger. The number of cases mistaken for piles was notorious. Rectal examination should always be done bimanually and as thoroughly as the vaginal examination of the gynæcologist. Insufficient attention had been drawn to the simplicity of a sigmoidoscopic examination and to the means of overcoming the small difficulties encountered. The sigmoidoscope had been well described as "an elongated finger fitted with a human eye." If the sigmoidoscope were more used these growths might often be noticed in a precancerous stage. No examination was complete without a opaque meal and enema, but the general practitioner should be warned that radiologists were not miracle-mongers, nor their pronouncements akin to the gospels. It was a great mistake to take a radiologic report as proof positive of the presence or absence of a new growth; 90 per cent. of palpable growths were felt per rectum. Of growths in the sigmoid 24 per cent. were palpable, but the examiner was much more likely to feel the accumulation of fæces above the growth. Size bore no relationship to malignancy. Between a cancer and a tuberculous there was no possible means of distinguishing, and actinomycosis was only to be diagnosed when a sinus had actually discharged sulphur granules. Growths of the splenic and hepatic flexures were difficult to feel, but might be detected more easily if the patient stood up and bent forward while the surgeon examined him from behind. There was no doubt that two independent growths might be found in the same individual at the same time.

A positive benzidine test was good enough for him, said Sir William, as an indication of occult blood. A patient with a distal cancer of the intestine might remain in good health until a very late stage, if absorption was not interfered with, but growths of the right side of the colon produced marked anæmia and toxæmia even without occult blood in the stools. There was some evidence that this condition was due

the activity of the *Bacillus welchii*, and that the titoxin of this organism was of some value. næmia in a case of carcinoma of the colon was never contra-indication to operation, in contrast to tients with gastric growths in whom anæmia always eant wide local infiltration or metastasis. The ood-sugar tolerance curve was said to differ in cases gastro-intestinal cancer from that in cases of ncer elsewhere. The Wassermann test must not be glected, although he himself had never seen a icture of the rectum or colon attributable to philis. Exploration should be the last thing of all an investigation. If there were occult blood in e stools, and the symptoms were suspicious and e X ray negative, the case should be watched and vestigations repeated. If, however, there was a lpable tumour or the X ray was also suspicious, e case should be explored.

The crux of the whole problem was, however, at symptoms should make a doctor suspicious ough to insist on X ray, sigmoidoscopic, and other vestigations. Change in bowel habit was mentioned every authority. A man who had been able to t and drink what he liked insidiously became a speptic when a cancer of the stomach was developing. the same way the cast-iron regularity of the wel habit disappeared in cancer of the intestine. careful history must be taken. Age did not help ch; cancer of the rectum might appear before e age of 20, but cancer of the colon was not apt to pear early. Visible or palpable peristalsis proved at there was obstruction somewhere. The rectum s very intolerant of foreign bodies, and teasing nesmus with mucus discharge was a prominent ture of later date. There were no pathognomonic ns, only a conglomeration of factors. For the tient who would not seek medical advice and who ctored himself for his trivial symptoms nothing atever could be done.

The Help of the Pathologist.

Dr. CUTHBERT DUKES said that only in the croscopical examination of a fragment of the nour could the pathologist be of any real assistance. ere were at present no reliable means of recognising se changes in the blood which must accompany cer from the first. Alterations in the urine peared too late, and there were many other possible rces of blood in the stools. It was worth while aring in mind that innocent adenomata were quently precursors of carcinoma, and that early wel cancer was often accompanied by a cluster of sile adenomata and patches of epithelial prolifera- n of the mucous membrane. The piece removed for amination should be from the very edge of the nour, showing normal side by side with neoplastic sue. Reliance could not be placed on the rphology of individual cells; the general arrange- nt of the epithelium must be considered, together h the only infallible sign—the intrusion of a ical epithelium into regions where it was not rmally found. The piece should not be squeezed or shed or cut during removal, but should be taken by dissection or by a punch and dropped into ative as soon as possible. If the surgeon insisted an initial report from a frozen section, he must prepared for that report to be non-committal. He st also remember that the report referred only to at part of the tumour sent up for examination, and at a negative report did not necessarily mean that e whole tumour was benign. Dr. Dukes then showed eries of beautiful preparations in illustration of points that the only certain sign of cancer of e bowel was invasion of the subjacent tissues, that e superficial diameter of an ulcer or tumour was solutely no indication of the depth of its penetration, d that satisfactory specimens for examination could removed by special instruments.

The Assistance of Radiology.

Dr. GRAHAM HODGSON said that an efficient liogram could confirm suspicions, localise the owth, and define its extent. The most important signs were: filling defect, localised absence of peristalsis, and distension proximal to the stricture. To detect the more important smaller filling defects the oblique view was essential. An antero-posterior view might give the appearance of a growth at the upper end of the rectum when a complete examination would show that the trouble really lay in the sigmoid or rectosigmoidal junction, with ballooning of the sigmoid and rectum. It was impossible to exclude a filling defect until every inch had been examined in direct and oblique views, as Dr. Hodgson illustrated by slides. Another useful method was the dual exposure. The bowel distended with warm fluid showed rapid peristalsis, and if two photographs were taken at intervals of a few seconds without an intervening respiration a peristaltic wave would be recorded. Over the site of a growth the double shadow would be absent, owing to the localised absence of peristalsis. Apparent filling defects might be due to inadequate emptying of the bowel before the enema or to localised spasm. The latter could be overcome by lowering the enema can to a foot or so for five or ten minutes, meanwhile massaging the spasm, which would then gradually relax. A true filling defect might be due to adhesions. A hard inspissated mass of barium proximal to a colotomy opening was a surgical complication which might result if operation were performed within a day or two of the barium examination.

Dr. A. F. HURST said that improvement in medical education was the most important measure of all. It was appalling how late these cases reached physician or surgeon. In the vast majority the condition could be diagnosed six months earlier than it was. Warning signs were definite abdominal symptoms after a period of health, discomfort, and some change in the regularity of the bowel. In only 5 out of 25 cases in his experience had naked eye examination of the stools showed any abnormality, but occult blood was one of the most constant signs, although it might also be present in tuberculosis, chronic intussusception, and localised adhesions. It was very important to realise that in some rare cases of advanced growth the barium enema might show absolutely nothing. The shape of the filling defect helped to distinguish a growth from other conditions. Until the sigmoidoscope was recognised as being an instrument for the physician and the general practitioner, a large number of cases would be missed. In the earliest cases of all the diagnosis must be made on the history and the presence of occult blood in the stools. A patient might complain of a feeling of discomfort which was relieved when he felt gas pass through some local area with a gurgle. Now that many patients recovered from ulcerative colitis, stricture following this condition was less rare and might simulate a growth.

Mr. J. P. LOCKHART-MUMMERY said that the whole problem now came down to early diagnosis; operative results were admirable. X rays should never be taken as negative evidence, but were very useful as confirmatory. In his experience most patients would submit to an exploratory laparotomy, and he advised it in doubtful cases. The problem of getting cases early enough lay with the patient and the practitioner. The condition caused so few symptoms that patients often did not consult a doctor, and were most unwilling to submit to the unpleasant examination necessary to confirm the diagnosis. The general practitioner was realising the importance of the matter, but education of the public was very necessary.

Mr. W. B. GABRIEL suggested that annual medical examination would catch many cases early.

Mr. LIONEL NORBURY agreed with the value of routine examinations, and narrated two cases where the sigmoidoscope had revealed early growths quite unexpectedly in patients under 40 with a history of recent origin of piles. The fault did not lie with the practitioner but with the panel system which made rectal examinations quite impracticable.

Dr. CLAUDE GOULDESBROUGH confirmed Dr. Hodgson's remarks. He had overcome the difficulty

of overlapping shadows in many cases by raising the foot of the table, and having the enema pot on a level with the patient's body so that the barium trickled in very slowly. By turning the patient a little on one side the outline could be made clear. The patient's feet could then be lowered and the rectum slowly emptied, so that the sigmoidal outline appeared clear of the rectal shadow. A good idea of a small stricture could be obtained by syphoning back some of the fluid and then running it in again. Belladonna might be useful for overcoming spasm. Fixation of the colon was very important in showing that something was seriously wrong.

Mr. E. T. C. MILLIGAN said that adenoma and carcinoma might appear identical through the sigmoidoscope, but induration might be palpable. Palpation was therefore important, even if it involved opening the abdomen; otherwise a rectum might be removed for an innocent growth. No aperient or wash-out should be given before sigmoidoscopy, because this changed the appearances of the bowel contents, which were important. If normal fæces were seen through the sigmoidoscope it was some evidence against the presence of a growth higher up, and vice versa.

Reviews and Notices of Books.

TAYLOR'S MEDICAL JURISPRUDENCE.

Principles and Practice of Medical Jurisprudence. Eighth edition. Edited by SIDNEY SMITH, M.D., D.P.H., and W. G. H. COOK, M.D. London: J. and A. Churchill. 1928. Two vols. Pp. 900 and 964. £3 3*s*.

Taylor's "Medical Jurisprudence," the great classic of forensic medicine, has for 50 years been indispensable to two professions. At the present time a new edition is of peculiar value, since medico-legal questions of importance are under discussion and the relations of doctor and lawyer are in a critical stage of transition. The eighth edition maintains all the traditions of the book, while it keeps abreast of modern research and controversy. The last decade has seen legislative activity in many directions which concern medical men; to mention only a few statutes, the Coroners' Act, the Births and Deaths Registration Act, the Legitimacy Act, and the Midwives' Act, were the work of a single year. The new edition refers to many notable cases of recent times, such as Beard *v.* Director of Public Prosecutions, Rex *v.* Bateman, Rex *v.* Armstrong, and Rex *v.* Kynaston. Advances in medical and ancillary sciences have caused many changes in medico-legal technique, and have necessitated revision of the chapters on identification, injuries to the head, and injuries from fire-arms, among others. There is a good deal of new material in the section on fire-arms, describing the characteristics and identification of bullets and weapons. The chapter on bloodstains has been considerably altered; the guaiacum test is described, but is regarded as obsolete since the introduction of simpler colour tests with benzidine, phenolphthalein, and other bases. The action of these depends on the fact that there is a substance, probably a peroxidase, in the colouring matter of the blood which, in the presence of hydrogen peroxide, transforms them rapidly through oxidation from colourless bases to coloured salts. The benzidine test, which is perhaps the most satisfactory, consists of the application to the suspected material of a 10 per cent. solution of paradiamo-diphenyl in glacial acetic acid, to which has been added twice its volume of hydrogen peroxide. If the stain is due to blood, a deep blue colour immediately radiates out on to the filter paper on which the test is performed. Other substances (sputum, pus, and certain bacteria.) give a positive reaction, but never such a rapid one. This test, like all similar ones, is chiefly of negative value, and further examination is necessary to prove the presence of hæmoglobin. In spite of the advances which have recently been made in the study of blood groups, the precipitin test is still made the principal means for identifying human blood, and the possibilities of the agglutination test are regarded with caution. The toxicological sections have been largely rewritten, and the analyses made on Mr. Armstrong, Mrs. Greenwood, and the victim of the Seddons are given in full.

The department in which most alteration has been necessary is that dealing with the legal position of the insane. Several judicial pronouncements and the results of certain trials, notable that of Ronald True, have thrown the question of criminal responsibility in mentally disordered persons into prominence and in each profession a body of opinion is advocating revision of the rules in McNaghten's case. The findings of the Lord Chancellor's Commission of 1922 are given in full, with impartial comment on the different views expressed by various medical and legal authorities, especially on the question of impulse. The use of the word "insanity" where the earlier edition gave "lunacy" marks a step forward. The wood-cuts of the early editions were nearly all omitted from the fifth to make room for more letter-press, and because Hofmann's "Atlas of Legal Medicine" illustrated the book better than its own pictures could do. Now, illustrations have appeared again, chiefly in the sections on identity and wounds, and they are certainly welcome. The format of the work is much improved by the innovation of neat, dark-blue covers and a clearer fount for the cross and side headings and for the index words in the table of contents.

TUBERCULOSIS.

Modern Aspects of the Diagnosis, Classification, and Treatment of Tuberculosis. By J. ARTHUR MYERS, Associate Professor of Preventive Medicine, Medical and Graduate Schools, University of Minnesota. London: Baillière, Tindall and Cox. 1927. Pp. xii.+275. 25*s*.

Dr. Myers remarks in his preface that "nothing is so mischievous in the campaign against tuberculosis as the notion that only a small group of physicians are competent" to diagnose and treat the disease. He has therefore endeavoured to gather together facts concerning the tubercle bacillus, and the diagnosis, treatment, prognosis, and prevention of tuberculosis, which may be quickly grasped and applied alike by the student and the practitioner of medicine. A study of tuberculosis intended for students should be concise, well illustrated, and so arranged that a reader with little experience to guide him in his selection can readily distinguish between matters of vital and those of only minor import. In these respects, and particularly in the last, Dr. Myers's book is not wholly satisfactory, but the practitioner will read with interest and profit a book which traces the history of tuberculosis from the days of Hippocrates to those of Trudeau, and provides much information of value concerning the pathology, symptomatology, and treatment of the disease. The best chapters are those devoted to the general management of the tuberculous patient and the principles upon which treatment, whether carried out at home or in the sanatorium, should be based. In this country the provision of treatment for the tuberculous has limited the responsibility of the private practitioner who is apt to feel that his duty ends when a patient has been "duly notified" as tuberculous. The patient whose name is on the sanatorium waiting-list is often advised to "get as much fresh air as possible," and may spend his time in walks which entail considerable exertion at a time when every hour of rest would increase his frail chance of recovery. The words of Dr. Hawes, of Boston, which Dr. Myers quotes, are the statement of a truth that is sometimes forgotten: "the patient's stay at the sanatorium is but an incident in a course of treatment, the most important parts of which are before the patient enters and particularly after the patient has left the sanatorium." Dr. David Stewart

as crystallised the modern theory in the statement hat "the medicine called exercise must be prescribed n exact doses and marked with a poison label." Most f the instruction given by Dr. Myers is sound, but n occasion he ignores the general needs of the atient. Thus in his zeal for thermometry he forgets ne desirability of sound sleep and advises that the atient's temperature should be taken "every two ours throughout the 24 hours" for a period of a w days.

Not all the illustrations in the section on Radiology re convincing. The picture designed to demonstrate ne appearance in a radiogram of a tuberculous cavity ils to show one, and a similar criticism applies to a gure referred to as illustrating the cone-shaped nadows described by Dunham. A printer's error as apparently transposed the descriptions of the two ictures of pulmonary exudate in process of absorption. he student is advised that he must "try to differenate between true intrapulmonary cavities and leural shadows which may be localised pneumonaces or localised pleurisies," but the author omits explain how this differentiation is to be made. wo chapters are devoted to brief descriptions of odern surgical methods, including artificial pneumonorax, phrenicotomy, and thoracoplasty, and a apter on heliotherapy gives a short account of this ethod of treatment. The statement that "splendid" sults are obtained by the use of X rays in the eatment of lupus should not pass unchallenged. alignant disease has not seldom resulted from the plication of the rays to this condition.

HE BASIS OF SENSATION.

By E. D. ADRIAN, M.D., F.R.S., Fellow of Trinity College, Cambridge. London: Christophers. 1928. Pp. 122. 7*s.* 6*d.*

THE work described in this interesting little volume purely physiological, although an application of ne results obtained to problems of mind is by their ery nature invited. Here Dr. Adrian hesitates to ead, content for the moment to consolidate the ains acquired by physiological technique.

It has long been known that for practical purposes ne impulses set up in motor nerves (isolated for xperimentation) by electric stimuli represent the ssential activity of such nerve-fibres in the living ody. These impulses are momentary disturbances assing along the fibre to the accompaniment of hanges in electric potential; owing to the interposition of a phase or period of a refractory character ne impulses are discrete, even if extremely rapid, nd a continuous transmission of the state of excitation impossible. The question for consideration set imself by Dr. Adrian was whether sensory fibres ould be found to behave differently—work done ong this line has hitherto been comparatively anty and to some extent inconclusive. By means an ingenious use of the capillary electrometer and new amplifier (based on technical improvement those in use for wireless purposes) he has been ble to study the action currents excited in sensory erves; equally ingenious is his method for emonstrating these in a single sensory fibre. He olated a strip of the sterno-cutaneous muscle of the og, eventually obtaining a preparation in which nly one muscle-sense end-organ (muscle spindle) as present. From this delicate little piece of tissue e was able to prove that on stimulation the muscle eceptor (sensory end-organ) discharges a regular iscrete series of impulses when stimulated, and that ich differences as exist between the activity of ensory end-organ and of sensory fibre, registered ectrically, are quantitative and not qualitative. he impulses in sensory fibres are of precisely the me type as those already familiar in motor fibres—conclusion which is clearly of high significance. he author's next research was to compare the sensory ischarges from various types of receptor, and for is he tested pressure end-organs in one of the toeads of the cat, touch organs in the same, movement of a hair in the cat's ear, pain organs in its foot, and, further, visual receptors in the eye of the eel. From the standpoint of electrical result the fundamentally important conclusion is reached, that there is no specific activity in sensory nerves corresponding to each type of sense organ; the nervous impulse is common to all, and to the motor nerve-fibre.

Since then, sensations differ while sense impulses do not, differentiation is a central and not a peripheral phenomenon. The significance of the fact that identical discharges are found in the optic nerve can be expressed in a word; connecting fibres within the central nervous system communicate by impulse-discharges of the same type as those in the peripheral fibres. As Dr. Adrian quietly remarks, "there is nothing very startling in this conclusion, but it is satisfactory to have reached it." As for the relation of sensory nerve impulse to central sensation, of physical current to change in consciousness, here at once we find ourselves in deep water again. Dr. Adrian shows, with precision, that the intensity of sensation at any moment is directly proportional to the frequency of impulses in sensory nerve-fibre, but the underlying relationship remains undetermined. With scientific modesty and suspension of judgment, he declares that the gap between stimulus and sensation is not yet bridged—it is only a little narrower than it was before.

VAGOTONIES, SYMPATHICOTONIES, NEUROTONIES.

Second edition, entirely recast. By A. C. GUILLAUME. Paris: Masson et Cie. 1928. Pp. 562. Fr.40.

THE first edition of this work was reviewed in our columns appreciatively some considerable time ago; this second edition is more than twice as long (562 pages instead of 250). Doubtless such an extension represents a real accretion to knowledge of the sympathetic system, in health and disease, but it is curious how much of this is still characterised by assumption and speculation, by probabilities and not by certainties. Dr. Guillaume recounts at great length the clinical aspects of vago-sympathetic disequilibrium, and inserts new chapters dealing with its interrelation with blood conditions, and on the psychical phenomena accompanying this disorder of balance, inclusive of the neuroses. The book is replete with information of the most diverse kinds, and its bibliographical references leave nothing to be desired. Closely printed, and at the same time readable, it reveals its author's erudition and clinical flair on almost every page. Suggestive as are many of his conclusions, we still are conscious of the impression that pathological confirmation of these has been in various instances outrun, and that the fundamental basis of advance in exact knowledge requires much more attention than has hitherto been assigned it.

TECHNIQUE OF SWEDISH MEDICAL GYMNASTICS.

By Dr. J. ARVEDSON, Director of Arvedson's Gymnastic Institute, Stockholm. Translated by MINA L. DOBBIE, M.D., B.Ch., Medical Officer, Chelsea College of Physical Education. London: J. and A. Churchill. 1927. Pp. 259. 12*s.* 6*d.*

THOSE interested in physical treatment will welcome this little book. It is essentially a reproduction of the chapter by Dr. Arvedson, which appeared in "Kleen's Massage and Medical Gymnastics," first published in this country ten years ago; such additions as have been made are all to the good, and the volume provides an authoritative account of Swedish remedial gymnastics. There are certain criticisms which will occur at once to the English reader. Sherrington's work on the action of muscles is not, we think, given adequate prominence. Space devoted to the performance of various exercises in which the attention of two gymnasts is required might have been spared for more theoretical instructions; for, in this country, at least, exercises of this type are a luxury not easily attained, and many

of those given are of doubtful utility. Furthermore, the student in training will have to supplement this book by others, various important exercises being omitted; for example, Klapp's crawling exercises merely receive mention as a desirable form of exercise in the treatment of scoliosis, no details being given. But the profuse illustrations are clear and well produced, and the index is well compiled. The addition of a list of recognised abbreviations would add to the value of future editions. Dr. Dobbie has provided an excellent translation, for which students will be grateful.

THE HISTOLOGY OF SKIN DISEASES.

Histobiologie der Plant. By JOSEPH KYRLE, Prof. Dermat., Univ. Vienna. Vienna and Berlin: Julius Springer. 1927. With 176 illustrations, mostly coloured, in the text. Pp. 287. Unbound, R.M.42.

THE author of this admirable work, the first volume of which we reviewed two years ago, died after a long illness, in May, 1926. He was regarded as one of the most promising of the younger school of dermatologists in Vienna, and was the author of many original monographs. It is generally deplored that he did not live to complete the third volume of the series of lectures which would have dealt with the histology of cutaneous tumours. This collection was edited by his colleague, Dr. von Planner, and has earned the commendation, in a short preface, of the severely critical chief of the clinic, Prof. E. Finger. Each volume contains 35 lectures, and in this group we are introduced to the inflammatory groups of dermatoses, acute and chronic, which include syphilis, tuberculosis in its many forms, Delhi sore, leprosy, lymphogranuloma, and mycosis fungoides. The colloquial style of presentation, reinforced by the superb coloured drawings of actual microscopic slides. will be appreciated by dermatologists and pathologists the world over. Theoretical explanations of the complex processes that underlie the morbid histology of individual diseases are not lacking. Discussions of such subjects as the effect of a virus on nerve-endings, or on the capillary reaction and permeability, show how fundamental and far reaching are the biochemical problems yet to be solved in dermatology. Of particular interest and importance are the paragraphs on the herpetic groups, and on the so-called "dermotrophic" viruses, and on the latest theories of sensitisation. which last section forms a prelude to the introduction of a dissertation on eczema. The differences between simple and chronic inflammatory reactions are well brought out in the lectures on tuberculous and "meta-tuberculous" affections, in which latter group are included lupus erythematosus and granuloma annulare. In the succeeding chapter, the meaning of such phenomena as "allergy" and "anergy" are discussed, and also the function of the skin as an immunising organ. The general arrangement of these lectures follow the classical lines of the Hebra school; there is a good index, and the reference to the literature proves most painstaking reading and memorisation.

Under the title "Die Blutgefässe der Menschlichen Haut und Ihr verhalten Gegen Reize" a German translation has been published of Sir Thomas Lewis's book on "The Blood Vessels of the Human Skin and Their Responses," reviewed in THE LANCET of May 19th. The authorised translator is Dr. Erich Schilf, extraordinary professor in the Physiological Institute of the University of Berlin. The publishers are S. Karger, Berlin, and the price is 24 marks for a bound copy.

Crawford W. Long and the Discovery of Ether Anœsthesia.—This book, by Frances Long Taylor, which was the subject of annotation in THE LANCET of March 17th (p. 566), is now issued in this country by Humphrey Milford, Oxford University Press, at the price of 18*s*.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE.—The first article in the April issue, although short, is important. In it E. L. Collis and J. C. Gilchrist deal with the effects of dust upon coal-trimmers. They show that these workers suffer rather less than most men from tuberculosis, but distinctly more from bronchitis and pneumonia. Radiographs exhibit signs similar to those widely regarded as characteristic of silicotic fibrosis. The authors point out that the "snow-storm" variety of shadows in radiographs can only be regarded as diagnostic of silicosis when found among workers exposed to a silica risk; they may and do occur among workers exposed to other dusts which do not predispose to tuberculosis. The point is important, especially as compensation for silicosis may shortly be granted to coal-miners exposed to a silica hazard in driving hard headings. The other two articles which make up the number are reports from the Engineering Committee of the American Conference on Electric Shock. The first deals with statistics of fatalities due to electric shock in the United States and Canada, in England, and in Switzerland. The figures show a much lower incidence in England and Wales than in the other two countries, while the rate for the United States is above that for Switzerland. Electricity is more used in the other countries than in England, but not to an extent sufficient to account for the much higher rates. The second article analyses 265 electrical accident cases dealt with at electric supply plants in America with regard to the Schäfer method of resuscitation. This subject is referred to on p. 1130 of our present issue.

May, 1928: Poisoning by arseniuretted hydrogen arising when pickling metal sheets, and due to accidental presence of arsenic in the acid used or in the metal, is well discussed by C. W. Muehlberger, A. S. Loevenhart, and T. S. O'Malley. The paper is chiefly of value on account of a complete bibliography of cases of arsine poisoning. The second contribution is by A. R. Riddell and H. E. Rothwell, who deal with certain aspects of silicosis as seen in Ontario. Of especial interest is a table giving the silica content of 19 different lungs; it varied from 39·8 per cent. of silica in the ash of dried lung from a driller of silica stone to 0·6 per cent. in the case of an ordinary city dweller. Excellent plates illustrate radiographs of the chest, and the macro- and micro-scopical appearance in three of these cases of definite silicosis.

Reports and Analytical Records.

GOLD LEAF BRANDY (No. 1).

(J. DENIS HENRY MOUNIÉ AND CO., COGNAC.)

ON analysis this brandy, which is stated to be 20 years old, gave the following results:—

Alcohol, by volume	46·12 per cent.
Proof spirit	80·75 ,,
Alcohol under proof	19·25 ,,
Extractives containing sugar	0·93 ,,

Secondary products expressed as parts per 100,000 of absolute alcohol:—

Acidity (acetic acid)	26
Aldehydes	22
Furfural	2·5
Esters as ethyl acetate	108·5
Higher alcohols	200·0

These results support the claim that the brandy is a pure product of the grape. It has not been blended with neutral spirit. The aroma is good and the palate agreeable. The brandy is a suitable and economical one for medicinal purposes, and when recommending its use, it should be borne in mind that it is stronger than many other brands, the customary strength in this country being 40 per cent. of alcohol which is equivalent to 70 per cent. of proof spirit.

THE LANCET.

LONDON: SATURDAY, JUNE 2, 1928.

THE TREATMENT OF CRIME.

ON May 21st the House of Commons went into Committee of Supply on a vote of £473,969 for the expenses of prisons in England and Wales. The date is significant, for on May 21st, 1780, one was born who was to give her life to making our prisons what they are in process of becoming—centres for the reformation of the criminal, hospitals for the cure of crime. When ELIZABETH FRY paid her first visit to the female ward at Newgate in 1813 she found it "a den of wild beasts; women, cursing, fighting, dancing, screaming over their games of cards; all idle; all contaminated for ever by the foul smell of the dungeon." Prisons in those days were "verminous dens where staring wretches lay in irons on filthy pallets of straw," and though in our own time these institutions have their defects, the revolution in their management already seems astounding. No less an observer than Prebendary CARLISLE, of the Church Army, writing to the *Times* a year ago, maintains that "with their training schemes, their concerts, their sermons, their games, the prisons have in 30 years reduced their daily populations from over 30,000 to less than 11,000, and the prisons from 66 to 33." The very word "cell" has been abolished, and solitary confinement has disappeared in the most advanced of our institutions; "warders" and "prisoners" are now "officers" and "men"; pictures, flowers, and curtains adorn the forbidding interiors; and in each the most treasured of all possessions, a library, with scores of books and papers, is installed. In the course of the debate, Sir VERNON HENDERSON, Under Secretary to the Home Office, was able to reply, in answer to questions, that every effort was made to improve the accommodation at prisons, and their recreation and workshop facilities; that every step was taken to see that where clothing was handed over from one man to another it was thoroughly and properly disinfected, and that in no case was it in a condition where it could convey any disease to anybody; that there was no reasonable ground for complaint on the score of prison diet which had been very considerably improved, particularly in variety; and that the problem of alcoholism was largely non-existent so far as the prison population was concerned.

To those familiar with prison administration these remarks may seem a commonplace; to others they will be reassuring. But certain other statements in the Under Secretary's reply require serious consideration. Sir VERNON said that arrangements are now being made by which persons regarded by the prison medical officer as possibly mental defectives are transferred to a prison especially adapted for their needs, or where special treatment is given, as at the prison at Birmingham. This seems to suggest that certain prisons are being set apart for the training of mental defectives—a suggestion which we must comment upon. The tendency to-day is to group prisoners together in large establishments; thus Holloway is the women's prison for no less than 17 counties. Similarly, we understand that prisoners exhibiting mental symptoms are sent for observation to certain prisons where special facilities exist. Parkhurst is one of these, Birmingham another. Here ascertained mental defectives should be certified, and transferred to the care of the Board of Control in Lunacy. Under the principal Mental Deficiency Act (1913) many of these mental defectives could not be certified; the Act of 1927, however, removed those difficulties, and it became the duty of the Prison Commissioners to see that they were no longer kept in prison. There are, however, certain prisoners who can neither be certified as insane nor dealt with as statutory mental defectives, yet are incapable of being treated as ordinary prisoners because they are (so to say) non compotes mentis. Of such persons, 77, according to the latest returns, are recorded as being in prison, where they receive special treatment in a separate institution. It is these prisoners to whom Sir VERNON HENDERSON referred as "mental defectives." Mental defectives undoubtedly they are, but they ought not to be thus confused with those to whom alone this specific statutory term applies—namely, those who are certifiable under the Mental Deficiency Acts. While there is reason to hope that certification of prisoners under this Act is satisfactorily carried out, it must be remembered that the conditions which make it necessary are far from ideal; as Mr. RHYS DAVIES pointed out in the debate, mental defectives should be detected before being sent to prison rather than after. He recalled the recommendation of the Departmental Committee on the Treatment of Young Offenders, that observation centres or central remand homes should be provided by the State in convenient places for the examination and observation of all young offenders. He had seen something of such work in Belgium, and was satisfied that nothing was more hopeful in the whole of Europe. He referred, of course, to the observation centre for lads at Moll, and the similar centre for girls at Namur, which are idealised remand homes where children between 7 and 21 years of age are sent for special study and classification. Under free and natural conditions each child is encouraged to reveal himself, and his particular tastes, abilities, and proclivities are ascertained. After careful individual study the treatment is prescribed—home, foster parents, State school or special institution. The beginnings of a similar system exist in England. At the Boys' Prison at Wandsworth are collected all the lads remanded from the London area, and all those who have been committed to Borstal institutions. Mr. RHYS DAVIES drew attention to the good work that was being done at this centre, where the careful medical and psychological examination of each child is supplemented by inquiries into his home circumstances by a group of voluntary women workers. Here again, as the result of these studies, some of the boys are placed on probation, others certified as mentally defective, and others sent for training to Borstal institutions at Portland, at Feltham, or near Rochester, according to their needs, for each of these institutions is specialised for different groups of delinquents.

All these institutions, both here and in Belgium, deal with the young offender as such, what time

the prisons zealously endeavour to reform the adult criminal. But the future is with the prevention of delinquency rather than with the treatment of crime, the causes of which are often to be found at a very early stage in the life of the individual. The mental health of all children, therefore, should become the intelligent care of each community; all character deviations and mental abnormalities should be early detected and early corrected to avoid the waste of good citizens and the tremendous expense of criminal repair that is our present portion. In that prophylaxis lies the hope—indeed, the purpose—of the mental hygiene and child guidance movements.

ASPHYXIA.

THERE are three principal causes of acute asphyxia: drowning, electric shock, and the inhalation of poisonous gas or vapour. The increasing ease with which town populations can reach bathing-places makes the tale of drowning accidents longer every summer; the second risk is increasing with the growing industrial and domestic use of electricity, and the third has become much greater since motor vehicles came into popular use. It is, therefore, becoming more and more necessary for the practitioner to be certain in his mind of the methods he will employ when confronted with asphyxia. Artificial respiration immediately occurs to the mind of doctor and first-aid worker alike, and the Schäfer prone-pressure method[1] has proved so successful of recent years that it has almost superseded all others. The patient's air-passages are cleared as well as possible, and he is laid prone on the floor with one arm bent and the other extended, and the face turned to the side. The operator kneels astride the thighs and places his hands on the lower ribs. He compresses the thorax by leaning forward on his straight arms, and releases the pressure by swinging back. Inspiration and expiration should last about two seconds each. So much every first-aid worker knows, but while artificial respiration is undoubtedly the corner-stone of treatment for asphyxia the doctor is properly expected to offer more skilled help than the layman, and there are other very important facts to be remembered.

Drowning, to quote a recent and able summary of the position by Dr. C. K. DRINKER,[2] is, as far as is known, a relatively simple form of asphyxia, and when the mouth and nose have been cleared of obstruction the Schäfer method is all that remains to be done. Nerve cells die at different rates when deprived of a regular supply of oxygenated blood. The small pyramidal cells of the cerebrum die, he says, in eight minutes, while the spinal cord and sympathetic ganglia may last for an hour. Complete immersion in a healthy person does not cut off the oxygen supply completely, and the chances of recovery depend on the great viability of the medullary centres. It is necessary, of course, to lose no time before starting rescue measures, but a healthy individual has a good chance if artificial respiration is commenced, even after 15 minutes. Dr. DRINKER does not recommend drugs for drowning, or indeed for any form of asphyxia. Alpha-lobelin he stigmatises as inefficacious and dangerous. Caffeine sodiobenzoate may have some effect if given intravenously, and can do no harm, but the doctor may safely leave his hypodermic case at home. When electric shock is the cause of the asphyxia, perseverance is the keynote of treatment. It cannot be too widely known that death from electricity is usually no more than apparent death. Artificial respiration should be begun immediately and continued for several hours, for no form of asphyxia yields such a good recovery-rate. Lay workers are instructed to continue their efforts for four hours; recovery is common after three hours and has even occurred after eight. Electricity may act primarily on the circulation, so that respiration continues for a few minutes after the shock and then ceases; in such patients the heart is probably in fibrillation and the prognosis is bad. Generally, however, the current paralyses the respiratory centre while leaving the circulation normal, and the patient may recover his breath after hours of apnœa. All the evidence warns us against declaring patients dead unless heart sounds and pulse are entirely absent after a long period of prone pressure respiration; they turn cyanotic and regain colour as treatment proceeds. To combat the rise of intrathecal pressure which sometimes occurs, Prof. S. JELLINEK recommends lumbar puncture.[3]

Asphyxia caused by carbon monoxide poisoning introduces an entirely different factor, as Prof. HAMILTON HARTRIDGE pointed out in a lecture reported on p. 1137 of our present issue. The asphyxia resulting from inhalation of coal-gas, motor-car fumes, or the effluent from badly ventilated gas and anthracite stoves, is chiefly due to the affinity of the monoxide for hæmoglobin, so that oxygen is excluded from the blood. This chemical effect calls for oxygen inhalation to assist the starved tissues. As the respiration is depressed in the late stages, 5 per cent. of carbon dioxide should be added to stimulate the respiratory centre. Prof. HARTRIDGE also suggested the exhibition of sodium cyanide for this purpose. Artificial respiration should, if possible, be performed with the oxygen-carbon dioxide mask in place,[4] and it is important that the oxygen be administered as early as possible, for the damage done by oxygen-want is, as we have said, directly proportional to time, and it is possible that a patient may recover from the asphyxia and yet be permanently crippled in cerebral function. It should, however, be remembered that high concentrations of oxygen are dangerous to the lungs if given continuously for long periods, and the oxygen should be replaced by air and carbon dioxide as soon as the real urgency has passed. All carbon monoxide should have left the blood after an hour and a half. Another useful way of supplying oxygen to the tissues is by transfusion, but this must be done early. Finally, a valuable hint, that does not always occur either to doctor or layman, is that the nearest gas-works will probably provide trained help and suitable inhalation apparatus more efficiently and promptly than any hospital.

THE EVOLUTION OF A HERESY.

THE heresy of one generation becomes the orthodoxy of the next. Prof. ERNST KRETSCHMER, known in this country by the translation of his work on "Physique and Character," contributes an important article to the *Deutsche Medizinische Wochenschrift* of April 13th on Further Developments of Psycho-therapeutic Technique, especially of Psycho-analysis. He begins by noting that whoever, as a bystander, might seek to form a judgment from the theoretical

[1] Harvey Lectures, 1907–1908. J. B. Lippincott Company.
[2] Jour. Amer. Med. Assoc., 1928, xc., 1263.

[4] Booklet of American Gas Association, Lexington-avenue, New York.

discussion for and against psycho-analysis that has been carried on in past years would find himself in hopeless confusion. On the one side he would see an organisation that resembled not only a scientific alliance but a religious sect, inasmuch as it expelled dissenters who in turn built up hostile daughter sects; on the other side he would see a small group of critics who, seizing upon its weaknesses and errors, too hastily reached a caustic repudiation of the whole psycho-analytic movement. This condition of affairs was, says KRETSCHMER, the reflex of the storm that productive new thoughts are wont to raise at their first appearance; but it is now becoming a thing of the past, for the younger generation of psychiatrists knows nothing of the artificial antithesis between analyst and non-analyst. As a contrast to the old theoretical discussions he points to the work of independent investigators like von BLEULER, HOFFMANN, HOMBURGER, KRONFELD, and J. H. SCHULTZ, who, starting with no blind acceptance of the views of FREUD and his school, have subjected the psycho-analytical thesis to purely empirical clinical tests with resulting judgments that trend clearly and uniformly in one direction. Whilst exercising definite criticisms of some weighty points, these authorities see in the nucleus of the Freudian method one of the most valuable foundation-stones of a modern psychotherapy, and in its fundamental results—besides untenable or too paradoxical formulations—a wealth of psychological insight as well as empirically sound knowledge of mankind. The personal experiences of KRETSCHMER and his colleagues lead to the same generalisations and are likewise productive of criticisms that arise from actual observations and bear no taint of prejudice or a priori reasoning. His own methods are eclectic and he disapproves of those who analyse "according to Freud" or "according to Adler," for he believes that whoever has at heart the good of psychotherapy and psychiatry will set forth what is valuable in the teachings of the different analytical schools, and that the important fraction of psychotherapists who still group themselves into sects must incorporate their work with the general body of medical psychology. KRETSCHMER here pictures a process of evolution that is taking place, though more slowly, among ourselves in this country. Here, as elsewhere, there has been a separation of psycho-analysis from the general body of medicine and even of psychiatry, and the separation seems to have been accepted by analysts as well as by their opponents. Although psycho-analytical conceptions, after more than thirty years of strenuous opposition, are increasingly finding acceptance outside the circle of whole-hearted Freudian adherents, and although the day of futile theoretical discussion has almost passed, yet these conceptions, it must be admitted, are not yet handled with that freedom that should characterise scientific work and without which adequate clinical discussion is impossible. If let alone this state of things would eventually right itself, but KRETSCHMER'S work indicates the need for a change in the present point of view that acquiesces in the isolation of psycho-analysis. The scope and limitations of analysis, its successes and failures, the applicability of particular methods, the use of psycho-analytical knowledge apart from actual analysis—all these and many other problems will sooner or later force themselves upon medicine and will only find solution in frank and unhampered discussion; and in the interests of psycho-analysis itself there is urgent need of that informed criticism which is the breath of life to any developing theory.

Annotations.

"Ne quid nimis."

DISABILITY DUE TO RESPIRATORY DISEASES.

OUR knowledge of the incidence of most forms of disease has for its basis statistics of mortality. Statistics of morbidity, except in the case of infectious diseases, are extremely meagre, and for many non-lethal illnesses non-existent. From the public health standpoint, but much more from the economic and industrial point of view, mortality figures may leave quite erroneous impressions as to the relative importance of various causes of invalidity and of the hygienic problems requiring most urgent attention. The "captains of the men of death" are not necessarily in the commissioned ranks of the factors which at present preclude the attainment of the highest possible level of human health, efficiency, and happiness.

In a recent issue of THE LANCET,[1] the importance of respiratory diseases, in particular bronchitis and pneumonia, as causes of mortality, and the influence and difficulties encountered in the accurate evaluation of various ætiological factors have been clearly emphasised by Miss Hilda M. Woods. The position occupied by affections of the respiratory tract among the causes of morbidity and the relative frequency of different kinds of respiratory disease causing disability form the subject of an important paper recently published in the Public Health Reports of the United States Public Health Service by D. K. Brundage.[2] The paper deals with the statistics of invalidity caused by respiratory diseases among employees of the Edison Electric Illuminating Co. of Boston, and also those collected by a group of industrial sick benefit associations. The records from the former source include all disabilities lasting one working day or longer, and are therefore of prime importance in giving us a true insight into the frequency of minor illness; the latter include only those cases of illness causing disability for eight consecutive days or longer. It was found in this investigation that, roughly, half of the total number of absentees and half of the total time lost by employees were due to respiratory illnesses. The common cold, which accounts for 71 per cent. of the total diseases of the respiratory system, is by far the worst offender, being six times as common as tonsillar and pharyngeal affections, eight times as frequent as influenza, and more than 20 times as frequent as bronchitis. In spite of the shorter average duration of invalidity resulting from colds, the great excess of cases of this condition puts it an easy first in the causation of the total number of days lost in industrial employment. Practically all cases of colds are of less than eight days' duration, as is seen when the records of sick benefit associations, which exclude illnesses of less than eight days' duration, are examined. In this collection of data common colds entirely drop out of the morbidity picture. The difference between the total annual absence rate of 564 per 1000 men, and the absence rate of 43 per 1000 due to illness lasting eight consecutive days or longer shows how vast a proportion of all respiratory diseases last for a week or less. The seasonal variations in mortality from affections of the respiratory tract are almost parallel to those of morbidity, in which the minimum occurs in July and a maximum in February. A point of some interest is revealed by a comparison of the seasonal curves of all respiratory illnesses irrespective of duration and of those lasting for eight days or more. From this it would appear that attacks of respiratory sickness having their onset in late winter and early spring tend to be more prolonged than those which

[1] Woods, H. M.: THE LANCET, March 17th, p. 539.
[2] Brundage, D. K.: Public Health Reports, U.S. Health Service; March 16th.

begin in the early part of winter. This observation may be taken to represent a lower degree of resistance to respiratory infections among industrial workers towards the end than at the beginning of winter. The seasonal variations in the incidence of common colds and influenza are much greater than in either diseases of the pharynx and tonsils or bronchitis and pneumonia. As in the mortality statistics presented by Miss Woods, so also in these morbidity statistics, one of the striking features of respiratory diseases is the great geographical divergence in the rates of incidence. These wide differences both in frequency and severity demand adequate explanation before successful prevention or control can be expected. These statistics show very clearly how relatively infrequent are the fatal forms of respiratory disease, and that the apparently trivial disability, the common cold, not in itself dangerous to life, is yet the disease probably most inimicable to national prosperity.

SEPTIC INFECTION IN A MATERNITY HOSPITAL.

AN unusually conclusive and satisfactory investigation into the causation of a curious epidemic occurring in a maternity hospital is recorded by Dr. R. Marshall Allan, Director of Obstetrical Research, University of Melbourne, and Dr. Lucy M. Bryce.[1] In July of last year Dr. Allan was requested by the medical officer of health of a Melbourne municipality to look into the circumstances surrounding the deaths of a mother and two infants and a serious infection of a third infant, all of whom had been inmates of a private maternity hospital of high standing. Six practitioners had brought the matter before the municipal authority, and the matron of the hospital had agreed to refuse admission to patients until the investigation was completed. The maternal death had occurred two months after delivery which took place on April 9th, 1927, in a woman whose early puerperium was normal. She was allowed up, in the private hospital, on the twelfth day after delivery and on the fourteenth developed a temperature of 103° F. and a pulse-rate of 100. Four days later (April 27th) the temperature was 105° F. and the pulse-rate 120, and the patient was sent away to the Women's Hospital acutely ill and semi-delirious, with abdominal pain, but no tenderness or rigidity. Hæmolytic streptococci were isolated from the blood, and in spite of injection of mercurochrome and a blood transfusion death supervened on June 4th, 1927. Post mortem, the uterus was found to be small, the appendages apparently normal, and no sign of thrombo-phlebitis in the pelvis could be detected.

The room occupied by this patient when at the private maternity hospital was disinfected and the mattress destroyed; no other patient was admitted to it until five weeks after her removal, after which it was occupied by two mothers recently delivered, and their infants. One of the infants (G.), though discharged apparently well 12 days after birth, developed a swelling of the vulva associated with inguinal adenitis; over 40 abscesses formed in various parts of its body, but eventually it recovered. Another infant (N.), born a week later than G. and nursed in the same room, developed a swelling of the right ankle and cellulitis of the thigh, and subsequently died. A third infant (M.), born three weeks after N. and housed in a different room, died five weeks after birth from septic infection. On bacteriological examination of the blood cultures taken from the woman patient, a hæmolytic streptococcus was found, and an organism showing similar and rather unusual characteristics was recovered and isolated in pure culture from one of the abscesses occurring in infant G. Material from the other infants was not available, but a report was received that examination of the pus from one of them (N.) revealed streptococcal infection. The next step in the investigation was a search for a carrier of virulent streptococci among the five doctors and four nurses who were considered to be possible sources of infection. From the naso-pharynx of one of the nurses an organism was obtained which was identical in cultural and morphological characteristics with the strain of streptococcus isolated from the patients. Descriptions in tabular form of fermentation tests and of mouse inoculations are given; there seems to be no doubt that the organism was highly pathogenic. The nurse, on further examination, was found to have pus in the left maxillary antrum, which was evacuated, and the organism was recovered also from this material. She was suspended from duty pending further examination and treatment.

Most interesting questions arise in connexion with this epidemic. Inspection of the hospital and the methods in use revealed no defects in management or aseptic technique. The previous case records were entirely satisfactory. The nurse had been in constant contact with obstetric patients and babies in the same hospital for four months, but no septic infections occurred prior to those under investigation. The possibility that patient and nurse were infected from a common source is regarded as unlikely since there was no history of acute onset or of symptoms in the relevant period. As to the mode of infection of the woman patient, this remains obscure. The omission to which the authors themselves draw attention, to take intra-uterine or cervical cultures from this patient, is regrettable on this account. The lateness of the onset of the septicæmia in the case points to a puerperal rather than an intra-partum infection. Even more puzzling than the channel whereby the organism gained entrance to the body is the escape of other women who were in the charge of the same nurse from either intra-partum or puerperal infection. The nature and mechanism of defence against infection during and after parturition is a subject on which our knowledge is still very limited, and anomalies such as are revealed in this careful study are likely to carry us further than investigations confined to local pathological conditions of the breast or uterus.

[1] Medical Journal of Australia, March 31st, p. 390.

READING AND SPELLING.

THE condition known as word-blindness, a more or less complete inability to learn to read and to spell, comes occasionally under the notice of practitioners, particularly those engaged in school services. The original idea that it was a form of feeble-mindedness was soon abandoned in favour of Hinshelwood's suggestion that it was due to a congenital defect or development of a small area in the temporal lobe of the cerebrum—a theory which has become generally accepted in medical circles. Dr. Samuel T. Orton of Ohio, who has made many studies of speech defects, throws out a new theory. The weakness of the accepted view, he holds, lies in the fact that no necropsy reports are yet available, and that the parallelism of symptoms found in cases of congenital word-blindness and in those of acquired word-blindness does not necessarily prove similarity of lesions, since destructive lesions of the speech zone do not prevent acquisition of speech, other areas being apparently allotted to the purpose. He made a special survey of 15 cases whose backwardness in reading was very marked, as compared with their progress in other subjects and their general intelligence. Their intelligence quotients, measured on the Stanford scale, ranged from 71 to 122 in spite of the special difficulty with certain tests caused by the reading disability. They all had normal vision and could easily call up visual memories of objects and pictures. The failure was in the associative linkage between words visually presented and the corresponding concept. Now it has been found that, at the associative level of the cerebrum, destruction of one hemisphere may cause loss of the associative function and inability to read (acquired word-blindness), while

[1] Jour. Amer. Med. Assoc., 1928, xc., 1095.

destruction of the other hemisphere does not produce this result. Visual records of only one side are used in symbolic association. Yet the inactive side is as well developed as the other, and must have been "irradiated equally with the active." This would leave some record in the cells of the inactive side, an engram which would be opposite in sign and would form a mirrored pattern. May it not be, then, Dr. Orton asks, that while normally only one of these paired engrams is in activity, in these abnormal cases under consideration the habit of suppression of the other engram has not been established and hence the difficulty in differentiating between "p" and "q," and "d" and "b," "was" and "saw," and the tendencies to mirror-reading and mirror-writing which he found in his cases to be characteristic of the condition? The theory is fascinating, but not quite convincing, apart from the difficulty of proving it, which is as great as in the case of the theory it is proposed to supplant. The possibility of its truth depends upon the correctness or otherwise of Dr. Orton's claim that the "tendency to reversal in the direction of reading" is the cardinal factor of the condition. The confusion of letters like "p" and "q" is one which probably few children escape at an early stage, and mirror-writing has been a well recognised curiosity of development, usually of short duration, in many normal children, and of longer duration in some feeble-minded children. These facts may seem to support Dr. Orton's theory that the condition which he names strephosymbolia is a physiological variant, but mirror-writing does not appear to have been a factor in some recorded cases of word-blindness. He admits that only one of his 15 cases "fits the measure" of Hinshelwood's congenital word-blindness, and his estimate that 2 per cent. of school-children are affected with strephosymbolia confirms the suspicion that he includes cases that do not even approximate to word-blindness, which has in England been estimated to occur in 1 out of 2000 children. The mirror-engram theory also fails to explain the difficulty with other letters and words, a difficulty which Dr. Orton somewhat cursorily sets aside as of slight importance. Certain new training methods based upon the theory are being carried out upon some of the children; the results of these, when they are available, should be of much interest.

PSYCHOLOGY OF ANÆSTHESIA.

IN a lecture recently delivered at the Royal Dental Hospital [1] Dr. Dudley Buxton discussed the psychological aspects of anæsthesia, a matter as obscure and little studied as it is practically important. If the essential causes of difficulties and dangers that arise both in early and in late stages of narcosis were better understood it would probably be found that the root of the trouble is often psychological and not physical. Every anæsthetist is familiar with some of the phenomena that may arise through what is spoken of as the "mental" or "psychological" disposition of his patient. The anæsthetist knows that an abnormal reflex activity even during deep narcosis, or an extraordinary amount and degree of excitement in the light stages, may characterise the unconscious state of the "temperamental" patient. In other subjects of the same kind narcosis may leave a peculiar and abiding effect, so that for weeks or months after its induction the patient's ordinary sleep is attended by vivid and distressing dreams which were first originated by the inhalation of an anæsthetic. Dr. Buxton alludes to the well-known instances in which shock, even fatal shock, has occurred at the beginning of an administration, even before any anæsthetic at all had been inhaled by the apprehensive subject. It is very plain, therefore, that what is called the "psychological" side of anæsthesia has a direct and powerful influence on the effects of anæsthetic administration, and this influence is possibly even more determinant when a local analgesic is employed than when there is unconsciousness. It is, however, the play of the "psychological" factor during unconsciousness that is so interesting, so dominating, and, further, so hard to investigate. Animal experimentation is here likely to be of little guidance as to human behaviour, for we are dealing with that very part of the organism in which the higher is most differentiated from the lower animal. Subjective evidence, too, is only partially reliable, for the memory of what has taken place when the brain was still under narcotic influence is necessarily imperfect.

[1] British Dental Journal, 1928: XLIX. 405.

IS THERE A RACHITOGENIC DIETARY FACTOR?

WE are accustomed to think of rickets as a deficiency disease brought about by a lack of vitamin D or by an insufficiency or unbalance of the calcium and phosphorus in the diet. E. Mellanby (1925,[1] 1926 [2]) believes that there is, in addition, a substance, occurring chiefly in cereals, the presence of which renders the foodstuff containing it actively rickets-producing, and that when the substance has been removed the same diet has no ill-effects. P. M. Holst (1927 [3]) adduces evidence in support of Mellanby's idea. He shows that rats develop rickets when they are fed on an exclusive diet of oats or yellow peas, or wheat or rye, or barley or maize, or polished rice. Pure starch does not produce the effect; rats are able to live on it for some time, and develop only an osteoporosis. An addition of casein and lard makes the animals live longer and grow, and rickets is not produced, but when the casein and lard are added to the diet of pure oats or other pure foodstuffs rickets is not prevented. Holst found that he could extract the rachitogenic substance by boiling oatmeal with a dilute solution of hydrochloric acid; the extract, when filtered and neutralised and given to rats, in a daily dose corresponding to 15–20 g. of oatmeal produced rickets in rats on the pure starch diet. The substance is organic since the ash of oats does not possess the rickets-producing power; it is dialysable and can be precipitated with alcohol, but Holst's results are not entirely in agreement with Mellanby's as to the physical and chemical behaviour of the rachitogenic substance.

Recently A. F. Hess and M. Weinstock (1927 [4]) have made the startling suggestion that cow's milk contains a rachitogenic substance and that the more of the milk an infant receives the more likely it is to develop rickets. Much in their paper is unsupported assertion: they state, for instance, that an infant of six months, receiving a quart of milk, is more likely to develop rickets than one of the same age receiving a pint, but they bring no figures in support of the statement, nor do they dispose of the objection that an infant of six months, receiving only a pint of milk would be under-caloried. Rickets is a disease which requires active growth, in order to show itself in a florid form, and growth is unlikely to be active if the supply of calories is much too low. As to details, Hess and Weinstock start with the premiss that human milk is more preventive of rickets in the human infant than is cow's milk, because they have found that in new York, in March, all bottle-fed infants, unless they have received some special specific therapy, are suffering from some degree of rickets. Only one-half to two-thirds of the breast-fed infants are found to suffer in this way. Hess and Weinstock, therefore, set out to discover whether the difference is due to the superiority of human milk in the antirachitic factor. When they tested the antirachitic value of cow's milk and of human milk on rats, they found that 20–25 c.cm. of the former were needed to prevent rickets, while 25–30 c.cm. of human milk were needed. This result showed that the human milk tested was of very poor antirachitic potency for rats, whereas Hess and Weinstock make

[1] Med. Res. Council Special Report Series No. 93.
[2] Proc. Phys. Soc., Jour. Physiol., 1926, lxi.
[3] Jour. of Hygiene, 1927, xxvi., 437.
[4] Amer. Jour. Dis. Child., 1927, xxxiv., 845.

the assertion that breast milk is of high antirachitic potency for infants. They therefore conclude that "the high protective value of human milk in infantile rickets cannot be ascribed to its content of the antirachitic factor." If it were due to abundance of the antirachitic factor, they argue, rickets would have been prevented in rats, in a smaller dosage than that found necessary. When they made experiments on rats with the cream of cow's milk, they got into yet more difficulty. They used 20 per cent. cream and top-third milk, but they did not get as good results with the top milk as with the cream, although the doses of fat given were supposed to be identical. From this slender piece of evidence Hess and Weinstock conclude that there is an actual rachitogenic factor in the skim fraction of the top milk, which offsets the antirachitic value of the cream contained in it, and presumably accounts for the inferiority of cow's milk to human milk for the prevention of rickets in human infants. The animal experiments are very few in number, and if such an important conclusion was to be drawn from them it would have been advisable to supply actual estimates, showing that the same amount of fat was given to both sets of rats.

The conclusions which Hess and Weinstock draw may be correct, but evidence is lacking that their whole premiss, that human milk is so much superior, is not false. They tell us that all the infants on cow's milk and a large proportion of those on breast milk get rickets. Some breast milk is therefore superior to cow's milk as an antirachitic for infants, but some from their own admission, is not. Clinical evidence should certainly have been included to show that the breast milk tested on rats was derived from the mothers of non-rachitic infants, and not from the mothers of rachitic ones, who admittedly existed in the community in large numbers. Hess is too well known a pediatrician for this communication to be disregarded, but the reasoning is difficult to follow, and some of the necessary data have not been published. The evidence offered is certainly not sufficient at present to warrant the inclusion of milk among the substances which contain a positive rachitogenic factor, but evidence seems to be accumulating that cereals do contain such a factor.

NORMAL VARIATIONS IN THE CEREBRO-SPINAL FLUID.

IT must be admitted that the examination of cerebro-spinal fluid is often disappointing. The pathologist feels that he should be able to do more with what has been so hardly won; was not the first clinical sample obtained by laminectomy? The specific changes are rather few, and if we agree that the fluid varies within the limits normally stated, many organic lesions of the central nervous system seem to leave it unaffected by their presence, and therefore of but little use in diagnosis. Greater precision is desirable if possible, and Dr. Axel Neel[1] has therefore done a service in analysing 6000 successive cases in which the C.S.F. was examined. He finds—and most pathologists will agree with him—that the normal maximal number of cells per cubic millimetre is not, as conventionally stated, five, but is in fact not more than one. Moreover, his 800 normal cases never showed a total albumin value (as estimated by the Brandberg-Stolnikow-Bisgaard method) exceeding seven, and it rarely exceeded six. In order to count cells with such accuracy, a chamber of exceptional depth and area is necessary to obviate errors of multiplication. Dr. Neel claims that he was unaware of the clinical diagnosis until after the examination of the fluid; but he was, perhaps, a little fortunate in never coming across those specks of dust, epithelial cells, or even red blood cells, or blood leucocytes from needle trauma which worry other pathologists, and might have ruined his series. He finds the gold-sol test of no differential value; here again most observers will agree with him. Pandy's test, in which C.S.F. is dropped into saturated aqueous phenol, he regards as the most reliable crude test for excess globulin. He rightly insists that much useful information may be lost by failing to do accurate counts and accurate albumin estimations. Particularly is this true in the differential diagnosis between hysteria and organic lesions of the central nervous system. It is remarkable what a large proportion of syphilitic patients without clinical nervous lesions fall just outside normal values both in cell count and albumin content. Of late there has been a tendency among physicians to demand quantitative instead of qualitative estimations of C.S.F., and there is no great difficulty in meeting the demand. There is, however, no Fuchs-Rosenthal counting chamber of adequate dimensions on the English market at present. Dr. Neel's chamber has double the usual volume.

IMPACTION OF THE WISDOM TOOTH.

THE reason why the third molar tooth is so apt to lead to trouble in the lower jaw is that the mandible is rarely large enough to accommodate this tooth even when it is normally situated, and the lack of room leads frequently to its misplacement. When the eruptive impulse results in impaction against the tooth in front, infection in the bone and soft tissues is likely to ensue, and the position of the tooth favours the spread of such infection along cellular planes backwards, downwards and upwards, into dangerous areas. The lay public is so ready to attribute any pain or swelling of the upper or lower jaw in adult life to a wisdom tooth, however that practitioners are apt, after glancing into an apparently normal mouth, to search for less obvious sources of pressure or inflammation. In the lower jaw especially, however, attempted eruption of the third lower molar can give rise to most unpleasant results, and superficial inspection without a radiogram is not sufficient to exclude its presence in an abnormal or impacted situation. The dangers of neglect to take a radiogram are exemplified by two cases recently described by E. Polloson and M. Dechaume in the *Presse Médicale*.[1] The first case was that of a girl of 18, who had a large swelling at the angle of the jaw accompanied with much pain. The condition had existed for over a year. There was no history of inflammation and the growth, at first soft, had become progressively harder. A surgeon diagnosed a periosteal sarcoma of the mandible; he operated and removed a large mass of fibrous tissue which, when examined microscopically, showed no signs of malignancy. The wound healed well, but the swelling soon returned, increased in size and invaded the mouth, leading to trismus. Radium was applied intrabuccally but with no result beyond that of causing ulceration of the mucosa followed by the establishment of a discharging sinus at the base of the coronoid process. The surgeon advised further operation of a more extensive character but, fortunately for the patient, at this stage a radiogram was taken. The alveolar plates of the mandible were seen to be expanded and lying between them was a deformed, unerupted third molar. In the maxilla, on the same side, both the second and third molars were misplaced, so that normal eruption was impossible. It was evident that the swelling and trismus were due to infection round these teeth. The patient came under the care of Prof. Tixier, who operated and with much difficulty removed the impacted teeth. The trismus and swelling speedily subsided, though some permanent deformity remained. The second case recorded was equally instructive. A woman of 58 had suffered from excruciating attacks of facial neuralgia on the left side for over 20 years. The slightest draught brought on an attack and the patient spent most of her time in bed in a warm atmosphere. In 1924 the neuralgia became more

[1] A propos des accidents graves liés à l'éruption vicieuses la Dent de Sagesse, Presse Médicale, April 11th.

localised and seemed to arise from the left side of the mandible. Gradually a swelling manifested itself at the angle of the jaw accompanied by signs of inflammation and leading to a progressive trismus which eventually became complete. The patient was by this time very emaciated and her mouth extremely foul. At this stage, for the first time, a radiogram was taken; it showed a lower third molar lying almost horizontally, a zone of rarefaction round it indicating the existence of a chronic osteitis. Under general anæsthesia Prof. Tixier made an external incision and removed the tooth. Both neuralgia and trismus completely disappeared. These cases illustrate the wide variety of clinical signs which may follow impaction and infection of third molar teeth. In neither was the dental origin of the condition at all obvious, nor could it be easily inferred from the history or the physical signs. If a radiogram had been taken at any early stage the girl could have been spared a mutilating operation and the mental anguish consequent on the belief that she had malignant disease; the woman could have been cured earlier of the neuralgia which had crippled her life for 20 years.

NOTIFICATION OF VENEREAL DISEASE IN NEW SOUTH WALES.

IT is difficult to draw solid conclusions from the recently published report of Dr. Robert Dick, the Commissioner under the Venereal Diseases Act in New South Wales. The report is included in the annual report of the Director-General of Public Health and deals with the year 1926. During that year there were 6001 notifications, an increase of 687 on the number notified in 1925. The increase is attributed to the issue of a circular to medical practitioners at the end of 1925, directing attention to their legal responsibilities and duties under the Act. The Act intentionally placed the duty of notification upon the doctor. Dr. Dick seems to think that his statistics are incomplete for reasons which are familiar in this country. Some medical practitioners think notification inherently futile or at least useless as a precaution; some find it too much trouble; some act as if "the least said the better." The statute provides that notification shall be by number not by name. Even the address of the patient is withheld, but if he fails to continue under treatment until cured, it is provided that his name and address shall be forwarded to the Commissioner for necessary action to ensure resumption of treatment. Here the figures are instructive. During 1926 the Commissioner thus received the names and addresses of 1060 patients who had defaulted from treatment. Of these 280 resumed in response to representations, 187 cases were still under investigation at the end of the year, and the rest (the majority of the total) could not be traced. Of course, as Dr. Dick suggests, many may have been visitors from overseas, from other States, or from country districts, and may be under treatment elsewhere. Still it is hard to resist the conclusion that in Australia, as in this country, patients are prone to give false names and addresses. The proportion between the sexes remained roughly the same in syphilis notification in 1926 as in previous years—namely, about 3 males to 1 female. There was a difference in the proportion in gonorrhœa; for 1923, 1924, and 1925 it had been roughly 10 males to 1 female; in 1926 the ratio was 7·84 males to 1 female. The New South Wales statistics clearly confirm the fact that venereal disease is a problem of large cities. The notification figures are striking in this point. The metropolitan area with a population of little more than 1,000,000 accounts for over 5000 notifications. The rest of the State with a population of scarcely 200,000 more had only 387 notifications. Dr. Dick does not think that venereal disease is spread in Australia by commercialised vice. Professional prostitution does not exist on a large scale, but there is sexual promiscuity in the big cities where people find themselves free from gossip and criticism and where they go to have a good time and spend their money. Perhaps the most disquieting feature in the report is the rise in the number of female children and young girls suffering from gonorrhœa. The total of these in the age-group up to 20 years was 135 in 1924 and 153 in 1925, but in 1926 it rose to 268.

SURGICAL DIATHERMY OF THE TONSILS.

REMARKABLE differences of opinion are to be found in the published literature concerning the use of diathermy for removal of tonsils. On the one hand, G. B. Massey [1] states that "the consensus of opinion of those applying the method skilfully is that these applications should replace tonsillectomy in the great majority of cases," while, on the other hand, Novak [2] considers that "the very severe reaction, the great pain, the toxæmia, and the extreme discomfort of the patient, are sufficient reasons for condemning the method." In a moderate and well-considered review of the subject, Dr. E. W. Frecker [3] comes to the conclusion that this difference of opinion is due, as might well be expected, to difference of technique. He believes that the bad results arise from the use of too heavy a current for too long a period, and from the employment of too large an electrode; and he is of opinion that the reaction cannot be sufficiently limited by the ordinary method of bipolar coagulation, and that a button electrode should never be used in these cases. Dr. Frecker claims that the monopolar method, often termed electro-desiccation, and causing drying of the tissues over a very limited area, is far more suitable for the treatment of tonsils, and describes the technique. As electrode a needle is used, insulated by a rubber-covered glass tube, so that only $\frac{1}{4}$ in. projects for insertion into the tissues. Applications are made once a week, to each tonsil alternately, about six sittings being required. Anæsthesia is secured by painting the region with a 10 per cent. solution of cocaine, and it is said that the treatment is almost free from pain both at the time of application and afterwards. The needle is inserted for $\frac{1}{8}$ to $\frac{1}{4}$ in., the current is applied until a white ring appears, and the process is repeated until the whole of the tonsil is white, which entails 12 or 15 punctures, according to the size of the organ. If any bleeding should occur, it is checked by raising the electrode from the surface and allowing the current to spark on to the bleeding spot. The after-treatment is to use a simple mouth-wash; the reaction, says Dr. Frecker, is limited to a little soreness on the next day, and the sloughs come away piecemeal without trouble; the result is an undistorted fossa, without sign of fibrous tissue or contraction. The method is not suitable for children, but is indicated for hæmophiliacs and for those whose state of health makes tonsillectomy dangerous.

THE Croonian Lectures of the Royal College of Physicians of London will be delivered at the College at 5 P.M. on Tuesday the 5th, Thursday the 7th, and Tuesday the 12th of June by Dr. Charles Bolton. His subject will be "The Interpretation of Gastric Symptoms."

THE death occurred on May 28th, at the age of 86, of Dr. George Edward Shuttleworth, for many years medical superintendent of the Royal Albert Institution, Lancaster, and the author of numerous works on mental deficiency.

Dr. Abraham Flexner, who recently delivered the Rhodes Memorial lectures at Oxford, has resigned his position as Director of Studies and Medical Education of the General Education Board of the Rockefeller Institute. He proposes to devote his time to writing on university education in Europe and America.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXVIII.

TREATMENT OF CANCER OF THE BLADDER.

It is fortunate that cancer of the bladder is comparatively rare, as there is no organ in the body where malignant disease gives rise to more intense suffering. Vesical neoplasms only form about 0·5 per cent. of all new growths, and about half of them are malignant. Approximately two-thirds of the bladder tumours are found in the male, the age-incidence being 50 to 70. A large proportion of vesical carcinomata arise from villous tumours of the bladder which have undergone malignant degeneration. It is probable that most of these growths ultimately become malignant if untreated, but in a few instances removal of an apparently benign growth has been followed by a definitely malignant recurrence. I have never seen this type of recurrence when the original growth was fulgurated.

Several types of cancerous tumours are found in the bladder. They are the villous carcinoma, the scirrhus, the squamous-celled, and the adeno-carcinoma. Of these the scirrhus form is in my opinion the most malignant. The villous form, when malignant from the start, and not the result of changes occurring in a papilloma, is likely to remain localised for a considerable time, and the operative results are good.

The postero-lateral wall is by far the most common site for all tumours of the bladder. The next most common site is the anterior wall, while they are comparatively rare on the vault. Recurrences are located at the site of the original growth, in the suprapubic scar, or in the aveolar tissue of the pelvis.

Changes in the kidneys and ureters are mechanical and infective. If the tumour compresses the lower end of the ureter the kidney and the upper part of the ureter become dilated from back-pressure. A hydronephrosis or a pyonephrosis is formed according as the urine is sterile or infected. Once cystitis sets in the patient is liable to attacks of ascending pyelonephritis, which may prove fatal. Renal infection is in my experience the most common cause of death after operation.

Symptomatology.

It is impossible to distinguish between the symptoms of a benign and a malignant tumour of the bladder in the earlier stages. It is only when the bladder is infected and the growth advanced that distinguishing symptoms appear. The first and most common symptom is an intermittent, painless hæmaturia. As a rule it lasts for two or three days, and then gradually the urine becomes clear, remains so for weeks or even months, when a similar attack occurs. As a rule, during the earlier attacks the blood is fluid; if clots are found they are small. If the hæmorrhage is profuse, larger clots form, which give rise to pain and difficulty in micturition, and even occasionally to complete retention. In this case they must be washed out through a large catheter, and if this is impossible a suprapubic cystotomy must be performed. The hæmaturia is always terminal; that is, more blood is present in the last portions of urine passed than in the first, and this test serves to distinguish between a vesical and a renal hæmaturia. The presence of large numbers of epithelial cells from the bladder in pus-free urine is highly suggestive of a neoplasm.

Sooner or later cystitis sets in and entirely changes the clinical picture. There is then marked frequency of micturition both by day and night. The act is always extremely painful, the pain increasing in intensity till it culminates in a particularly painful spasm when the bladder is empty, and a few drops of blood are expelled. The bladder capacity is much reduced. As a rule there is no difficulty in micturition unless clots are passed. In the later stage the urine becomes blood-stained and is very foul. It is not usual to find recognisable portions of the tumour in the urine in malignant tumours, although they are frequently observed in benign growths.

Although hæmaturia is a prominent symptom in most cases of vesical carcinoma, blood is sometimes present only in microscopical quantities. A chronic relapsing cystitis is highly suggestive of malignant disease of the bladder, and cystoscopy should not be unduly delayed in these cases.

In the later stages of cancer of the bladder the patient's general condition rapidly deteriorates. Death is usually due to exhaustion or pyelonephritis. If the growth is malignant from the start the duration is often less than a year, and rarely longer than two years. When a benign growth takes on malignant characters the duration of the disease is increased.

Diagnosis.

The diagnosis can only be made by cystoscopy while the patient is still in the operable stage. If the growth is palpable, either on hypogastric palpation or on bimanual examination with a finger in the rectum and the other hand pressing the abdominal wall downwards, it is inoperable. Occasionally an operable growth can be felt on vaginal examination, but in the male a palpable growth is always inoperable. Early cystoscopy is the only means of reducing the proportion (now over 60 per cent.) of growths inoperable when first seen.

The cystoscope enables one not only to determine the presence of a vesical tumour, but also its position and nature, and in most cases its operability. If long and thin villi are easily set in motion by currents in the fluid contained in the bladder, and the whole growth is moveable, it is almost certainly benign. If the villi are short and thick, the stalk thick and rigid, and the whole growth fixed, it is definitely malignant. Irregular puckering, or nodules, appearing in the mucous membrane surrounding the base of the growth are indicative of a submucous infiltration. It is often exceedingly difficult to detect early malignant changes, and if there is any doubt, it is safer to assume that the growth is malignant.

A malignant tumour involving the internal meatus is usually unsuitable for operation: a growth—one situated on the postero-lateral wall—can be removed as a rule provided there is sufficient margin of healthy tissue between it and the internal meatus; resection, and reimplantation of the ureter, does not materially increase the risk. If the growth involves both ureteric orifices, operation is contra-indicated. Large growths can be removed from the vault or anterior wall of the bladder.

Nodular growths are much more liable to infiltrate the bladder-wall laterally than the villous type. As a rule operation is unsatisfactory if the growth is more than 2 in. in diameter at its base.

The cytoscope gives no indication if the growth has spread into neighbouring organs, or is involving the lymphatic glands. The first step in the operation is thus always exploratory.

Operative Measures.

The best method of treatment is excision. This involves an extensive resection of the whole thickness of the bladder-wall. The large gap left is closed by a line of continuous sutures passing through the whole thickness of the bladder-wall.

If the growth is situate near the ureteric orifice, the space between the bladder and the lateral wall of the pelvis is first explored. If the glands along the course of the internal iliac artery are enlarged, hard, and matted together no operation can cure the patient, but if they are only slightly enlarged, and still soft, the operation should be proceeded with. The ureter should be isolated, and a strip of gauze passed round it for future identification. The bladder is then opened, and the growth encircled by an elliptical incision. Any bleeding points are clamped and tied. The large gap in the bladder wall is then sutured from below upwards by means of a continuous catgut suture; this procedure is not easy to carry out. The upper end of the ureter is either implanted into the incision, or is brought through a small puncture in the bladder-wall and sutured in place. Both the bladder and the pelvis

are drained. After these large resections the cavity of the bladder appears to be very small, but it soon recovers its normal capacity.

Total cystectomy is rarely performed; not only is the disposal of the ureters a difficulty, but if the growth is too extensive for excision the lymphatics are already involved, and the operation is followed by a retro-peritoneal recurrence.

Palliative Measures.

Even when the lymph glands are involved, a resection may relieve the patient entirely of his bladder symptoms, and he may live the remainder of his life in comparative comfort. If the growth cannot be resected, it may be destroyed by diathermy, applied through a suprapubic opening. Radium seeds should then be implanted round its margin. The disadvantage of this operation is that the sloughs may take a long time to separate, and the suprapubic fistula may have to be kept open for several months. The implantation of radium into the growth may be followed by a diminution in the amount of hæmorrhage and a slight amelioration in the patient's symptoms, but I have never succeeded in causing the complete disappearance of the neoplasm. I have only employed radium in advanced and quite inoperable cases; it forms a useful adjuvant to diathermy. I have twice seen recurrences in the abdominal wall entirely disappear under deep X ray therapy, but I have not seen any successes when the growth was actually in the bladder. If deep X ray therapy is employed, the patient's blood should be examined at frequent intervals; if the polymorpho-nuclear leucocytes fall to 2000 per cubic millimetre, the treatment must be stopped. A suprapubic cystotomy does little to relieve pain. The chief indication for this operation is severe hæmorrhage with clot retention. A certain amount of relief may be obtained by turning both ureters out on to the skin, so as to deviate the urine.

Medicinal Measures.

The pain of advanced vesical carcinoma is intolerable, and can only be relieved by morphia. A suppository of morphia and belladonna should be given every night, and a mixture containing hexamine and tincture of hyoscyamus taken in the day time. Hexamine is the best urinary antiseptic provided the urine is acid. If it is alkaline the reaction is usually due to the presence of a urea-splitting organism. In this case it cannot be rendered acid by the administration of acid sodium phosphate or other drugs, and either sandal-wood oil, or hexyl-resorcinal should be substituted for hexamine. Most patients cannot stand bladder irrigation; it usually increases the vesical irritability, but if it can be tolerated it helps to keep down sepsis. Dilute solutions of silver nitrate (about 1 in 10,000) are most efficacious, but if this cannot be tolerated, boric lotion should be substituted for it. Injections of small amounts of antiseptic fluids into the bladder are better tolerated than irrigations. About 5 cubic centimetres of a 20 per cent. solution of gomenol in oil may be injected every other day through a small soft catheter, and left in the bladder. The patient should have a plain easily digested diet. Alchhol, spices, and condiments should be forbidden. Plenty of bland fluids, such barley-water, Contrexèville or Vittel water, &c., should be taken. It is a mistake to restrict the intake of fluid, for micturition is usually less painful if the urine is dilute.

Results.

The operative mortality following resection is about 10 per cent. In my own cases it was nil when the bladder was not infected, and 12 per cent. when infection was present, but as the latter cases greatly exceeded the former, the total mortality was approximately 10 per cent. The late results are surprisingly good. Sir J. Thomson-Walker has found, on following up his cases, that over half of them remained free from recurrence, some for as long as 15 years.

CARBON MONOXIDE GAS POISONING.*

BY H. HARTRIDGE, M.D., SC.D., F.R.S.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON.

1. *How Carbon Monoxide Gas produces Poisoning.*

Carbon monoxide (CO) poisons by chemically combining with the hæmoglobin within the corpuscles and thus reducing the oxygen-carrying power of the blood. It also probably combines with the hæmoglobin present in muscle. The effects of this are not known. It has been proved in high concentrations to affect the action of certain oxidising ferments in some seeds and insects. It is not known whether it produces similar effects in man. It is thought by some authors to have a specific action on the central nervous system because of the intensity of the headache and dizziness.

2. *The Acute Symptoms of Carbon Monoxide Poisoning.*

These are in a mild case, increased circulation rate; increased depth and rate of respiration; headache and dizziness; nausea (sometimes vomiting); muscular weakness; dilated pupils, and a flushed face. In a severe case the symptoms are decreased circulation-rate; loss of consciousness; convulsions, and a pale face. In a fatal case they are usually stoppage of respiration followed by stoppage of the heart. During the mild symptoms the oxygen want produced by the carbon monoxide is compensated (*a*) by increased circulation-rate; (*b*) by increased lung ventilation; (*c*) by vaso-constriction in viscera and muscles (shown by nausea and muscle weakness). This vaso-constriction is probably partly nervous due to the vaso-motor centre, and partly chemical due to adrenalin in the blood; this also causes the large pupils.

3. *The Amount of Carbon Monoxide in Air which Produces Poisoning.*

There is no definitely fatal amount of carbon monoxide (CO) in air since pure carbon monoxide gas could probably be breathed for a very short time without causing any symptoms. The evidence available indicates that two factors are concerned: (*a*) the quantity of carbon monoxide in the air, and (*b*) the time during which this air is breathed. (Tables I. and II.)

0·135	20·5	66
0·18	29·5	72
0·30	36·6	81
0·60	53	90

15 per cent. CO in blood caused noticeable throbbing in the head. Headache and nausea above 25 per cent. approximately. Loss of consciousness at about 53 per cent. Roughly if the CO percentage in air multiplied by time of exposure in minutes equal 1 there may be just noticeable symptoms (and there may be about 10 per cent. CO in blood) (see Table II.). If, when multiplied together they equal 5 mild symptoms may

* Based on a lecture delivered on May 17th at St. Mary's Hospital Institute of Pathology and Research.

be replaced by severe ones (and blood may be about 30 to 40 per cent. saturated). Mice and other small animals killed by coal gas are usually found to have about 80 per cent. CO in their blood. In a fatal case in which a chauffeur was poisoned by a car exhaust, the blood was stated to contain 58 per cent. CO.[3] A given percentage of CO in air is more dangerous to men performing active work than to men at rest. It is also more dangerous to men respiring deeply than to men with shallow breathing. It is also more dangerous to mammals with a high metabolic rate than to mammals with a low—i.e., babies may be more susceptible than adults.

4. *Carbon Monoxide in Coal Gas.*

The danger of poisoning is partly due to the carbon monoxide gas, which varies. Values between 9 per cent. and 18 per cent. are common. The smell of coal gas, which may act as a warning of its presence, cannot be always relied on, for the following reasons: (1) some people cannot smell it at all; (2) the olfactory mucous membrane tires, thus giving the impression that the gas has been dissipated; (3) the amount in the air may rise so slowly that the olfactory mucous membrane is not stimulated. The danger of coal-gas poisoning occurs in connexion with leaky taps, pipes, and water seals, &c. The amount of CO is increased if to ordinary retort coal gas "water" gas is added. This water gas is manufactured by passing steam through red-hot coke, the products being principally hydrogen and CO. The addition of water gas to coal gas is quite common. The danger of poisoning from the CO contained in coal gas is enhanced by the presence of irrespirable gases, the amount of these latter varying from 60 per cent. to 70 per cent. The explanation is that when a mixture of air and carbon monoxide gas is breathed there is competition between the oxygen of the air and the carbon monoxide for the hæmoglobin in the corpuscles. If the oxygen tension is decreased relatively more CO is able to effect combination. The presence of irrespirable gas by lowering the oxygen tension facilitates the entry of the carbon monoxide and thus increases the risk of poisoning. Carbon dioxide gas (CO_2) is also present in coal gas; values 2·5 and 3·5 per cent. are common. In men and animals, carbon dioxide, which stimulates the respiratory centre, may increase ventilation and thus facilitate the access of carbon monoxide to the blood passing through the lungs. This factor is probably of small importance since the amount of CO_2 in ordinary coal gas is small, but it becomes of increasing importance in gaseous mixtures, to which reference will be made, where much higher percentages of CO_2 are met with. Because of the irrespirable gases and the CO_2 in coal gas its toxicity is roughly double that which its CO content alone would suggest.

5. *Carbon Monoxide in Producer Gases.*

Various other combustible gases are made and used in commerce; the analyses of some of them are given in Table III.

TABLE III.[4]

Type of gas.	Percentage of certain gases by volume.				
	H_2	CH_4	CO	CO_2	N_2
"Blue" water gas ..	52·0	1·0	38·0	4·5	4·5
Carburetted water gas ..	35·0	13·0	32·0	4·5	5·5
Mond gas	27·5	2·0	11·0	16·5	43·0
Dowson gas	20·0	1·0	24·0	6·0	49·0
Suction ,, ...	16·0	—	34·0	3·0	47·0
,, ,, ...	16·0	2·0	22·0	6·0	54·0
Blast furnace gas ..	3·0	1·0	26·0	9·0	58·0
Coke oven gas	53·0	35·0	6·0	2·0	2·0

The danger of these gases is largely due to the carbon monoxide which they contain, but this, as explained above in Section 4, is increased by the presence of irrespirable gas and of CO_2. In addition, some of these gases are without odour.

6. *Carbon Monoxide in the Products of Incomplete Combustion.*

Whenever charcoal hydrocarbons or other chemical substances containing carbon are burned with insufficient air carbon monoxide is largely to be found in the gaseous products of combustion. Sometimes the air is restricted intentionally in order that the gases produced may reduce—e.g., some metal ore present. In other cases the restriction is not intentional but is unavoidable, as, for example, in an anthracite stove. In others, again, it is accidental—for example, a gas stove with a closed air inlet.

This classification is not always very easy to apply, so that I have grouped these cases together as follows: Carbon monoxide may be found in the gaseous products from (*a*) engines burning coal, coke, anthracite, wood, alcohol, paraffin, petrol, benzole, coal gas, producer gas, petrol gas, &c.; (*b*) stoves, furnaces, or flames burning any of the above. The presence of CO in these products is naturally not dangerous of itself, but only when as the result of certain circumstances the products are respired by men or animals. For example, an anthracite stove may be correctly installed and used. As the result of a cowl jamming the wind causes a draught down the chimney. In consequence the products of combustion fill the house. Gas cookers (kitchen ranges) are frequently fitted without any direct ventilation.

Carbon monoxide may enter the room (*a*) as a result of faulty burner design or adjustment; (*b*) accidental stoppage of orifices or displacement of parts; (*c*) accidental firing at the gas inlet (firing back); (*d*) a cold surface in contact with the flame may cause it to go out before complete combustion has been obtained.

7. *Carbon Monoxide in other Gases.*

These form a miscellaneous group which may be classified as follows: (*a*) Natural gases—e.g., volcanoes. (*b*) Incomplete combustion of carbon, other than those mentioned in paragraph 6—e.g., underground combustion of wood or coal, or tobacco smoke, dangerous presumably only when inhaled. (*c*) The gases produced by explosives. (*d*) Cases where carbon compounds are being dealt with by catalysts or enzymes. The intestinal gases of herbivora are stated to contain carbon monoxide. I have found CO in sheep's blood obtained from the butcher.

8. *Carbon Monoxide in Petrol Motor Exhaust.*

As might be expected the amount of carbon monoxide in the exhaust gases of motor-cars varies greatly. It varies with the completion of the combustion and also with the ratio of fuel to air. So long as there is free oxygen in the exhaust the quantity of carbon monoxide is small. But before the oxygen has completely disappeared from the exhaust gas carbon monoxide is present in noticeable content, and it is found in increasing amounts as the mixture is made richer. Table IV. shows not only the way that decrease of oxygen is accompanied by increase of carbon monoxide, but shows also the way that the power developed by the engine varies.

TABLE IV.[5]

Ratio air to fuel.	Power developed.	O_2 per cent.	CO per cent.
23·9 to 1	9·8	7·6	0·0
20·1 to 1	15·5	4·8	0·0
18·1 to 1	18·1	3·8	0·4
17·2 to 1	18·5	2·1	0·1
15·5 to 1	19·7	0·6	0·4
14·0 to 1	20·0	0·4	2·4
13·5 to 1	19·9	0·2	4·0
12·5 to 1	19·8	0·1	6·3
11·5 to 1	19·8	0·2	8·1
10·9 to 1	19·9	0·4	10·6
9·9 to 1	20·0	0·6	12·1
8·2 to 1	15·1	0·0	15·3

Inspection of the table will show that the power developed by the engine rises rapidly as the mixture

is made stronger from 23·9 to 1 of fuel to 18·1 of air to 1 of fuel. From this point onwards the power of the engine rises slowly to a maximum, forms a slight plateau, but stays for practical purposes at the same value until the mixture reaches the ratio of 9·9 air to 1 of fuel. A stronger mixture than this causes a sharp fall in the power. The oxygen in the exhaust falls fairly steadily from 7·6 per cent. to 0 per cent., whereas the carbon monoxide steadily rises from 0 per cent. to 15·3 per cent., and the important point should be noted that unless there is some carbon monoxide in the exhaust the full power of the engine will not be developed. And not until there is 15·3 per cent. carbon monoxide in the exhaust will the power of the engine fall off noticeably. Now it is an unfortunate fact that a carburettor with given sized jet and air passages will produce a weaker mixture at slow speeds than at fast, and, what is more important, a weaker mixture when the engine is cold than when it is hot. The cause of this is that as air is warmed it expands, and so a smaller weight of hot air will enter the engine than would be the case if the air were cold. On the other hand, a greater weight of warm petrol will enter the engine than would be the case if the petrol were cold, because petrol decreases in viscosity as it becomes hotter, and so a greater weight flows through the jet in a given time.

The mixture, therefore, becomes richer as it becomes hotter, since the petrol increases but the air decreases. If, then, the carburettor is so adjusted that it gives a mixture which will fire well and develop nearly full power when the engine is cold, it is certain to give an unnecessarily rich mixture when the engine is hot. It is for this reason that the average motor-car in adjustment is found to produce an exhaust containing about 4 to 10 per cent. carbon monoxide. There is also present in the exhaust irrespirable gas and carbon dioxide gas, and therefore the three factors discussed in the case of coal gas are all present. The poisonous effects of exhaust gas are therefore greater than its carbon monoxide content alone would suggest. In addition there may be unburned petrol vapour. The symptoms of this are not very unlike those of carbon monoxide poisoning—dullness, dizziness, sickness, and weakness of bowels. The principal points of difference are, there is no flushing and no increased rate of heart and respiration as in the initial stages of CO poisoning. In addition, there may also be present nowadays in the exhaust compounds of lead as the result of lead tetra-ethyl in the exhaust.

It would be digressing from my subject to give full details, but these points may be mentioned: The symptoms of lead tetra-ethyl poisoning[6] are usually insomnia, headache, sickness, pallor, loss of weight, itching of skin, muscular weakness, and tremor. Unlike ordinary lead poisoning there is no lead line round the gums and no abdominal pain. But like ordinary lead poisoning lead is found in both fæces and urine; the latter is very acid. With adequate precautions there is no evidence that harm will result to the user of ethyl petrol.[7] Men engaged in its manufacture or blending run much greater risk. Present-day petrol engines will probably not be found to give improved results with its use. Engines to be designed in the future with high compression ratios may be expected to give somewhat greater efficiency. The risk of motor-car exhaust poisoning in the open country is negligible. Poisoning may occur in tunnels under rivers, traffic blocks, closed garages, and bench tests in workshops. Leakage of exhaust gases and gas from the crank chamber into saloon cars is a likely cause of poisoning, as also is the case of exhaust heated radiators and foot warmers.

9. *The Tests for Carbon Monoxide.*

Carbon monoxide may in a suspected case be tested for either in the air or in the blood of men or animals which have been exposed to that air. The tests for carbon monoxide in air are: (1) mice or small birds; (2) combustion and estimation by heat generation [9]; (3) combustion and estimation as carbon dioxide (Haldane's method); (4) iodine pentoxide; (5) ammoniacal chloropalladate [10]; (6) ammoniacal silver nitrate; (7) absorb by blood and estimate the CO in it.

For the quantitative estimation of carbon monoxide in blood the following methods have been used: (8) the carmine method (Haldane); (9) the tannic pyrogallic acid method [11]; (10) the reversion spectroscope [12]; (11) the photographic method.[13]

I have no personal knowledge of method (9). It is said to estimate carbon monoxide in blood with an accuracy of 5 per cent. The carmine method has the disadvantage of requiring good daylight for the titration, because daylight has a photo-chemical effect causing carbon monoxide to leave blood. Method (10) in practised hands is accurate to 5 per cent., method (11) to 2 per cent. With special technique these values may be halved. The corresponding values for CO in air would be 0·008 and 0·003 per cent. Method (10) has the advantage that the quantity of blood required for a test is small; 0·1 c.cm. is ample.

10. *Prevention and Treatment of Acute CO Poisoning.*

Prevention consists: (1) In preventing access of the carbon monoxide-containing mixture to the lungs of men and animals, by the provision of suitable flues, pipes, taps, meters, &c. (2) In the provision of suitable tests so that the adequacy of such flues, pipes, &c., can be periodically tested. (3) In the provision of suitable masks [8] so that if men have to enter a poisonous atmosphere they may be adequately protected. (4) By the provision of suitable remedies so that if any of the above precautions fail life may not be lost. The remedies consist of oxygen in cylinders or better oxygen 50 per cent. carbon dioxide in cylinders and a mask or funnel for administering same. In addition hot-water bottles should be ready to hand since warmth has been shown to be an important factor in saving life from carbon monoxide poisoning. Artificial respiration may be necessary. Stimulation of the respiratory centre by injections of potassium cyanide has yet to stand the test of time. Blood transfusions may be resorted to.

11. *Chronic Carbon Monoxide Poisoning.*

Cases of acute CO poisoning are fairly clear as a rule Chronic cases are not so readily diagnosed. The amount of CO in the blood at any time may be small and in the absence of special apparatus may not be detectable. As with acute CO poisoning I think we are justified in dividing cases into two classes—those in which compensation takes place and those in which it does not. The former compensate for the CO present in the blood by correspondingly increasing the oxygen-carrying power of the blood. This may be done by increasing the number of corpuscles per cubic millimetre of blood or increasing the hæmoglobin (colour-index) per corpuscle. The change would not be obviously different from that which follows living at a high altitude, where the oxygen tension in the air is below the normal value.

In the uncompensated cases, on the other hand, the reduction in the oxygen-carrying power of the blood seems to act almost as "the last straw." Numerous and varied are the conditions which are stated to follow the chronic poisoning: Pneumonia, tubercle, anæmia, &c. It is particularly necessary therefore that adequate diagnostic methods should be available. Birds and other small mammals are useless for testing for the amount of CO in air which will produce chronic poisoning, since tests show that their blood takes up less CO at a given per cent. CO in air than the blood of man. Tests of much greater precision are required. The symptoms of uncompensated CO poisoning may be shortness of breath, particularly on exertion, headache, pallor, weakness, sleeplessness, coldness in the extremities, and depression. The treatment is, of course, to find out the cause and to stop it, and to give the patient fresh air, tonics, and good food, and plenty of outdoor exercise.

12. *The Medico-Legal Aspect.*

Acute CO Poisoning.—In acute carbon monoxide poisoning the symptoms and history of the occurrence must usually make a decision fairly easy. If in addition there is the evidence of an expert as to the amount of CO in the patient or in the air he was breathing no questions would appear possible. But if this evidence is lacking and the patient is only examined some time after the incident then difficulties may arise. Even after the lapse of many hours, however, a delicate test may enable CO to be found in the blood since the rate of excretion is slow particularly as the percentage still in the blood approaches zero. Thus after 30 per cent. CO in the blood some may usually be detected eight to ten hours later. If the amount is measured and the numbers of hours since exposure is known the probable amount present at the maximum may be roughly inferred.

Chronic CO Poisoning.—Here the symptoms are more vague, the history as a rule less certain. But, as in acute cases, reliance should be placed on finding CO in the blood. If none is found it does not exclude the possibility from a medical standpoint, for the circumstances may be such that the amount of CO in the blood fluctuates, and at the time of the test the amount may be below the threshold value for the test that is used. In such a case further tests at other times of the day should be made with the man engaged in his ordinary routine, and tests of the air should be made at his home and his business.

MEDICINE AND THE LAW.

Income-tax Subtleties.

HIGH taxation is notoriously a reason for the diminition of voluntary gifts to charitable foundations, and the committees of hospitals and similar institutions are keenly interested in any possible concession. Some years ago the University College of South Wales and Monmouthshire appealed for a sum of £250,000 for general development and for the particular object of its physics and chemistry laboratories. There was reason to believe that, if donors made contributions out of taxed income and spread them over a period of seven years, the College would not only benefit by the contributions themselves, but would also be able to reclaim the amount of the tax already paid. Certain generous donors then entered into formal covenants undertaking to pay the College out of their taxed income a specific sum in quarterly instalments during the next seven years. These instalments they duly paid, but the Inland Revenue authorities were unable to fall in with the plan. One must distinguish, it seems, two different ways of expressing the covenant in benefactions of this character. One way is to promise to pay a specific annual sum out of taxed income yearly for seven years; in this case the Inland Revenue appears to be willing to hand back the tax if it is claimed by the institution which receives the benefaction. The other way (the form adopted in the University College instance) is to promise to pay a capital sum spread over seven years; in this case the Inland Revenue refuses the refund. Having framed their promises in the form unacceptable to the Inland Revenue authorities, the benefactors went to the Court of Chancery and asked that their promises might be rectified. A benefactor, whose total gift was to be £28,000, requested that the following words should be struck out of his covenant "during seven years . . . I will pay from my general fund of taxed income, in quarterly instalments, the sum of £28,000 net," and that the following words should be substituted "for seven years . . . I will pay from my general fund of untaxed income on April 1st, July 1st, Oct. 1st, and Jan. 1st in each year the sum of £1000 net." The University College of South Wales was formerly made a defendant in the action but, naturally, did not object, and therefore allowed judgment to be entered in default of any defence. Mr. Justice Astbury made the orders for rectification as requested, but confessed he could see very little difference between promising to pay £7000 in annual instalments and promising to pay seven annual instalments of £1000 each. The plaintiffs had invited the chief inspector of taxes to intervene in the proceedings, but the Board of Inland Revenue was not to be drawn. It refused to intervene and it declined to be taken to be supporting the application. Thus there seems no certainty yet that the University College has made sure of its claim for refund of tax. It is hard enough to master the law of income-tax; even when there is no doubt of the law, there remains a doubt of what policy the Inland Revenue authorities will adopt. Though it is not their function to be prodigal with money which has found its way into the Exchequer, it would be kind of them to make clear the exact circumstances in which tax will or will not be refunded.

Dairyman Imprisoned.

An Ilford dairyman, who had supplied milk diluted with 5 per cent. of added water, was sentenced last week at the Stratford Police Court to a month's imprisonment with hard labour. A fine is usually considered a sufficient penalty upon a retailer who offends against the Food and Drugs Acts, but this defendant had previously been fined six times for offences in connexion with the supply of milk in the past 12 years. The chairman of the Bench described him as a pest who continually defied the law and robbed the public. There was a second charge, for obstructing two inspectors of the Essex County Council; in respect of this he was sentenced to £25 with the alternative of a month's imprisonment. It would be to the public advantage if the law allowed a court to make an order debarring such habitual offenders from taking any further part in the sale of food.

LISTER INSTITUTE OF PREVENTIVE MEDICINE.

ANNUAL GENERAL MEETING.

AT the annual general meeting held on May 23rd a tribute was paid to the memory of Lord Iveagh whose endowment of the Institute, in 1898, enabled the objects for which it was founded to be pursued on a much larger scale. The Governing Body records its appreciation of the continued coöperation it has enjoyed with the Medical Research Council, the Department for Scientific and Industrial Research and the British Empire Cancer Campaign. The department of Biochemistry has been entrusted by the Medical Research Council with a lengthy inquiry into the vitamin-content of Empire products and the effect of preservation and storage thereon. Dr. S. S. Zilva is in charge of the investigation, the cost being defrayed by a grant from the Empire Marketing Board.

Department of Bacteriology.—During the past year Prof. J. C. G. Ledingham has elaborated a method

of propagating vaccine virus in the dermis of the rabbit. Following on his discovery three years ago, that small-pox material taken direct from man was capable of producing a marked response in the dermis of the rabbit, he has attempted to pass the small-pox virus from rabbit to rabbit with only moderate success. The passed material from the dermis seems to lose its virulence rather rapidly and the cause of this requires further investigation. As a laboratory test for small-pox the intradermal inoculation of the rabbit with human material is recommended. Dr. C. H. Eagles and Dr. D. McClean are using the dermal vaccine as seed in their experiments on the cultivation of the virus in vitro in association with chicken embryo. Studies on bacterial variation and the antigenic structure of bacteria have been undertaken by Dr. J. A. Arkwright. Working on *B. typhosus* he has examined the conditions of agglutination by serum and acids, concluding that substances agglutinable by serum and by acid are probably identical. An investigation by Dr. H. Schütze of 18 strains of *B. pseudotuberculosis rodentium* and related organisms has resulted in their classification into three types ; one of the pseudotuberculosis groups has a serological affinity with certain Salmonella strains.

The action of the toxin of *B. welchii* on red cells in vitro has been studied by Dr. Orr and Dr. Campbell in view of the claim that *B. welchii* plays some part in the ætiology of pernicious anæmia and that a form of chronic anæmia can be produced in animals by inoculation with cultures of this organism. They have exposed emulsions of red cells to the action of filtered broth cultures of *B. welchii*, these filtrates containing a hæmolysin of variable strength. It was found that the red cells passed through definite changes, microcytes appearing first, followed by macrocytes, and these again by a stage in which the majority of the remaining cells have resumed their normal diameters. This change in size was not met with when other hæmotoxins—e.g., from *V. septique*, *B. tetani*, streptococci, and straphylococci, &c.—were used. By using blood which had been reduced hæmolysis could be speeded up considerably ; and the change in size, moreover, proceeded at a more rapid rate than when ordinary oxygenated blood was used. The interpretation of these observations and their possible relation to the blood picture of pernicious anæmia are under consideration.

Among the many researches in progress are those concerned with the vitamins. Dr. Zilva has worked on the relation of the reducing capacity exhibited by substances rich in vitamin C to their antiscorbutic activity. It transpired that in spite of the close association, the reducing agency and the active principle are not identical, but that the former contributes to the stability of the latter. It was found that the reducing agency is not the only stabilising principle associated with antiscorbutic solutions. An inquiry on the variation of the antiscorbutic factor in apples has been started by Dr. Zilva and Mr. Hoyle. Apples grown and stored under carefully controlled conditions and apples of known history from the various Dominions are being investigated. The results so far obtained make it clear that the vitamin content of apples is by no means uniform and that it is controlled by various physiological factors. Dr. Smedley-MacLean has continued her investigation of the nature of the unsaponifiable matter of yeast fat, now the main source of ergosterol (provitamin D), and has isolated from it a second sterol, to which the name of zymosterol has been given. Zymosterol is distinguished from ergosterol by its greater solubility in organic solvents, its dextro-rotation, and the absence of selective absorption in the ultra-violet region. The biological properties of the irradiated sterol are being tested in conjunction with Miss E. M. Hume and Miss Henderson Smith.

Department of Experimental Pathology.—The testicular and prostatic hormones have been studied by Dr. V. Korenchevsky, in coöperation with Miss M. Schultess-Young, also the effect of ovarian extract of parathyroid extract, and of pituitary gland on nitrogen metabolism. The two active constituents of water-soluble B vitamin have been further examined by Dr. Harriette Chick and Miss H. M. Roscoe. They suggest that these should be called, provisionally, vitamin B_1, the antineuritic, more heat-labile, constituent and vitamin B_2, the so-called "anti-pellagra," more heat-stable constituent. When young rats receive a diet complete in all respects, but devoid of vitamin B_1, they survive only 3–4 weeks and die with or without symptoms of paralysis. If, on the other hand, the diet is deficient only in vitamin B_2, life may be prolonged for 2–3 months or longer, but there is no significant increase in weight, and growth is at once restored if vitamin B_2 is given. A concentrated preparation of the antineuritic vitamin B_1 can be prepared, which is devoid of vitamin B_2. Attempts are now being made to isolate the other vitamin and to investigate its distribution in different whole cereals and their constituent parts. The existing knowledge regarding the distribution of what was called vitamin B has been compiled chiefly on the results of experiments upon the prevention and cure of polyneuritis in pigeons and, therefore, has reference only to distribution of vitamin B_1. The curious phenomena named "Refection," the spontaneous occurrence of the capacity to thrive on diets deprived of B vitamins, which has been studied recently by L. S. Fridericia and his colleagues in Copenhagen, was also discovered independently at the Institute. The most reasonable explanation, and the one adopted by Fridericia, is that the alimentary tract of the animal becomes infected with some yeast or other organism and thus the materials are produced which are needed to correct these different defective diets. The titration respectively of vitamin A and of vitamin D has been the subject of investigation by Miss Hume working with Miss Henderson Smith, and Miss K. M. Soames working with Miss J. L. Leigh-Clare. The assessment of the proportion of the total energy absorbed when sunshine falls upon the skin has engaged the attention of Sir Charles Martin for some considerable time. As the amount absorbed cannot be directly measured, it was hoped to arrive at it by determining what was not absorbed—i.e., the amount irregularly reflected. Some interesting comparative data were obtained, and certain difficulties having recently been surmounted, it is hoped that quantitative measurements will soon be obtainable.

Dr. T. Lumsden, with the assistance of Miss A. C. Kohn-Speyer, continued his investigations into the feasibility of producing a vaccine effective against malignant tumours.

The Department of Protozoology has made further experiments upon *Bodo caudatus* exposed to the influence of acriflavine, and Dr. H. M. Woodcock has continued his work on the encephalitis of rabbits. Rabbits have been successfully inoculated intracerebrally witn an emulsion of an infected kidney of a dying rabbit.

Department for the Study and Preparation of Antitoxic Sera.—Research in this department has been concerned with the preparation of plague toxins and of anti-plague serum, the use of formalised antigens in the production of therapeutic sera, and the experimental production of pneumococcal endocarditis, and of arteriosclerosis in rabbits.

Investigations on Foot and Mouth Disease, for the Research Committee of the Ministry of Agriculture, have been continued at the Institute during the year in the special laboratory and animal house set apart for the purpose, under the supervision of Dr. J. A. Arkwright. The lines of investigation pursued have included an inquiry into the cause of the restriction of the lesions to the feet and mouth ; the fate of the virus in the bodies of convalescing animals ; the survival of the virus upon various materials, and under a variety of conditions ; the susceptibility of wild animals to infection, and a general study of

artificially induced immunity to foot and mouth disease. The Third Progress Report of the Foot and Mouth Disease Research Committee will be published shortly.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Conflicts in the Medical Profession.

THE increasingly difficult position of physicians in this country has divided the profession into three distinct groups: (1) doctors employed in full or in part by the *Krankenkassa*, or sick-clubs, numbering about 1200; (2) independent doctors with no fixed salaries, of whom there are about the same number; and (3) hospital staff doctors, university lecturers, and medical officers of health, some 2000 in all. The last group sometimes throws its lot in with the first and sometimes with the second, according to personal interests. The clash of interests between the three groups was recently manifest when the Government, or rather the political parties, attempted to win the votes of certain sections of the community by organising a new sick-club for bank employees and certain business and factory clerks. The formation of such a club would result in a large and by no means poverty-stricken section of the community being taken out of the hands of the private practitioner. The organisation of Vienna doctors refused to accept the proposal, and as its president, together with a fair proportion of representatives of the sick-club doctors, favoured the Government's plan, he was forced to resign. After a very heated election campaign the representative of the independent doctors, Dr. Weinländer, was elected president by a small majority. Thereupon the other group threatened to separate from the organisation, and the danger of a split in the profession seemed imminent. The conservative elements in both groups were anxious to bring about a reconciliation, and a few days ago we learned that some sort of an understanding had been reached which will enable all medical men to partake of the opportunities afforded by the formation of a new big sick-club. Only a few appointments with fixed salaries will be made for members living in outlying districts, all other members being allowed to choose their physician and specialist from a panel of doctors. Payment will be made at a fixed scale according to work done—i.e., for each consultation or call. This means that the practitioner will have to work for lower fees than those paid by private patients, but these are gradually disappearing. He does not lose his private patients entirely as they may come to him as panel patients. The sick-club doctors on their side have consented not to oppose the attempt which is being made to remove from membership of the sick-clubs those persons whose income is above £25 to £30 a month. A certain section of wage-earners should thus be left to the private practitioner. The profession is also trying to bring this condition concerning income into force in the other sick-clubs, especially amongst railway, municipal, and state officials. Many of these have salaries of £50 to £80 a month. Yet they are all compulsory members of the sick-clubs though this income is considered large in this country, being greater than that of most medical practitioners.

Voronoff's Operation.

At a recent meeting of the Vienna Society of Physicians Dr. Schleyer showed two patients who six months previously had undergone Voronoff's operation, which consists of implantation of part of the testis of a monkey into the testis of a man. The patients were 70 and 56 years of age respectively, and their condition before operation was typical of senility, showing loss of mental and physical strength, with forgetfulness, fatigue, impotence, and loss of libido. No change was noticeable for five weeks after the operation, but the older patient then stated that he was beginning to feel much better, and after nine weeks he again had erections; the younger also felt stronger and was more active. Both men are satisfied and look strong and healthy. In the discussion which followed Dr. Schönbauer, from the Eiselsberg Clinic, reported on four Voronoff operations, two of which had had good results, and two of which had been failures. Experiments have been made in the clinic on the transplantation of testicles from one monkey to another, and it was shown that the transplanted gland was always destroyed, microscopical examination showing that destruction took place within three months. Dr. Bachrach says that he has got the same results as Voronoff claims for his method by implanting testicular tissue into the muscles of the abdominal wall. Prof. Bauer, who at first was sceptical about the results of the operation, had to admit that even excluding auto-suggestion the improvement of somatic conditions is undeniable. He thinks that the implantation of young glandular material into testes suffering from regressive changes causes a distinct renewal of their function. Suggestion must be excluded, for the favourable results do not appear till some weeks after the operation. Prof. E. Schwarz is not in favour of the word "rejuvenation," since he believes that the normal physiological process of senility cannot be prevented by our interference. Transplantation—an operation which can be repeated several times—simply results in a temporary renewal of the production of testicular hormone, and this disappears with increasingly short intervals after each transplantation. Death cannot be averted. The effect, as Voronoff himself has stated, lasts at most from two to four years, but even this added period of well-being is important to the aged, as Dr. Schleyer remarked in summing up the discussion.

Statistics of Practitioners in Vienna.

As a result of the registration of medical men now being carried out by the Vienna Board of Health, some interesting facts have come to light. The youngest practitioner (apart from hospital doctors) is 23½ years of age, and the oldest 87. The majority enter the ranks of wage-earners at the age of 29½ (40 per cent.), whilst only 12 per cent. settle down after the age of 36. More than 70 per cent. of all practitioners are between 40 and 65 years, and 9 per cent. of the total are women. There are 3·5 doctors per 1000 inhabitants, and 3·8 women doctors per 10,000 female inhabitants. Whilst only 11 per cent. of the population of Vienna are Jews, they form over 30 per cent. of the profession. Only Austrian subjects are practising here, but over 20 per cent. are foreign born—i.e., were born in places now situated outside the Austrian Republic. More than 22 per cent. of the total are specialists, and 10 per cent. are dental surgeons. About 2000 medical men (apart from the dental surgeons) have a telephone, and no doctor is allowed to practise in two separate places. Panel doctors, however, can use their own consulting-room for private patients if the *Krankenkassa* provides them with another one elsewhere for their panel patients.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

B.C.G. Vaccine.

THE extent to which the daily press in Paris has commented on the recent discussion at the Academy of Medicine on B.C.G. vaccine is a sign of the interest taken in this matter by the man-in-the-street. The fact that 81,600 infants have been inoculated with the vaccine in France alone, between July 1st, 1924, and May 1st, 1928, shows how extensive has been its employment, and in as many as 75,000 cases it has been given to infants in non-tuberculous surroundings. This is a point of the greatest importance; no one apparently, had any cogent objections to raise to the use of B.C.G. in infants born into tuberculous surroundings. The immediate and ultimate effects of B.C.G. inoculation might be rather unpleasant

but they were obviously the lesser of two evils when the chances of a tuberculous infection were great. But—and this was the point on which Prof. Lignières insisted repeatedly during the discussion—is it at the present stage justifiable to inoculate healthy infants in healthy surroundings with a live virus about whose ultimate fate in the body insufficient information is available? In support of his hesitation on this score, he drew attention to the frequency with which Dr. Tzekhnovitzer, of Kharkoff, found rabbits, inoculated with B.C.G., to die of unknown causes. He implied that the B.C.G. might at any rate have been a contributory factor in some, at least, of these deaths. With regard to Calmette's statistics, Lignières suggested that if these are to be beyond reproach the best procedure would be to inoculate every other infant and animal concerned. Calmette's defence consisted of stressing the hypothetical, problematical, theoretical, suppositious, quasi-prophetic character of the criticism advanced, and he concluded with the statement that he had not yet been faced by a single observation of a case of an infant, born or brought up in healthy surroundings, inoculated with B.C.G., and dying of a tuberculous infection caused by B.C.G.

The Association for Developing Medical Relations is organising a number of courses to be given in English at Paris. The subjects include operative surgery, cardiology, pediatrics, and ophthalmology, and further announcements will be forthcoming later.

A course in dermatology and venereology will be held at the clinic for cutaneous and syphilitic diseases at Strasbourg from Sept. 17th to Nov. 3rd, under the direction of Prof. L. M. Pautrier. Those who attend will be given the opportunity of personally applying the various methods of treatment, and will have free access to the clinic outside the hours of the lectures. Applications should be sent to Prof. Pautrier, 2, Quai St. Nicolas, Strasbourg, who offers to send particulars of accommodation in the city.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Tularæmia: Human Autopsy.

AN autopsy made in St. Mary's Hospital, Duluth, Minnesota, on a man who died 16 days from the known inoculation of the disease, shows that the pathology of tularæmia in man resembles very closely that already demonstrated in animals. The infection in his case was virulent. Two days from inoculation the patient was compelled to take to his bed and the disease progressed through cyanosis and stupor to death, which occurred before the positive serodiagnosis for tularæmia had been returned from the state laboratory. The inoculation had taken place in the middle finger of the left hand from the ulcer in which a purulent exudate was expressed at autopsy. The epitrochlear gland was considerably enlarged, and there was enlargement of a few left axillary glands. Definite nodules were found scattered over the pleura of each lung, in the lung substance, in the liver, kidneys, and spleen (particularly concentrated beneath the capsule). There was broncho-pneumonia in both lungs. In the intestines Peyer's patches of solitary follicles were found swollen and congested. Microscopically the nodules of tularæmia closely resemble miliary tubercles. The nodule, however, grows much more rapidly than in tuberculosis and attains a much greater size. It tends to depress the surface of the affected organ rather than to elevate it, and is slightly irregular. Giant cells, though they have been found in previous cases of tularæmia, were not present in this case, which terminated more rapidly than any previous case that has come to autopsy.

Destruction of Mouse Sarcoma by High-frequency Currents.

Remarkable success in the destruction of a transplantable sarcoma in mice by high-frequency electrical oscillations is reported by Dr. J. W. Schereschewsky,[1] of Harvard University and the Public Health Service. The frequencies that have been most successful have been between 68,000,000 and 66,000,000 cycles per second. The effect of treatment is immediate and pronounced, and a small tumour of 485 mm. may become almost impalpable. A reaction follows in 24 hours with œdema of the treated area. In favourable cases, when the œdema had subsided, the remains of the tumour grew smaller and smaller until they disappeared. When the current used is 300 milliampères or less the skin disturbance is slight. When more powerful currents are necessary some superficial necrosis of the skin results. The percentage of recovery of 403 mice was 25 per cent., the remainder dying, mostly of intercurrent infection, before the death of the last control mouse. In the controls no spontaneous regression was observed. Only 5·5 per cent. of the treated mice actually died from tumour. Some success also has been achieved with the Rous fowl sarcoma, and Dr. Schereschewsky thinks that a different frequency may be more successful in this latter tumour. (A frequency of 135,000,000 proved to be useless in the mouse sarcoma.)

As to how the result is achieved little is known. The thermal effect of these very high frequencies, unlike that of medical diathermy, is slight. Sections of the tumour after treatment were examined by Dr. S. B. Wolbach, who reported as follows:—

> "In general, the immediate effects of the agency . . . is necrosis to the tumour cells and accompanying vascular and connective tissue structures. The general picture produced is that of so-called coagulation necrosis and the most familiar corresponding picture that I know of is in completely infarcted tissues. A very striking phenomenon, however, as brought out in the slides, is the extraordinarily rapid disappearance of the necrotic tumour. I am quite unfamiliar with anything corresponding to it. In the few microscopic preparations submitted one gets the impression that there has been very rapid solution, possibly solution by autolysis (?) of the cells including the nuclei."

The most serious limitation to the method is that, so far, it has been possible to apply it only to subcutaneous tumours.

The Detroit Department of Health has recently made an interesting survey in an attempt to discover what are the factors which are preventing the public from making use of toxin-antitoxin. A sample of 100 cases of diphtheria was chosen and in each case the parents were asked to state the reasons why their children had not been protected. In nearly one-half the cases (45) the reason was given as plain procrastination. This makes evident the duty of the family physician to urge the importance of this measure and the dangers of delay. In 14 cases the parents had not heard of toxin-antitoxin and only in nine cases did the parents urge that they had no faith in this method of prevention. In nine cases fear of pain had been the hindrance.

The Parker Bill for the coördination of the public health activities of the federal government was passed last month by the House of Representatives. Besides facilitating the exchange of personnel between different bureaux of the health service the Bill will establish a corps of nurses and a national advisory health council and will increase the scope of the hygienic laboratory. It has still to receive the approval of the Senate and the signature of the President.

The fifty-seventh annual meeting of the American Public Health Association will be held in Chicago from Oct. 15th to 19th. The American Child Health Association and the American Social Hygiene Association will meet with this organisation

"Audi alteram partem."

HIDEYO NOGUCHI.

To the Editor of THE LANCET.

SIR,—I wish to add a tribute to that paid in your columns last week to the memory of Dr. Hideyo Noguchi, whose untimely death from yellow fever at Accra on May 21st has deprived the world of one of the most distinguished scientists of our time. It is all the more regrettable as the investigation into yellow fever had but a short time previously claimed the life of Prof. Adrian Stokes, and science can ill afford such irreparable loss.

My first introduction to Noguchi was at the Rockefeller Institute in New York in 1922, within a few days of my arrival. There was a tap on the door of my room and in came Noguchi. He introduced himself, inquired about my welfare, and asked if he could be of any assistance. I was very impressed that this great man should seek me out and offer his friendship, but such was characteristic of Noguchi. I was a frequent visitor to his laboratory. He was never too busy to show me his technique, discuss problems, or demonstrate his experiments. Many a time, working late at night, I have passed Noguchi's room on leaving the Institute, and seeing the lights on, I entered. He would be busy, with the tables in his whole suite of rooms covered with innumerable cultures and specimens. A few words of welcome and a smile were always assured from him, and he seemed to welcome the break and would chat for some time. I never knew what time he stopped work. Noguchi was a hard worker, and when deep in a problem he took no cognisance of time. He did his microscopic work in the quiet of his own home, and there might find something which demanded laboratory work. He would set off at once to the Institute, arriving there any hour of the day or night in a taxi (he always travelled in taxis) and immediately engage himself in the new aspect of the work. Noguchi was a "mass" worker, and I think that was one of the secrets of his great success as a scientist. He persisted at his problems, carrying out numerous experiments, using great quantities of material; whereas the average laboratory worker trying out a new medium for some hitherto uncultivated organism might use, say, a dozen tubes, Noguchi would use hundreds. The organism might grow in only one of the tubes, but still it was there cultivated. Similarly, in his animal work it was not uncommon for him to use a hundred guinea-pigs for one experiment alone. Perhaps only one, or even two, reacted, but that was sufficient to establish a definite point. Other workers using less material would fail to get the single positive result. If genius is an infinite capacity for taking pains, then Noguchi was truly a genius. His many achievements are well known. The cultivation of spirochætes of several kinds, his researches into yellow fever, vaccine virus, the Wassermann reaction, Oroya fever, Rocky Mountain fever, trachoma, are some of the subjects in which he has enriched medical knowledge and made his name a household word amongst scientists.

He was rather a shy, retiring man, and did not mix freely with the rest of the workers, but preferred the quiet of his own laboratory. He did not seek the many honours he attained, but loved science for its own sake. A keen thinker, a hard worker, a great scientist, his loss will be mourned by those who knew him, not only as a scientist but as a friend.

I am, Sir, yours faithfully,

J. E. MCCARTNEY.

Southern Group Laboratory, Metropolitan Asylums Board, May 25th, 1928.

THE SOCIAL FACTOR IN ACUTE RHEUMATISM.

To the Editor of THE LANCET.

SIR,—The search for what may be called the social factor in the ætiology of acute rheumatism has not, so far, proved very fruitful; possibly, I think, because it seems to have been assumed that such a factor must have to do with external environment. The line of thought followed seems to be this: "Rheumatism attacks the poor and not the rich, it must, therefore, have something to do with poverty and its accompaniments or with the places in which the poor live." The soil, site, houses, and rooms where the rheumatic children live are therefore carefully studied and compared with the dwelling places of the non-rheumatic, but except for rather slender evidence implicating dampness, it will scarcely be said that any convincing environmental cause has been found. Dr. McSweeney's studies in Cardiff (THE LANCET, May 12th, 1928, p. 959), in particular, cast doubt on most of the suggestions hitherto made. The fact of the class-incidence of the disease remains, and its cause must be ascertainable.

Is it not possible to base an alternative argument on this admitted fact, running somewhat as follows? The children of the educated classes remain free from acute rheumatism whether they live on clay or gravel soil, in river valleys or on the hill tops, at home or in the boarding-houses of their public schools. This freedom is also shared by young people whose way of life is regulated by the educated—the inmates of orphanages instanced by Dr. R. Miller, and, most notably, the young soldiers in the war, when thousands of lads of 18 lived for months together in flooded trenches, dripping dug-outs, damp, dark cellars, and sodden camps with a very low incidence of rheumatism. In over three years of regimental and field ambulance work in France I cannot recall one typical case. "Trench fever," "trench nephritis," and "trench foot" we knew, but not "trench rheumatism." It hardly seemed possibly that after that vast experiment in the effects of damp and exposure the dampness theory could ever lift its head again. Thus the children of the educated and those under their protection and control have immunity; the disease falls, indisputably, on the less educated classes, but is said to spare, to some extent, the extremely poor.

If these facts are true, is it not at least possible that the differentiating social factor is to be found not in environment but in differing hygienic beliefs and habits? The rheumatic class, for example, clothes its children far more closely and warmly than the immune class; it is notably afraid of cold air, of "overheating"—i.e., strenuous exercise—and of underfeeding, while it views lightly the perils of carious teeth and infected tonsils. Is it not possible that the elusive social factor might be found by turning from environment to personal hygiene and investigating the amount of clothing worn, the quantity of daily food and of daily exercise enjoyed and the room temperatures maintained by typical families of the immune and the susceptible social classes? I am, Sir, yours faithfully,

Hampstead, May 24th, 1928. LINDSEY W. BATTEN.

MEDICAL WORK IN YUGOSLAVIA.

To the Editor of THE LANCET.

SIR,—The article on medical work in Yugoslavi in your issue of May 5th describes admirably th astonishing efficiency with which Serbia is tacklin questions of health. I have just returned from a wee in the Hygienski Savod at Skoplje. Malaria an other tropical diseases are its chief care, and it is a excellent example of an institute of public healt beautifully equipped and organised and functionin magnificently. The institute is the central station fo south Serbia, and work is carried on at some thirt subsidiary stations; medical attention is given i

the villages, anti-malaria work is directed, and there are even bath houses in many places where school children are washed compulsorily once a week—albeit that at first this sometimes needed the assistance of the gendarmarie. That such perfection is possible in the Balkans must be seen to be believed.

We were treated with the greatest possible kindness —in five languages— by the director, Dr. Rankov and his assistants, who were willing to give unlimited time and trouble in showing their work to foreign visitors. It is a remarkably good centre for studying some of the problems of malaria. Why, for instance, should blackwater fever be unknown in the Skoplje area, while here in Greek Macedonia as many as 36 cases were reported for last year in the hospital of Nea Moudania alone?

To anyone interested in research, or in the medical organisation of a "new" country, the institute at Skoplje is a veritable happy hunting ground.

I am, Sir, yours faithfully,

CICELY D. WILLIAMS, M.B. Oxf.

Society of Friends, Salonika, May 10th, 1928.

SOUND DEADENED ROOMS IN THE TREATMENT OF AURAL INFLAMMATIONS.

To the Editor of THE LANCET.

SIR,—When we give consideration to the damage of the internal ear from the influence of constant noise as seen in certain occupations where noise is concomitant, we realise that the ear has not received the protection that has been given to other organs by functional rest, especially during inflammation. The stomach is rested by a careful diet. The heart is helped by interdiction of the strain of exercise. The eye is kept shaded or in a dark room or its active function is minimised by atropine. An injured joint is mobilised. I might cite many examples where functional rest is considered a sine qua non of treatment in inflammation. No one has ever considered that the ear should receive the same care. Middle-ear inflammations are allowed to pass through their course without any thought that they are prejudiced by the environmental clamour. The sequels of chronicity and mastoid involvement are almost accepted as reluctable; we consider that we have done our best for conservation when we have opened the drum and used isotonic or antiseptic irrigations with appropriate therapy to the nasopharynx and the nose. A striking fact in the effect of noise on the internal ear is that only the tones that reach the internal ear through the oval window cause this degenerative change. Does it not seem reasonable that the functional activity of the middle ear may aggravate congestion and increase the potentiality of the aural sequelæ? We see so often aural inflammations which are beginning to show operative necessity resolve completely when hospitalised; how much more benefit would accrue to this partial rest by a more or less complete functional rest? The influence of silence on the course of laryngeal affections has been demonstrated and appreciated.

The ear stands alone of all the organs in that it gets no real rest during the 24 hours. The ossicles and drum membrane are receiving all sounds and transmitting them even in sleep. That we do not perceive all the sounds is due to the sleep of the higher centres resulting in a lack of attention. How much influence may over-function have in starting up the peculiar degeneration of the ear in otosclerosis? Why does the spongifying osteitis start around the place of greatest functional activity—the oval window? We may give due credit to the influence of endocrine dysfunction, to hereditary dyscrasy, to changes in calcium content or to other theories of this insidious, progressive, and incurable deafness, but we cannot explain why it begins at the foot plate of the stapes, the place of greatest functional activity of the ear. Senile deafness, appearing more early in life and before senescence of other special organs, is due to the over-stimulation of our modern environment. The clamant need, apparently, is rest. Physicists are experimenting in sound-proof rooms for the use of testing apparatuses to determine acoustic acuity.

No attempt has been made to gauge the benefit of functional rest in middle-ear inflammations; this has never been considered as a part of the treatment and has not been deemed necessary. Is it not possible that the continuous onslaught of sound would by conduction vibrations keep up or aggravate congestion? No differential trial has been made to determine the reaction of the inflamed ear under the ordinary environment and the reaction under functional rest. The majority of patients with middle-ear inflammations are ambulatory partly from custom, partly because it is easier for the patient to come to the doctor than it is for the doctor to carry around his apparatuses. Naturally the patient feels that his condition is not one that requires either local or somatic rest. There is a great deal of difference in the treatment of the ear and the meticulous care of the eye. Why?

It may be impracticable to suggest sound-proof rooms for aural inflammations, and of course it would necessitate a great change in hospitals to have sound-proof rooms. If that radical measure may not have a utilitarian appeal, at least the endeavour to lessen sound for the treatment of aural cases would be of decided benefit. I believe also that the onset of senile deafness would be slowed by occasional rest from noise—a rest that may be partially gained by wearing occlusive plugs occasionally. I make the suggestion, therefore, that sound-deadened rooms should be used for aural inflammations and that the majority of acute ear infections should not be allowed to be ambulatory, but should at least be semi-hospitalised in a quiet room. I venture to assert if hospitals would furnish sound-deadened rooms for the treatment of aural cases we might see fewer sequelæ which at present are a reproach to aural surgery and there would be instituted a distinct advance in preventive medicine.

I am, Sir, yours faithfully,

GEORGE B. MCAULIFFE.

26, West 87th-street, New York City, April 21st, 1928.

MEDICO-LEGAL RESEARCH.

To the Editor of THE LANCET.

SIR,—In your leading article on Status Lymphaticus (THE LANCET, May 26, p. 1078) you deplore the absence of a central institution in London where all medico-legal work could be concentrated in the hands of experienced pathologists to solve this and similar problems. One such problem is the constant occurrence of suicide attributed to ridiculously inadequate reasons. The oft-told story of "recent pains in the head and strangeness of manner" usually ends with a verdict of temporary insanity, with no attempt to discover by expert investigation the essential disease leading to such disaster. New light on the pathogenesis of such cases would help to prevent some of these calamities.

One would like to feel there is a likelihood of your important suggestion leading to some such central institute being organised.

I am, Sir, yours faithfully,

PATRICK WATSON-WILLIAMS.

Bristol, May 27th, 1928.

RHAZES AND AVICENNA.

To the Editor of THE LANCET.

SIR,—The eloquent and learned Linacre Lecture by Sir George Newman published in your issue of May 12th, cannot but have given great pleasure to all who heard it or have read it. I hope, however, he will allow me to offer an amplification of the sentence, in which he numbers Rhazes and Avicenna among the Arab physicians. It is true that they practised Arabian medicine, visited Bagdad, and wrote in Arabic, the scientific language of their day, but they were both Persians and were, as Sir George himself makes clear, original thinkers as well. Rhazes was

born, and lived, at Ray, and the Arabs therefore called him Ar-Razi, just as to-day we often add the name of his city, university, or hospital, to that of some particular worker. Now Ray was built, perhaps, 3,000 years ago, is one of the oldest of Persian cities, and its ruins are plain to see six miles from the modern capital, Tehran. Rhazes is the mediæval European form of Razi.

As to Avicenna, it is true that he was born near Bokhara, but his father was a Persian, and, at about the age of thirty, he himself moved into Persia and lived there for the rest of his life, chiefly at Ray and Hamadan, where he died and was buried (1037). His tomb is on the outskirts of the city, in a good state of preservation. A few years ago certain needed repairs were done by the local doctors and their friends. Need more be said of his fame than that he is quoted to-day by Persian physicians?

Persia may well claim Avicenna and Rhazes as two of her most illustrious men.

I am, Sir, yours faithfully,

London, May 23rd, 1928. A. R. NELIGAN, M.D.

RADIUM TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—In your issue of May 26th (p. 1101) appears the following report of a speech made by Dr. Vernon Davies in the House of Commons:—

"He (Dr. Davies) wanted to impress upon the committee and upon the country that the only safe thing for cancer was early and complete operation. Unfortunately it occasionally happened that they got cases which were late and inoperable, and then perhaps radium treatment might prolong the life of the patient, or perhaps give him a little more ease; but whatever they did they should not get into their heads the idea that radium would cure cancer; it could not do it at the present time. It was only a help, and he was afraid that the rather hopeful tone of the Minister of Health might create a wrong impression in the country and prevent some of those poor people from seeking medical advice in the early stages when something could be done."

This extraordinary misstatement is surely calculated to create a great deal of harm. It seems to be hard enough for many of our British surgeons to realise completely the present-day success of radium treatment, when properly applied to some of the carcinomatous diseases in certain situations where operative surgery is quite impossible, apart from many cases where there might be a choice between operation with removal of a large portion of tissue, and radium with its selective action, microscopically, on individual cells. Thousands of cases have been successfully treated in Great Britain, in certain centres where its action has been properly studied, and in other countries State assistance has been most effectually granted, and the clinics have published for a number of years results indicating complete success, with no recurrence after a lapse of five years, in addition to many thousands of "relative" cures, where the immediate effect, without symptoms, is noted under the period of five years.

No one has had greater experience of operative surgery than Howard Kelly, of Johns Hopkins University, who says:—

"It is generally agreed among the leading lights that present-day gynæcology is certainly both medical and surgical, and that radium has possibilities that the general rank of the profession fails to grasp."

In your own columns recently there have been a number of most encouraging articles, summed up in moderate and chastened language in a leading article on May 12th. Surely in this year of grace it would be much more helpful and hopeful to all sufferers from carcinoma if these could be induced to come forward at the earliest moment with a hope of painless cure by short-wave radiations? I should like to make only one more quotation, and that from Manchester:—

"Undoubtedly one of the greatest obstacles to the successful treatment of malignant disease is the fact that the patient—of the hospital class, at any rate—dreads an operation. If, as the result of further experience of radium treatment in this particular situation, it can be shown that there is an appreciable chance of a cure with but little risk to the patient, and if in addition he realises that no mutilation is involved, this type of patient will present himself at an earlier stage for treatment."

I am, Sir, yours faithfully,

DEATHS IN THE SERVICES.

Deputy Inspector General of Hospitals and Fleet William Digby Longfield, R.N. (retired), who died May 23rd at Plymouth in his ninetieth year, entered the Royal Navy in 1861 and served as assistant surgeon in the *Octavia* and *Spiteful* during the Abyssinian War of 18 (medal). In 1875 he became staff surgeon and was medical charge of the naval brigade with the sloop *Tenedo* which served in the Zulu War of 1879, and for some tir was the only medical officer at the Lower Tugela. Wh senior medical officer with the Ekowe relief column, he w dangerously wounded at the Battle of Gingihlovo and w specially thanked and twice mentioned in despatches. H was also awarded the Zulu medal and clasp and promot fleet surgeon. In the same year, 1879, he gained t Gilbert Blain gold medal for the best medical journ After a commission in the troopship *Himalaya* in 1891 was appointed fleet surgeon and retired as deputy inspect general in 1893. He held the Greenwich Hospital pensi for good service on the active list.

QUEEN'S HOSPITAL FOR CHILDREN.—The Duke York, who presided recently at the annual meeting of t governors of this hospital, explained that although £100,0 was being appealed for to enlarge the buildings, it w intended to do the work gradually as means became ava able. The endowment income amounts to 5 per cent. of t expenditure and parents' contributions supply a furth 15 per cent. The weekly cost per patient has been reduc from £4 0*s.* 7*d.* in 1926 to £3 16*s.* 1*d.* in 1927.

GENERAL MEDICAL COUNCIL.

SUMMER SESSION, 1928.

PENAL CASES.

TUESDAY, MAY 22ND.

IN accordance with custom, the Council heard the ses in public, and deliberated on their findings in mera.

Reported by the Dental Board of the United Kingdom.

The Case of Alfred Catlow, registered as of 16, West- te, Burnley, "Dentist, 1921," and charged with audulently obtaining £1 each from two club patients r work on dentures which he had not performed. r. Catlow did not appear, and was not represented a legal adviser. The Council directed that his me be erased.

The Case of Laurent Eugene Deprimoz, registered as 89, Whitehorse-road, Croydon, "Dentist, 1921," d charged with abusing his professional position by mmitting adultery with a married woman. The spondent was represented by Mr. F. de Ferrars, structed by Mr. F. Gowen. In the divorce proceed- gs between the lady and her husband professional lationship was not material and had not been entioned. In a statutory declaration given during e inquiry Mrs. Dora Hoyle, a probation officer, had ated that the lady and Mr. Deprimoz had both ld her that their first meeting had been a profes- onal one. Mr. Deprimoz, however, had testified at he had known the lady before her marriage, d that he had never treated her professionally cept to make her one denture as a gift in the early ys of their liaison. He had never had immoral lations with her at his surgery. The Board had so heard the evidence of Mr. Charles David Levick support of the respondent's testimony. The uncil, after hearing the legal representatives on th sides, decided to erase his name from the gister.

The Case of Harry Patrick Jones, registered as of Aberford-road, Woodlesford, Yorks, "Dentist, 21." Mr. Jones had been reported by the Board canvassing for patients through an approved ciety. The Council decided to postpone judgment one year, subject to the usual conditions.

WEDNESDAY, MAY 23RD.

The Cases of (1) *Percy Bateman*, registered as of 3, New Cross-road, S.E. 14, L.R.C.P. Edin., 1906, R.C.S. Edin. 1906, L.F.P.S. Glasg. 1906 (adjourned m May, 1926). (2) *Duncan Miller*, registered as of ebe House, Washington, Co. Durham, M.B., Ch.B. 11, U.Aberd. (adjourned from May, 1927); and *Robert Moore*, registered as of 34, Mawney-road, mford, M.B., Ch.B., M.D. 1905 (adjourned from vember, 1927) were considered by the Council. ese three practitioners had previously been before e Council on charges involving drunkenness, and dgment had been suspended. It was decided to ow all three names to remain on the Register.

The Case of Frederick Joseph William Porter, D.S.O., gistered as of the Army Medical Service, L.S.A. nd. 1889, M.R.C.S. Eng., L.R.C.P. Lond. 1890. ajor Porter had appeared before the Council for omoting his professional advantage by means of tices in the Indian press; the Council had found e facts proved and had suspended judgment for a ar. On hearing his assurances for the future it was cided that his name should remain on the Register.

A False Statutory Declaration.

The Case of Dorothy Cochrane Logan, registered as of Cavendish-place, W. 1, M.B., B.S. Lond. 1912, D. 1915, who appeared before the Council on the lowing charge:—

"That you were, on Nov. 7th, 1927, at the Mansion use Justice Room in the City of London, convicted the following misdemeanour—viz., of knowingly and wilfully making certain statements false in material particulars in a statutory declaration made and declared by you on Oct. 12th, 1927, under and by virtue of the Statutory Declarations Act, 1835, and were fined £100 and ordered to pay £10 10s. costs."

Dr. Logan conducted her own case. In setting out the facts brought forward by the prosecution, the Council's solicitor stated that respondent had desired to draw public attention to the imperfect conditions under which Channel swimming was supervised. She had accordingly entered for the prize of £1000 offered by the *News of the World*, and had determined, if she should not actually succeed in swimming the Channel, to claim that she had and to secure the prize, afterwards returning it and publishing the facts. She had entered the water at Cape Griz-Nez on Oct. 10th, leaving it some two hours afterwards and crossing on the boat that accompanied her, and swimming to shore at Folkestone. On landing she had informed the newspaper concerned by telephone, and next day had signed in the editor's office a statutory declaration, under the Act of 1835, that she had swum the Channel. She had subsequently admitted the falsity of this declaration, and had been fined as set forth in the charge. Mr. Harold Watson, commissioner for oaths, and Mr. George Atkins, his clerk, admitted that no special attention had been drawn in the newspaper office to the fact that the document respondent signed was a legal one. Mr. Watson had not been introduced as a solicitor nor commissioner for oaths.

Dr. Logan, in her evidence and her address, gave the following account of the episode.

She was very sea-sick on the journey across the Channel, and when she arrived off Folkestone on the morning of Oct. 11th, her friend said she was too ill to travel to town. She did, however, drive up, and arrived at the newspaper office still dazed. She found the editor and proprietor present, and was handed a simple typewritten sheet, with a request that she would sign it. She said "Is it all right? This looks a bit solemn; I have no opportunity of consulting my lawyers," and was told it was a mere formality between the newspaper and their insurance office, and that she incurred no responsibility by signing it. Only after she had signed the paper did Mr. Watson step forward, and she then began to fear that she had signed something important, but it was too late to withdraw. She regarded signing the paper as an incident in the part she was acting for a serious purpose. She had no idea whatever that the document had legal significance until she received it back stamped a few days later. When charged at the Mansion House she was unable to bring forward as witnesses those who had been present at the newspaper office; and she therefore pleaded guilty on legal advice. The cheque did not remain in her possession but was put in the custody of her bank, to pay the *News of the World* on demand. The prosecution had never sought to impugn her personal character, nor to suggest that the offence was more than a technical one.

Dr. Logan said she was sorry she had "been such an idiot," but she had never before had occasion to sign a statutory declaration, and had firmly believed that to do so it was necessary to go before a magistrate in court and take an oath.

Mr. Horace Carey corroborated Dr. Logan's statement.

The President said that the Council had also taken account of the explanations given by way of mitigation of the gravity of the conviction, which was a serious one under the Perjury Act, and they had formed the opinion that Dr. Logan had not thoroughly realised her responsibility as a citizen and as a member of an honorable profession to refrain from signing any statement for the truth of which she could not vouch. They believe that her conduct henceforth would be worthy of the profession of which she was a member and had decided not to erase her name from the Medical Register.

THURSDAY, MAY 24TH.

The Case of Harry Simpson Harling, registered as of 102, Skipton-road, Ilkley, L.R.C.P. Edin. 1909, L.R.C.S. Edin. 1909, L.F.P.S. Glasg. 1909, who appeared before the Council on the following charge:—

"That, being a registered medical practitioner, you abused your position by committing adultery with Mrs.

Annie Belton, a married woman, with whose family you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Feb. 16th, 1927, and made absolute on August 31st, 1927, in the case of Belton *v.* Belton and Harling, in which you were the co-respondent. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

This case had been adjourned from the last session at the request of the respondent. There was no complainant. The Council's solicitor stated that respondent had come to Gainsborough in 1914 and had met Mrs. Belton, then Miss Skepper, for the first time in 1916. She had married Mr. Belton in 1919. In September, 1920, respondent had secured a deed of separation from his wife, and the marriage had later been annulled. In 1922 he had begun to attend the Belton family professionally, and in February, 1926, he had attended the youngest boy for an illness. The last day of the attendance had been on Feb. 23rd. On March 18th he had, unknown to Mr. Belton, entertained Mrs. Belton and her sister at supper. Next day he had gone to Lincoln with Mrs. Belton; Mr. Belton had quarrelled with his wife about this incident, and respondent had visited them, as he said in his statutory declaration, to try to settle their differences. Next day Mr. Belton had asked for his account, and on March 31st the Beltons had entered into a deed of separation. On April 20th respondent had sued Mr. Belton for the amount of his bill. In the beginning of May respondent had had influenza, and Mrs. Belton had nursed him; subsequently she had gone to live with him, taking her son and her sister. Respondent urged that he had not committed adultery until long after the professional relationship had been dissolved by his action in the county court, and that his wife and her solicitors had treated him without mercy. Miss Skepper, Mrs. Belton's sister, testified that Mr. Belton had several times made improper advances to her and had offered her money to commit adultery with him. Mr. and Mrs. Belton had been very unhappy together. After deliberation, the Council decided that Dr. Harling had committed infamous conduct in a professional respect, and directed that his name be erased from the Register.

FRIDAY, MAY 25TH.

An Improper Friendship.

Harold Foster Strickland, registered as of 47, Wickham-road, Beckenham, M. 1905, F. 1912, R.C.S. Eng., L.R.C.P. Lond. 1905, appeared before the Council on the following charge:—

"That, being a registered medical practitioner in professional relationship with a married woman, one Mrs. A. B. C., and her family, you abused such position by entering into and, notwithstanding expostulations by Mr. D. E. C., her husband, persisting unknown to him in maintaining a friendship with the said Mrs. C. of an improper character. And that in relation to these facts so alleged you have been guilty of infamous conduct in a professional respect."

Mr. Strickland was represented by Mr. Neilson, instructed by Messrs. Hempsons on behalf of the Medical Defence Union. The complainant, who was referred to throughout the proceedings as Mr. C., was represented by Mr. Carthew, instructed by Messrs. Le Brasseur and Oakley. The facts alleged were that the complainant's family physician had taken respondent as his partner in 1913. Respondent had performed a few minor operations, but the older physician had retained charge of the family until 1924, when Mrs. C. had been confined in his absence and Dr. Strickland had attended; from that time onward respondent had been their sole medical attendant. Social intercourse had begun between the two families about the year 1926, and had been fairly close. In May, 1927, respondent had written to Mr. C. concelling numerous engagements for what he had said was a very private reason. The reason had been an estrangement between respondent and his wife. After that period respondent had visited the house frequently in both a professional and a social capacity without his wife. In Augus Dr. Strickland had visited the C.'s who were o holiday at Seaview. Later in the year Mr. C. ha begun to feel anxious at the friendship that wa springing up between respondent and Mrs. C. A a result of a consultation with his father-in-law, h had approached Dr. Strickland; respondent ha answered that he was glad Mr. C. had been fran that the way to show the world that there wa nothing the matter was to allow his wife an respondent to proceed exactly as heretofore. Th same day respondent had had a heated conversatio with Mr. C.'s father-in-law, and had been show the door; he reported this episode to Mr. C., reiteratin the advisability of his allowing the friendship to co tinue. A few days later Mr. C. had found his wife an respondent at the house of an acquaintance, Mrs. B and had had another conversation with him whic had followed similar lines. On Dec. 24th Mrs. C and Mrs. B. had gone out motoring, Mr. C. remainin at home. Mr. C. had followed them on a bicycle ar found them with respondent in the car. Tha evening Mr. C., after a long conversation with h wife, had written to respondent in most abusiv terms, forbidding him to hold any further commun cation with his wife. When Mrs. C. was in Switzerlan for a holiday in January, Mr. C. had come across letter from the respondent addressed to her, containin expressions of the most unrestrained affectio Adultery was not alleged.

Mr. C. gave evidence proving these statements; answer to a question by the Legal Assessor, he sa that Dr. Strickland had ceased to be his fami physician from Christmas in 1927, the time of th letter complainant wrote to him.

Respondent, in evidence, said that he had fir met Mrs. C. at her mother's house, and had subs quently become acquainted with her brother an sister. He had met Mrs. C. socially, as she had live next door to his partner. Beyond surgical treatmen to an abscess for which his partner had treated h in 1916, he had had no professional relations wit her. The fact that the children of the two household attended the same schools had been the foundatio of the friendship between the two families. Responden had attended Mrs. C.'s confinement in the absenc of his partner, but had left as soon as the baby ha been born. The close terms on which the tw families met in 1926 had owed nothing to his pro fession. He denied ever having met Mrs. C. clande tinely. He did not deny feeling very strong affectio for her, but he had never committed any misconduc with her in the sense that was known to the la Her father, so far from kicking him out of the hous had shaken hands with him. The events of Christma 1927, had been as follows: Mr. and Mrs. C. and friend had come in a car to deliver presents at h nursing-home, where the friend's mother had die He had asked the C.'s in, but Mr. C. had pleaded long round of visits. As he had reached his ow home an hour later the two ladies had arrived the car. It was raining, and he had got into th car with them and they had driven round the neig bouring streets and parted soon afterwards. Th meeting had been entirely unarranged. When had been staying with the C.'s at Seaview Mrs. had just recovered from tonsillitis; she had dislik her gargle and he had prescribed another for her, an a tonic. This had been purely a friendly act, n professional attendance.

Cross-examined, he admitted having correspond with Mrs. C. when she was in Switzerland, but sa he had not done so nor seen her, except with solicito since she had returned. He denied having ev seen her alone or clandestinely, but admitted th friends in whose houses they had met, knowing th affection for one another, had left them alone f periods of a few minutes. In answer to the Presider he admitted that his patients had all been patien of the partnership. Asked whether at Seaview had prescribed for Mrs. C. as her doctor, he answer "No, as her friend."

The President: "You prescribed, then, for another man's patient?"—"No, the local man had finished his attendance." Asked about the estrangement between himself and his wife, he alleged that the relationship had been perfectly normal for 14 years, and that the estrangement had taken place because he had arranged to go to a poker-party with the C.'s in London, and she had not been invited. In answer to a question from the President as to whether his relation with Mrs. C. was the cause of his estrangement from his wife, respondent said that the latter said he had not been playing poker, but had been motoring Mrs. C. about London. Dr. Strickland said he had written the letter because he was in love with Mrs. . He had written one such letter previously, and had used expressions of the kind when he had been with her. It would, however, be unfair to say that the expressions in the letter were the culmination of these short interviews with her in the houses of mutual friends.

Sir Herbert Waterhouse bore testimony to respondent's character as straightforward, honest, and trustworthy, a brilliant surgeon, and a most successful practitioner. He admitted that the letter had amazed him, and he did not think that respondent could have written it at the present time, but that he must have been overwrought and abnormal when he wrote it.

Counsel for the respondent argued that the professional relationship had been quite subsidiary and accidental to the affection of respondent for Mrs. C. He quoted Lord Esher's dictum that, in order to fall within the scope of the definition, "infamous conduct . a professional respect," a medical man must be acting in pursuit of his profession in doing the acts alleged against him. This relationship did not come to that category; there was no "professional aspect." He submitted that when the treatment for certain complaint was over, the relationship of doctor to patient ceased, subject to the payment of the fee. A man could not help becoming fond of a woman, and Dr. Strickland had committed no misconduct. His actions might have been unwise, but they had not been disgraceful or dishonourable.

The Council found the facts proved, and that they amounted to infamous conduct in a professional aspect, and directed that Dr. Strickland's name be erased from the Register.

The Case of Kenneth Albert Wilson, registered as of 8, Wharncliff-street, Scotswood-road, Newcastle-upon-Tyne, L.R.C.P. Edin. 1921, L.R.C.S. Edin. 1921, L.R.F.P.S. Glasg. 1921, who had been summoned to appear before the Council on the following charge:—

"That you were, on March 20th, 1928, at the Central Criminal Court, convicted of the following felony—namely, of using an instrument to procure miscarriage, and were sentenced to 18 months' imprisonment in the Second Division."

Dr. Wilson's legal adviser produced no evidence. The Council directed that his name be erased.

A Charge of Canvassing Dismissed.

The Case of George Howard Shanley, registered as of , Croxdale-terrace, Pelaw-on-Tyne, L.M.S.S.A. 1925. Charges 1 to 8 dealt with certain persons mentioned by name, and were headed:—

"That, being a registered medical practitioner, you have sought to attract to yourself patients either directly or through an agent, and in particular the following persons."

The ninth charge was as follows:—

"That in April, 1927, whilst addressing the Wardley Lodge Meeting of the Durham Miners' Association held in the Miners' Hall, Wardley, you invited the persons present to become your patients."

Respondent was unrepresented.

The complainants were the London and Counties Medical Protection Society. Mr. Carthew, their counsel, stated that respondent had come to Pelaw-on-Tyne, in Durham, and started to practise in March, 1927. There had been two doctors already in the town, Dr. A. B. Stich and Dr. M. L. Thomson, who were partners. On April 3rd these practitioners had written to their society and to the respondent, commenting on the fact that he had not called on them and complaining that a person had been canvassing on his behalf, asking the residents of Pelaw to join respondent's panel or become his patients or members of his sixpenny club; they had threatened him with proceedings before the Council if they heard of any further canvassing after April 5th. Dr. Shanley had replied that anything of the kind had been done without his knowledge through, possibly, the mistaken zeal of a well-wisher, and that a more manly and straightforward action would have been to approach respondent before invoking the aid of the society. On April 10th Dr. Shanley had attended a meeting of the Durham Miners' Lodge at Wadsley. The local secretary had announced that Dr. Shanley wished to address the meeting. Dr. Shanley had then said that he had come into the neighbourhood to build up a practice; he thought the district was big enough to give another doctor a good living, and if anyone wished to become one of his patients he could do so by leaving his name at his call-house, No. 1, Third-street. He also thought it was essential that there should be a colliery doctor to fight compensation cases, and he was not there to run down Dr. Stich and Dr. Thomson. As he was going out he had said that anyone who wanted to change his panel could do so by merely filling up a form or leaving his name and address at the call-house. He had added that many persons had the idea that they must wait six months before changing, but that it could be done at any time. Counsel did not put in the statutory declarations of his witnesses.

Evidence supporting the charges was given by two miners, Charles Dickson and Joseph Ball.

Dr. Shanley, giving evidence on his own behalf, stated that he had been asked to address the lodge meeting by the secretary, from whom he could produce an official letter. Other doctors had been given this privilege on coming to the district. The secretary had told him that there was an impression among the men that, as Dr. Stich and Dr. Thomson were compensation doctors for the colliery, no other doctor could treat compensation cases; he had asked respondent to explain the position of the men towards compensation and the changing of their panel doctors. On being introduced by the chairman, respondent had said: "If you think for one moment that I have come here to discredit or attempt to injure any other doctor, especially Dr. Stich and Dr. Thomson, you are mistaken. I have come to try and make a practice." He had then explained compensation and the method of changing panel doctors in general terms only. The rules for the transfer of panel patients had, he said, been changed five times in the last two years; confusion arose from the discrepancies in the instructions printed on the backs of the cards. He gave another version of the incident related by Ball, and denied the charge of canvassing. Dr. Shanley stated that to his great regret he had been unable to afford to bring witnesses. He put in statutory declarations which testified that he had spoken in very fair terms of Dr. Stich and Dr. Thomson, and had explained compensation and the method of changing panel doctors. He had not invited men to come on his panel. His words had been, "When a man wishes to change his doctor, it is not necessary to wait the time stated on the back of the card."

The finding of the Council was as follows: "The charges under heads 5 and 9 have not been proved to the satisfaction of the Council, and on the others no relevant evidence has been adduced. The case is therefore closed."

MATERNITY HOSPITAL FOR BELFAST.—At a meeting held at Belfast on May 16th, in furtherance of a scheme to build a maternity hospital in connexion with the Royal Victoria Hospital, subscriptions amounting to £15,000 were announced.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, MAY 23RD.

NATIONAL HEALTH INSURANCE BILL.

THE House considered the National Health Insurance Bill on Report.

Mr. CHAMBERLAIN, Minister of Health, moved the second reading of a new clause to amend Section 94 of the principal Act as to special orders. He explained that Clause 19 of the present Bill brought within the purview of the National Health Insurance scheme certain new classes of persons, but it was provided under the clause that by special order particular persons could be excluded from the general rules, those persons not being persons whom it was intended nor possible to insure. If the ordinary procedure were followed with regard to special orders it was very possible that the special order excluding them could not be brought into force until some time after they had been brought into the Act. The object of the new clause therefore was to make the special orders operative forthwith. This would avoid bringing people into insurance and making them pay contributions for a short time when they were going to be excluded from insurance before they would be able to get any benefit.

The clause was read a second time and added to the Bill.

On Clause 4 (Amendment of Section 26 of the principal Act as to subscriptions to charitable institutions),

Lieut.-Colonel FREMANTLE moved an amendment to enable subscriptions to be made by approved societies towards the support of district nurses. He said that if the amendment were left out societies might think that they were no longer allowed to make contributions for this purpose.

Dr. DRUMMOND SHIELS, in seconding the amendment, said that the district nursing associations did very good work, and it was most desirable that approved societies should have the power to contribute to their funds if they so desired.

Sir KINGSLEY WOOD accepted the amendment, which was agreed to.

On Clause 16 (Amendment of Section 75 of the principal Act as to disposal of surpluses),

Dr. VERNON DAVIES moved an amendment to include dispensaries among the charitable institutions to which subscriptions might be made from the disposable surpluses of the societies.

Sir KINGSLEY WOOD accepted the amendment, which was agreed to.

Sir KINGSLEY WOOD moved an amendment providing that a special order could be made to meet the case of share fishermen restricting the right of deducting or otherwise recovering the employer's contribution.

The amendment was agreed to.

Sir KINGSLEY WOOD moved an amendment postponing to Jan. 7th, 1929, the coming into operation of the part of the Bill which relates to deposit contributors who cannot find admission to approved societies because of the state of their health, and who are to be formed into a separate section. He explained that the Ministry had been advised to fix the commencement of the Act on Jan. 1st, 1929, save as regarded the persons dealt with in this amendment. That would give them adequate time to prepare a good many difficult regulations and to consult the various interests.

The amendment was agreed to.

The Report stage was concluded.

Third Reading of the Bill.

Mr. CHAMBERLAIN, in moving that the Bill be read the third time, said that they might congratulate themselves that the measure had had on the whole a very favourable reception and that it had been recognised that its provisions would result in considerable improvement in the administration of the National Health Insurance scheme. He thought that it would be admitted that under Clause 1 the scheme offered very generous and liberal treatment to insured persons who by reason of genuine unemployment had fallen into arrears with their contributions. They had also improved the position of the married woman who had been insured and who ceased to be employed on marriage. She would now have the full sickness benefit of 12*s.* instead of a reduced benefit of only 7*s.* 6*d.*, and there was no reduction in the maternity benefit. As a result of the discussion which had taken place on the question of additional benefits it was now clearly understood and agreed that there were certain kinds of benefits which were of the nature of medical benefits, but were really not suitable for administration by insurance committees, or even by the approved societies. They had to contemplate in future, particularly in the administration of clinics, some of which would be set up under this Bill, an arrangement under which there would be a joint representation of the professional men who were concerned in the carrying out of the service and the approved societies, and he hoped that under the Regulations made under the Bill they would be able to provide more satisfactory administration of those benefits. An opportunity had been taken to insert in the Bill a definite statement which embodied the assurance he had given more than once as to the right of the insured person to free choice of dentist or doctor. Under Clause 16 (3) there was a proviso which specifically stated that Regulations were not to restrict the right of any insured person to obtain treatment from any practitioner, clinic, or other institution with whom arrangements in respect to that form of treatment had been made in accordance with the Regulations. He believed that would receive general acceptance. He regretted that it had not been possible to include an arrangement by which a specialist service could be provided for insured persons. He held very strongly that that was the greatest improvement that could be made at this stage in the general scheme of national health insurance. He hoped that in course of time it might be possible to make arrangements under which they could ensure the provision of specialist advice, but the recommendation of the Royal Commission was accompanied by a proposal that the specialist service should be obtained by means of a pooling of surpluses. That was not a proposal which commended itself to the approved societies generally, and there was a considerable body of opinion in the House which supported the societies in their attitude. Therefore it was not possible to put it forward in this Bill. But they had perhaps made some little advance towards it by adding to the list of additional benefits in the First Schedule No. 16, which dealt with payments to approved charitable institutions where insured persons might get the benefit of specialist treatment, and as it had been represented that would perhaps a little unfair to the private practitioner or private specialist who ought to be allowed to give treatment if approved societies desired them to do so they had made an addition to Paragraph 8 by which a service of that kind should not be within the ordinary scope of medical benefit.

Mr. RHYS DAVIES said that the Bill as it stood was only an instalment of what they ought to get, but the Labour Party were anxious that the Bill should be passed and they would not divide against the third reading.

The Medical Profession and a Statutory Right.

Dr. VERNON DAVIES congratulated the Minister of Health and his department on the success which had attended the Bill which had caused great satisfaction throughout the country. There was perhaps one section of the community who had viewed the Bill with certain suspicions and were still not quite happy as to what might in future years be the result. He referred to the medical profession. Before the National Health Insurance scheme started there was a certain amount of friction and discussion between the approved societies and the medical men, and it was found necessary to include in the first Act certain statutory provisions concerning medical benefit. That statutory right had been retained by the medical profession up to the introduction of the present Bill. The Minister of Health had now withdrawn that statutory right and had given the profession the promise of Departmental Regulation instead. The medical profession, rightly or wrongly, felt that a statutory provision was of very much more value to them than any Departmental Regulation. He had tried to get that view accepted by the Standing Committee, but he had failed. The medical profession therefore viewed the measure with slight misgiving, although they had absolute confidence in the present Minister of Health. They recognised that he would hold the scales absolutely fairly between the medical profession and the approved societies, but the time might come when Mr. Chamberlain would no longer be the Minister of Health, and then the medical profession would be more or less in the hands of a gentleman who might hold different views. It was quite possible that a future Minister of Health might honestly and sincerely think that the proper way would be for the coöperative societies to start a clinic, either for eyes, ears, nose, and throat, and then appoint their own doctor. Under the Act such a minister would be empowered to make regulations to enable that to be done. If such an unfortunate course ever happened it would arouse again all that antagonism between the approved societies and the medical men which was so prevalent in 1911. That was a thing which the medical profession were particularly anxious to avoid. They were anxious that the National Health Insurance scheme should be a success, and that the insured person should receive its full benefits. That could only be done by hearty coöperation between the approved societies, the medical profession, and the State, all working equally for the good of the insured population. They had to recognise that there had been difficulties, and he only hoped that the Minister by his action had not increased those difficulties;

but that he might be right in expecting that the present scheme would be a success, and that the suspicions of the medical profession had not been justified.

Specialist Services.

Dr. SHIELS said he quite agreed with what had been said as to the merits of the Bill as far as it went, but he thought they had a very reasonable complaint that it did not go far enough. As an expression of the recommendations, or as an application of the recommendations of the Royal Commission it was extremely inadequate. It was quite well known that the Royal Commission placed great importance on specialist services, and Mr. Chamberlain had indicated that he also placed the same value on them. It was true the approved societies were not enthusiastic about the proposal of the Royal Commission for providing specialist services; but if that was a right proposal why did the Minister of Health not seek to carry it out? Sir Walter Kinnear, who had control of the Insurance Section of the Ministry of Health, and who was a very great authority, emphasised two years ago that there was an urgent demand and a proved necessity for specialist and consultant services. Sir Walter Kinnear urged the importance and necessity of pooling as the Royal Commission suggested. While no doubt there had been great difficulties, he (Dr. Shiels) thought the Minister had been guilty of a lack of courage in not tackling this question. As long as these services were not provided the National Health Insurance scheme must be considered to be giving to the great mass of the population an incomplete and inadequate medical service. Attempts had been made in the Standing Committee to ensure that the wives of insured persons should have in confinement adequate midwifery services. The Minister of Health and the whole of his department were extremely sympathetic on this subject, and had in hand various schemes dealing with the matter. He understood that some effort was being made to achieve progress in this connexion. While the problem of maternal mortality was very complicated and difficult, everyone was agreed that one thing to be done was to provide adequate midwifery attendance at the time of confinement. It had always been the practice up to now that dental benefit, like other additional benefits, was not provided until five years' membership had elapsed. The result was that they had a very extraordinary position. They had a very inadequate school dental service through which a child could get dental treatment up to the age of 14, and then from the age of 14 to 16 and up to 21 years there were seven years before an effective method of dental service was provided. Dental service should be given early, because it saved a great deal of subsequent treatment. The unfortunate thing was that the present dental service for insured persons consisted almost entirely in taking out teeth and supplying dentures, instead of the service being, as it ought to be, that of stopping and making minor adjustment which would prevent these more serious things being required afterwards. Apart from economy in dental service such treatment would be an economy from the point of view of general health. He had made representations on that matter to the Minister, and he was glad to say that they were being favourably considered. If something could be done on these lines they would have very much greater satisfaction in this Bill, because there was a tendency to concentrate too much in the health insurance scheme on the financial side, and on the side of cash benefits, rather than on the provision of an efficient and comprehensive medical scheme for the insured person.

A Balanced Measure.

Lieut.-Colonel FREMANTLE said if they would look at the way in which the insurance funds were distributed they would find that the first seven of the new additional benefits were cash benefits. All the way through the cash benefits loomed infinitely larger than the benefits in kind.

Hon. Members: Why not?

Lieut.-Colonel FREMANTLE said that the reason was that this was a balanced measure for the improvement of the health of the people. It was balanced between two things—the need of giving financial relief at the time of distress, and the need of giving technical treatment for the cure, and still more for the prevention of the causes of that distress. It was that combined purpose which was the basis of the insurance scheme originally. If it ever led in other directions it was failing in its purpose. He feared that in the scheme now there was too much given in free cash distribution, and not enough in actual treatment. He particularly wanted to show how that applied to maternity. The statutory benefit was originally 30*s.* for maternity, and no professional attendance. That was increased to 40*s.* in maternity benefit and no treatment. It had been increased still more. It was commonly understood that the average was 46*s.* and no treatment. They knew that these people who received this money did not get the best treatment that could be provided, or such treatment as was intended. It was with regard to this question of the rearrangement of the cash benefits under the Bill that those who looked after the health of the community were concerned. They hoped that they might get more and more a professional and proper use made of the National Health Insurance funds, and it was in that hope that they welcomed this Bill as a steady step forward towards the improved health of the people.

The Bill was read a third time.

Board of Survey and Naval Invaliding Cases.

Mr. HORE-BELISHA asked the First Lord of the Admiralty in how many cases the commander-in-chief accepted the decision of the board of survey in invaliding cases in the last 12 months; and in how many cases he overruled the recommendations of the board of survey.—Lieut.-Colonel HEADLAM, Parliamentary Secretary to the Admiralty, replied: So far as I am aware the commanders-in-chief have accepted the decisions of the boards of survey in all cases of invaliding during the last 12 months.

Decrease in Birth-rate.

Mr. THURTLE asked the Minister of Health the average number of births per day for the first quarter of 1928; and whether this average figure represented an increase or a decrease on the corresponding figure for the first quarter of the preceding year.—Sir KINGSLEY WOOD replied: On the provisional figures at present available there were on an average 1847 births registered per day during the first three months of 1928. This figure represents a decrease on an average of eight births per day on the corresponding figure for the first three months of 1927.

Production of Government Lymph.

Mr. RENNIE SMITH asked the Minister of Health how many calves had been used during the past 12 months in connexion with the Government lymph factory at Hendon for the production of lymph.—Sir KINGSLEY WOOD replied: 421 calves were used at the Government lymph establishment for the production of lymph during the year ended March 31st last.

State Grants for Additional Insurance Benefits.

Mr. RHYS DAVIES asked the Minister of Health the amount of the State grant on each of the additional benefits paid by approved societies for the years 1925, 1926, and 1927 respectively.—Mr. CHAMBERLAIN replied: The approximate amount of the State grant on each of the non-cash additional benefits paid by approved societies in England and Wales for the years specified is as follows:—

Description of Benefit.	Amount of State grant.		
	1925.	1926.	1927.
	£	£	£
Dental	97,150	185,590	438,300
Ophthalmic	12,860	25,250	53,510
Hospitals	48,760	37,090	36,760
Convalescent Home Treatment	1,600	7,020	15,950
Surgical Appliances	3,090	5,490	9,520
Want or Distress	1,020	1,380	1,610
Nursing	1,380	1,150	730
Providing Convalescent Homes	1,540	1,570	720
Repayment of Contributions ..	1,620	2,080	2,200
Total	£169,020	£266,620	£559,300

As the cost of additional benefits which take the form of increases of ordinary cash benefits (sickness, disablement, and maternity) is not separately recorded, the amount of the State grant thereon cannot be stated.

THURSDAY, MAY 24TH.

Boards of Guardians and Vaccination.

Mr. LANSBURY asked the Minister of Health whether he was aware that an official medical man at Romford intimated to the guardians and press representatives that they would have to be vaccinated before attending a meeting of the board of guardians recently or undertake to remain in the institution 11 days; and whether such action was in accordance with the Ministry's regulations and orders under which boards of guardians carried on their duties.—Mr. CHAMBERLAIN replied: The hon. Member appears to have been misinformed. An intimation was given to the guardians that it would not be wise for them to visit the guardians institution, in which a case of small-pox had occurred, for the time being, and that it was advisable that guardians attending meetings of the board or committees should be vaccinated; but the notice to which reference has been made in the press was not in fact given. In these circumstances the latter part of the question does not arise.

Persons Entitled to Health Insurance Benefits.

Mr. DAY asked the Minister of Health the estimated number of persons entitled to benefits under the National Health Insurance Acts at Dec. 31st, 1927, or last convenient date, showing the number of men and women who were on the register of approved societies at that date.—Mr. CHAMBERLAIN replied: The number of persons entitled to benefits under the National Insurance Acts at Dec. 31st, 1927, in England and Wales was approximately 14,260,000, of whom 9,210,000 men and 4,620,000 women were on the registers of approved societies. These numbers are exclusive of persons over 65 years of age who ceased on or before Jan. 2nd, 1928, to be entitled to sickness and disablement benefits.

Nursery and Open-air Schools for Delicate Children.

Mr. HOLLINS asked the President of the Board of Education the number of local education authorities which had established nursery schools, open-air residential schools, open-air schools, and schools for mentally defective children, and the respective percentages to the total number of local education authorities, and whether he would consider the desirability of collaborating with the Minister of Health in coördinating the services in respect of mentally defective and delicate and tuberculous children.—Lord EUSTACE PERCY replied: The following is the information asked for. The table shows the number of local authorities who have established schools of the types mentioned:—

	Local authorities.	
	Number.	Percentage of total number.
Nursery schools	8	2·5
Residential open-air schools.. ..	10	3·1
Day open-air schools	41	12·9
Residential schools for mentally defective children	7	2·2
Day schools for mentally defective children	75	23·6

The figures for open-air schools relate only to schools for the education, under open-air conditions, of delicate and debilitated children suffering from non-infectious conditions, including open-air schools which provide medical treatment and care. In addition in a number of areas such as London and Manchester, classes more or less on open-air lines, attached to public elementary schools, have been started for young or delicate children. Residential schools for both mentally and physically defective children are, of course, attended by children from a considerable number of areas. The hon. Member will find details in the Official List (42) of Certified Special Schools. As regards the last part of the question arrangements for coördination in respect of the services referred to already exist between my department, the Ministry of Health, and the Board of Control.

Revision of Washington Hours Convention.

Sir NICHOLAS GRATTAN-DOYLE asked the Minister of Labour whether any statement would be made at the forthcoming meeting of the Governing Body or at the annual session of the International Labour Conference of the position of the Government in relation to the Washington Hours Convention.

Lord Henry CAVENDISH-BENTINCK asked the Minister of Labour whether the Government had drawn up its detailed proposals for the revision of the Washington Hours Convention; if so, whether those proposals had now been communicated to the International Labour Office; and if he would announce what these proposals were.—Mr. BETTERTON, Parliamentary Secretary to the Ministry of Labour, replied: Since I stated the position of the Government to the Governing Body in February, they have adopted a form of procedure for the revision of draft International Labour Conventions. At the meeting next week His Majesty's Government will press for the application of this procedure to the Washington Hours Convention at the earliest opportunity, and if that proposal is adopted they will be prepared in due course to announce in detail their views as to the form that revision should take.

Supply of Milk at Maternity and Child Welfare Centres.

Mr. MALONE asked the Minister of Health for what reason he had issued a circular to the maternity and child welfare centres instructing them that no milk was to be given to mothers and babies where the family was in receipt of poor-law relief; what was the amount spent on milk by the maternity centres throughout the country; and what was the total amount spent on the maternity and child welfare centres, both by way of grant from the Exchequer and by the local authorities; whether the guardians were authorised to spend money on milk for expectant and nursing mothers over and above relieving actual destitution; and whether he was aware that when the guardians made an allowance for milk they were obliged to allow the full retail price of milk, whereas the maternity centres were able to obtain milk for distribution under contract at a reduced price.—Mr. CHAMBERLAIN replied: No such circular has been issued, but I have suggested to certain of the maternity and child welfare authorities that they should reconsider their procedure in dealing with applications for milk and refer applicants who are in receipt of poor-law relief to the guardians, in order to avoid overlapping and waste. As regards the last two parts of the question, it is competent for the guardians in giving relief to decide, on the advice of their medical officer, whether any special need is present, and if so to take account of that need in determining the amount and form of relief. The guardians are in no worse position than a maternity and child welfare authority because they can also purchase milk by contract for distribution to those in receipt of relief.

Institutional Treatment of Tuberculous Children.

Mr. HOLLINS asked the Minister of Health the number of local governing bodies, and the percentage of the whole, which had made provision for the institutional treatment of tuberculous children and mentally deficient children; and whether the education of the children was continued during the time they were in the institution.—Mr. CHAMBERLAIN replied: All tuberculosis authorities include in their schemes for the treatment of tuberculosis provision for the institutional treatment of tuberculous children. Of the 125 local authorities under the Mental Deficiency Acts 21 have made direct provision of institutional accommodation for children, and others have made provision for the accommodation of children by contracting either with the managers of privately-owned institutions or with poor-law authorities. Education is provided for tuberculous children who make more than a brief stay in a sanatorium, and education and training suited to their capacity is in all cases provided for mentally deficient children while they are under care in an institution.

Use of Small-Pox Hospitals as Tuberculosis Sanatoriums.

Dr. VERNON DAVIES asked the Minister of Health if he would state how many small-pox hospitals in this country had during the last three years been used as sanatoriums for tuberculosis cases; in how many of these hospitals had the authorities had to discharge their cases of tuberculosis in order to admit cases of small-pox; was he aware that some of the tuberculosis cases had had to return to their homes as no sanatorium accommodation could be found for them; and what steps he proposed to take to deal with this situation.—Mr. CHAMBERLAIN replied: Twenty-one small-pox hospitals have been used during the past three years for the treatment of tuberculosis, in one case for the summer months only. Tuberculous patients have been removed from six of these hospitals in order to provide accommodation for small-pox cases. Of these six at least three will not again be used for the treatment of tuberculous patients, alternative accommodation having been provided or being in course of provision. I am aware that there is some disadvantage attaching to the use of small-pox hospitals for tuberculous patients, but when it is necessary for these hospitals to revert to their original use every effort is made to find other accommodation for the displaced patients. It is primarily a matter for the local authorities to consider what steps should be taken to avoid the possibility of some of these patients having to return to their homes.

Prescriptive Standard of Grade A Milk.

Mr. FENBY asked the Minister of Health if he was aware that it was possible in England and Wales for a producer of Grade A milk which was below the prescriptive standard required to continue to sell such milk without the local authority having power to withdraw the licence; whether he was aware that in Scotland, if such standard failed to reach the prescriptive standard required for the purposes of the Food and Drugs Act, the licence could be withdrawn and if he would take steps so that the same powers should obtain in England.—Mr. CHAMBERLAIN replied: It is possible in the case of Grade A milk, as of other milk, for an unadulterated sample to fall below the presumptive limits laid down for the purposes of the Sale of Food and Drugs Acts, and in such cases a prosecution under those Acts can be undertaken by the local authority if the facts appear to justify that course. I see no reason for thinking that a power to withdraw a licence would be more effective in securing that Grade A milk is kept up to the presumptive standard.

Voluntary Societies and Slum Clearances.

Viscount SANDON asked the Minister of Health whether he was aware of, and could render any assistance to, the societies which had been organised in various parts of the country for the purpose of undertaking on a voluntary basis schemes for the improvement and clearance of slum areas and the provision of houses at low rentals.—Mr. CHAMBERLAIN replied: I am aware of the valuable work which is being undertaken by these societies. In connexion with their schemes for the erection of new houses it is open to the societies to apply to the local authorities for subsidy under

the Housing Acts of 1923 and 1924 in respect of houses which comply with the conditions laid down. I shall always be pleased to render any assistance possible towards furthering the objects of these societies.

Building on Site of Foundling Hospital.

Sir JAMES REMNANT asked the Minister of Health whether he was aware that the Foundling Estates, Limited, had submitted plans for building on the site of the Foundling Hospital, including a new road which would encroach on the Mecklenburgh and Brunswick garden squares; that the proposed road would cut through the garden enclosures of Caroline-place and Lansdowne-place; and that buildings on the north frontage of Guilford-street would involve the removal of large portions of these two garden enclosures; when he proposed to resume the public inquiry into the London County Council, Holborn and St. Pancras town-planning scheme, adjourned on Feb. 3rd, 1928; and would he exercise his powers to restrain the proposed encroachment upon the garden squares and the destruction of garden enclosures.—Mr. CHAMBERLAIN replied: I have not details of the submitted plans, but the approval of plans for building on the site of the Foundling Hospital rests with the London County Council, and I have no power to prohibit the approval. I have communicated with the London County Council on the town-planning proposals and the resumption of the inquiry depends on whether the Council decide to proceed with the town-planning scheme so far as it applies to the site of the Foundling Hospital.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

CITY OF LONDON.

Dr. W. M. Willoughby, who was appointed medical officer of health on May 17th, has been in charge of the department since Dr. W. J. Howarth's retirement and presents the annual report for 1927.

He states that among the small night population of the city, estimated at 13,010, there were 114 births (birth-rate 8·7) and 150 deaths (death-rate 11·5). Twelve deaths occurred among infants (infant mortality-rate 105), including one death from diarrhœa. The tuberculosis death-rate was 0·92; the cancer-rate 1·84; the respiratory rate, including two deaths from influenza, 1·4, and the rate from heart diseases 2·3. The single maternal death from childbirth was attributed to puerperal sepsis.

The density of the night population was estimated at 19·8 persons per acre, and of the day population, of persons actively engaged in the city, 644·1 per acre.

In view of the biennial epidemic of measles due at the end of 1927 and the beginning of 1928, a warning leaflet was issued through the teachers of the day schools and Sunday schools and the infant welfare centre. At the tuberculosis dispensary, established at St. Bartholomew's Hospital, more use was made of artificial pneumothorax, which was induced in 9 cases with 182 refills. Dr. Willoughby agrees with the city tuberculosis officer, Dr. F. H. Young, that for a large proportion of tuberculous patients employment in a factory especially devoted to them is the only solution. Dr. Willoughby also expresses his approval of the proposal to establish a permanent smoke prevention advisory committee for greater London. The figures given indicate that cremation is gradually gaining ground in this country, but not so rapidly as in Czecho-Slovakia, Scandinavia, Switzerland, and Germany.

Out of 41 milk samples biologically tested on guinea-pigs, 2 gave a positive result for tubercle. Milk samples found unsatisfactory on account of dirt content are reported to the medical officers of health of the districts concerned. Thirty samples of butter served with bread or scone were taken and successful proceedings were instituted in connexion with one sample certified to consist of margarine. Proceedings were also taken with regard to preservative powders used for sausages which were found to contain boric acid. In the case of a sample of margarine containing boric acid and of tinned peas containing sulphate of copper time was given for the disposal of old stock. Inspection showed that the regulations for the cleansing of empty milk churns was receiving satisfactory attention.

Importation and Inspection of Meat.

Interesting figures are given with regard to meat from the Board of Trade statistics. Thus, of 671,796 tons of imported beef 577,916 came from Argentina; of 276,845 tons of imported mutton 136,866 came from New Zealand; of 25,229 tons of pork 15,867 came from the Irish Free State; and of 423,456 tons of bacon 254,080 came from Denmark. The demand for chilled beef as against frozen increases; thus there was an increase of 36,000 tons of "chilled" and a decrease of 25,000 tons of "frozen." The importation of live cattle from South Africa, Canada, and the United States of America is disappearing. Thus the figures for 1927 were 629,001 from the Irish Free State, 7669 from Canada, and 198 from South Africa. This is partly due to the increasing demand and the high prices obtained for imported cattle in the U.S.A. It is suggested that if the U.S.A. opens its ports to chilled beef from South America there would be a rise in the price of Argentine meat at Smithfield which would act as an incentive to British and Irish farmers to produce more home-fed animals. In 1927 there was an increase from Britain and Ireland in the Smithfield returns of 9333 tons of beef and veal, 6722 tons of mutton and lamb, and 14,545 tons of pork and bacon. Much attention has been given to the supply of fresh pork from Ireland and to the instruction of Irish consignors as to the exact type of carcass required at Smithfield.

The question of tuberculous lesions in pig carcasses has been investigated by Dr. Stanley Griffith and Mr. Cornell of the comparative pathology department, Cambridge, and it has been found that 30 per cent. of the lesions examined contained tubercle bacilli of the avian type. A warning is therefore given to pig-feeders that tuberculous infection to pigs may arise from at least four sources—namely: (1) feeding on cow's milk containing bacilli; (2) suckling a sow with diseased mammæ; (3) feeding in pastures with infected cows; (4) feeding with fowls, many of which may be tuberculous.

It is inferred from the amount of diseased meat deposited at Smithfield that many local authorities do not enforce the Public Health (Meat) Regulations, 1924. One inspector, who called at the market, admitted the impossibility of carrying out the regulations, as he had 29 private slaughter-houses to supervise in addition to his other duties. The National Federation of Meat Traders recognised that honourable traders are the losers by this unequal inspection, and ask for a systematic form of inspection throughout the country. Caseous lymphadenitis in Australian sheep carcasses continues to give trouble and shows some increase in New Zealand carcasses and also in Chilian mutton. The Chilian Government, in consequence, have decided to establish a veterinary meat inspection service and temporarily appointed four well-qualified British veterinary officers to go out to Chili to initiate the new service. Much attention is being given to the 1924 regulations, which deal with the more cleanly handling and transport of meat.

A Housing Scheme.

During the year Windsor House, Shepherdess-walk, was completed in accordance with plans prepared by the city engineer and opened. Dr. Willoughby expresses his regret that ill-health and resignation had made it impossible for Dr. Howarth to see through to its fruition the scheme which he had instituted as far back as 1919 for the improvement of the Hutchison-street area. Windsor House covers nearly two acres; the centre of the square is a big garden for adults, while round the whole of the site is a spacious playground for children. The building comprises 104 flats, consisting of two, three, four, and five rooms respectively with a total accommodation for 600 persons. The cost with the land was about £116,000 and has been borne by the City Corporation without assistance from the National Exchequer.

Rat Repression.

Much attention has been given to rat repression from every point of view. One difficulty is that the

law looks to the occupier to provide the remedy, and it is, of course, quite unreasonable to expect an occupier to go to great expense in rendering a building rat proof. The use of bacterial virus has raised some points of interest. Thus the virus used by certain tenants at the Central Meat Market was examined by the city bacteriologist in 1913 and found to be inert. This justifies the efforts of the Danish Government, reported in our columns recently, to keep their bacterial virus at a high pitch of virulence, by the employment of a skilled bacteriologist. Again in 1920 several of the viruses used appeared to be *Bacillus enteritidis* (Gaertner) and raised the question of the possibility of the infection of human food. Of the various kinds of traps used the "break-back" traps appear to give good results, but the varnish traps are best of all. It is pointed out in the report that there is no law to control the use of many deadly raticides such as strychnine, arsenic, and phosphorus.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 19TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 336 (last week 319); scarlet fever, 1717; diphtheria, 999; enteric fever, 53; pneumonia, 1333; puerperal fever, 42; puerperal pyrexia, 109; cerebro-spinal fever, 5; acute poliomyelitis, 5; acute polio-encephalitis, 5; encephalitis lethargica, 20; dysentery, 6; ophthalmia neonatorum, 104. No cases of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 25 counties: London, 10 (Islington 1, Lambeth 1, Wandsworth 7, Woolwich 1); Bedford, 1; Berks, 1; Chester, 1; Derby, 9; Durham, 72 (Gateshead 24, South Shields 39); Essex, 5 (Leyton 4, Wanstead 1); Lancaster, 16; Leicester, 1; Lincoln, parts of Kesteven 5, parts of Lindsey 2; Middlesex, 3; Norfolk, 1; Northumberland, 15; Nottingham, 18; Soke of Peterborough, 1; Somerset, 2; Stafford, 29 (Walsall 21, Stoke-on-Trent 8); Surrey, 8 (Kingston-on-Thames 7, Reigate 1); Warwick, 3; Yorks, North Riding 5, West Riding 66; City of York, 7; Glamorgan, 12; Monmouth, 43.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on May 22nd–23rd was as follows: Small-pox, 30; scarlet fever, 1640; diphtheria, 2099; enteric fever, 31; measles, 1052; whooping-cough, 150; puerperal fever, 13 (plus 13 babies); encephalitis lethargica, 68; "other diseases," 19. At St. Margaret's Hospital there were 16 cases of marasmus, and 9 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were no deaths from small-pox, 5 (2) from enteric fever, 60 (24) from measles, 11 (1) from scarlet fever, 46 (10) from whooping-cough, 27 (7) from diphtheria, 33 (7) from diarrhœa and enteritis under two years, and 65 (11) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London occurred at Salford, West Hartlepool, and Sunderland. Of the 36 fatal cases of measles outside London 5 were reported from Sheffield. Of the 36 fatal cases of whooping-cough outside London 6 were reported from Birmingham, 5 from Liverpool, and 5 from Manchester. During the same week 19 deaths from whooping-cough were reported from Glasgow.

Hitherto the record of deaths from small-pox published in the weekly returns has been restricted to cases in county boroughs and the great towns. In future a supplementary statement will be issued each month giving particulars of deaths in other areas. Thus during the month of April there were outside London and the great towns 4 deaths certified as due to small-pox, either as principal or contributory cause. These were assigned to Malling R.D., Lichfield M.B., Royal Leamington Spa M.B., and Honley U.D.

The number of stillbirths registered during the week was 305 in the great towns—corresponding to a rate of 44 per 1000 births—including 59 in London.

MEDICAL TOUR IN ITALY.—A visit of foreign medical men to Italian spas will take place from Sept. 5th to 21st next. Further information may be had from the Italian Travel Bureau, 16, Waterloo-place, London, S.W. 1

Obituary.

SIR JAMES HODSDON, K.B.E., F.R.C.S. EDIN.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

WE regret to announce the death of Sir James Hodsdon, Consulting Surgeon to the Royal Infirmary, Edinburgh, and formerly President of the Royal College of Surgeons of Edinburgh. He was found dead early on Tuesday morning last in his sleeping-berth on the train by which he was returning to Edinburgh after attending the recent session of the General Medical Council as representative of the Edinburgh College and a member of the Dental Board.

James William Beeman Hodsdon was born in 1858 and received his early education at Sherborne School, whence he proceeded to Belfast, entered Queen's College, and graduated in medicine at the Queen's University in 1881; simultaneously he took the Scottish conjoint qualifications, proceeding in 1883 to take the Fellowship of the Royal College of Surgeons. He then took advantage of unusual opportunities, and carried out much post-graduate work in Paris, Vienna, and London, and returning to Edinburgh was appointed lecturer on clinical surgery at Surgeons' Hall. This appointment was followed by election to the staff of the Royal Infirmary, the great charity which he served for the rest of his life, being at the time of his death the senior consulting surgeon. At the Infirmary he made for himself a high reputation both as clinical worker and as a remarkably clear and effective teacher, and these qualities were recognised by many educational bodies and led to frequent demand for his services as an examiner; in this capacity he was retained at different times by the Universities of Edinburgh, Durham, and Belfast, as well as by the Royal College of Surgeons of Edinburgh, while for a time he acted as chairman of the committee of management of the Scottish Conjoint Board.

As might be expected, his opinions were always received on the General Medical Council with respect, for he had been a member for 22 years, being chosen by the College of Surgeons in 1906 to represent the Corporation in succession to Sir Patrick Heron Watson. His long experience, both as surgeon and teacher, gave him a position from which to express all-round opinions and to look at medico-political questions in the large, and he will be greatly missed by the Council, and at the Dental Board—all the more because of his invariable and quiet courtesy.

In 1914 Hodsdon was elected President of the Royal College of Surgeons of Edinburgh, and at the outbreak of War took a commission as Major R.A.M.C. (T.), being attached to the 2nd Scottish General Hospital. At the close of hostilities, and after repeated mention in despatches, he was made C.B.E. (military), and in 1920 K.B.E. (civil).

Although he was the author of papers on various surgical subjects he was not a man who took readily to literary expression. But his contributions to the Edinburgh Hospital Reports, and the *Edinburgh Medical Journal*, made early in his career, were practical pieces of work, and his record of an experimental inquiry into the influence of the pulmonary blood pressure upon the collapsed lung, published in our own columns, attracted serious attention.

Hodsdon was 70 years of age at the time of his death, though he looked, at any rate until recently, much younger, and the uninterrupted manner in which he discharged his public duties, both on the General Medical Council and the Dental Board, had made his sudden death a shock to many. But at the close of the recent session of the Council it was evident that he was in considerable suffering, and it was contrary to advice that he undertook the long journey on which he died.

Medical News.

UNIVERSITY OF LONDON: *University College.*—Examinations for a Bucknill scholarship and for two exhibitions will begin on June 26th, the subjects of examination being chemistry, physics, botany, and zoology. Candidates' entries, in proper form, should reach the secretary of the College before June 9th.

UNIVERSITY OF SHEFFIELD: *Centenary of the Medical School.*—Although for some years previously there had been medical education of a kind in Sheffield, the present medical school dates from July, 1828, when the foundation of the Medical Institute in Arundel-street was laid, and a medical school with a corporate governing body first came into being. The Faculty of Medicine of the University of Sheffield has therefore decided to celebrate the centenary of the medical school this year, and on July 11th a congregation will be held, at which the Chancellor (the Marquis of Crewe) will receive delegates from the medical faculties of other universities, by whom addresses will be given. Past and present students of the medical school, as well as members of the medical profession in Sheffield and district, and others interested in the welfare of the school, are invited to attend. To mark the occasion the Faculty is about to publish a history of the medical school in Sheffield, written at its request by the late Dr. W. S. Porter.

THE FORTHCOMING CANCER CONFERENCE.—The provisional programme of the International Conference on Cancer, to be held from July 16th to 20th, has been framed. The mornings will be devoted alternatively to general and sectional discussions. Of the former two sessions will be held concurrently at different places—namely, the House of the Royal Society of Medicine and the College of Nursing, on July 17th and 19th, these buildings being conveniently near together. The list of speakers who have promised to contribute to the discussions is impressive. Under the presidency of Sir John Bland-Sutton, Prof. C. Regaud will open the debate on the relative values of surgery and radiation in the treatment of cancer of various regions. Prof. G. Doderlein and Mr. Malcolm Donaldson will deal with the cervix uteri, Sir Charles Gordon-Watson, Mr. W. E. Miles, and Mr. P. Lockhart-Mummery with the rectum, Prof. Burton Lee, Mr. Sampson Handley, and Mr. G. Keynes with the breast, and Dr. D. Quick, Mr. Stanford Cade, and Mr. Douglas Harmer with the buccal cavity. Prof. J. Ewing will open a discussion on the ætiology of cancer, to be followed by Prof. F. Blumenthal, Prof. A. Borrel, Prof. Rhoda Erdmann, and Prof. H. T. Deelmann. Chemotherapy will be discussed by Prof. W. Blair Bell, Prof. F. Carter Wood, Dr. T. Lumsden, and Dr. Burton Simpson. The special sections, to meet on July 18th and 20th, are concerned with radiology, surgery, medicine and diagnosis, pathology, statistics, and public health. In the radiology section biological effects of radium and X rays, with special reference to the factors of wave-length, intensity of radiation, and duration of exposure will be discussed on the first day, Prof. S. Russ presiding, whereas the second day will be devoted to the effects of radium and X rays on the blood vascular and lymphatic systems. In the surgery section the classification and treatment of bone sarcoma will be the subject of communications by Prof. Ewing and Mr. Sampson Handley; while Sir Berkeley Moynihan will address the section on the early recognition and treatment of cancer of the stomach, and will be followed by Mr. Gordon Taylor, Mr. A. J. Walton, Dr. E. I. Spriggs, Dr. A. F. Hurst, Prof. M. Stewart, and Prof. D. P. D. Wilkie. In the section of medicine on July 18th Sir Thomas Horder will consider cancer criteria, and Dr. Hutchison the frequency of intrathoracic tumours, while on July 20th Sir Thomas Horder and Sir William Willcox will open the discussion on diagnostic methods; Dr. A. Leitch will give an address to the pathology section on occupational cancer, and will be followed by Dr. A. Scott, Mr. A. H. Southam, Dr. W. J. O'Donovan, Prof. Schmorl, Dr. A. Sladden, and Dr. L. Cavatard. Prof. M. Greenwood will speak at a joint session of the pathology, statistics, and public health sections on geographical and racial prevalence of cancer. Contributors to other meetings of the statistics and public health section include Dr. T. H. C. Stevenson, Dr. C. Bridge, Dr. S. A. Henry, Prof. de Vries, Dr. Hoffman, Dr. E. L. Kennaway, Prof. E. L. Collis, and Dr. Janet Lane-Claypon. Sir George Buchanan will give an address on public action in regard to cancer. In the afternoons visits will be paid to hospitals and institutions, a liaison officer being appointed who will have charge of each party. Further information may be obtained from the chairman of the Executive Committee, Mr. Cecil Rowntree, at 9, Upper Brook-street, London, W. 1.

UNIVERSITY OF OXFORD.—Sir Farquhar Buzzard, Regius Professor of Physic in the University, has been elected an honorary Fellow of Magdalen College, of which he was formerly a commoner.

THE President of the French Republic has conferred the Cross of Officier de la Légion d'Honneur on Dr. George H. F. Nuttall, F.R.S., Quick Professor of Biology in the University of Cambridge.

ROYAL MICROSCOPICAL SOCIETY.—The annual Pond Life and General Microscopical Exhibition will be held at 20, Hanover-square, London, W., on Wednesday, June 6th, at 7.30 P.M.

NURSES' MISSIONARY LEAGUE.—An At Home of the League will be held on Thursday, June 7th, at 3.15 P.M., at the Church House, Great Smith-street, London, S.W. 1. Sir Maurice Craig will take the chair and the Bishop of Blackburn will give an address. Invitation cards may be had from Miss Richardson, at 135, Ebury-street, London, S.W. 1.

NATIONAL INSTITUTE FOR THE DEAF.—A conference will be held at University College, Gower-street, London, on June 6th, to consider the claims of the deaf and dumb to higher education and technical training. It will be attended by delegates from universities, education authorities, special schools, and welfare societies for the deaf. Lord Charnwood will preside.

INTERNATIONAL DAIRY CONGRESS.—The programme has been issued of the Eighth World's Dairy Congress, to be held in England from June 26th to July 12th. Sessions will be held at the Central Hall, Westminster, from June 26th to 30th, and subsequently at Reading and in Scotland, At the Royal Agricultural Society's show at Nottingham, from July 10th to 14th, there will be special exhibits of dairy machinery.

ULSTER MEDICAL SOCIETY.—The sixth-sixth annual general meeting of this society was held in the Medical Institute, Belfast, on May 23rd, with Dr. J. C. Rankin, the President, in the chair. The following were elected to office for the session 1928–1929: President, Prof. T. H. Milroy; vice-presidents, Mr. S. T. Irwin and Dr. T. M. Tate; hon. secretary, Dr. R. M. Beath; hon. editorial secretary, Dr. J. A. Smyth; hon. treasurer, Dr. J. T. Lewis; hon. librarian, Dr. W. L. Storey; hon. assistant librarian, Dr. S. Simms. Council: Dr. F. M. B. Allen, Dr. W. Burns, Dr. A. J. Dempsey, Mr. P. T. Crymble, Dr. J. C. Loughridge, and Dr. J. W. Peatt.

THE INFANTS HOSPITAL, VINCENT-SQUARE.—The announcement last week of the great generosity of Sir Gomer Berry, the chairman of this institution, in giving £50,000 for the erection of a new maternity block makes timely some information concerning the immediate designs of the committee of management. The following are a few particulars with respect to the proposed enlargement of the hospital. A large site continuous with that of the existing hospital has been acquired in Vincent-square. It is about five times the size of the present site and will give ample room on an island area for the new buildings, which are designed to accommodate about 140 patients. There will be a complete surgical department, with operating theatres, enabling the surgery done in the hospital to be much extended in scope. The accommodation for the infants, who will be of the same age-limit as at present—i.e., up to 5 years—will be on the wardlet system; that is to say, that each baby will be isolated in some form of cubicle, largely consisting of glass, so designed as to prevent the conveyance of infection from one child to another. It is proposed also to construct the maternity block more or less on the same system. Each cubicle will have access to the balcony for open-air treatment. In orientation the building is designed to make the utmost use of natural sunlight, although provision will also be made for the supply of artificial sunlight. The out-patient, special, pathological, X ray, and orthopædic departments will be designed on the most up-to-date and approved systems. It is expected that the building and equipment of the proposed hospital will entail a cost of about £250,000. The maternity block, for the building of which Sir Gomer Berry's contribution of £50,000 is earmarked, is intended to accommodate about 36 lying-in women. The reason for including maternity cases is to ensure that the teaching facilities at the hospital shall afford experience in the feeding and treatment of new-born babies, and in connexion with this a new antenatal clinic is to be added. There will be ample space devoted to the housing of the staff of nurses and probationers that will be required in the enlarged institution.

Lieut.-Colonel J. W. D. Megaw, having been appointed Inspector-General of Civil Hospitals, Punjab, has relinquished his editorship of the *Indian Medical Gazette*, which he has held for the past seven years. Both here and as Director of the Calcutta School of Tropical Medicine he will be sincerely missed.

BRITISH INSTITUTE OF RADIOLOGY INCORPORATED WITH THE RONTGEN SOCIETY.—The following officers have been appointed: President, Mr. G. W. C. Kaye, D.Sc.; vice-presidents, Sir W. H. Bragg, F.R.S., Dr. Robert Knox, and Dr. L. A. Rowden; hon. secretaries, Dr. Stanley Melville and Mr. G. Shearer, D.Sc.; hon. editors, Dr. Robert Knox and Mr. G. W. C. Kaye. The medical members of the council are Dr. A. E. Barclay, Dr. G. B. Batten, Dr. R. M. Beath, Dr. N. Z. Finzi, Mr. C. T. Holland, Dr. J. E. A. Lynham, Major D. McGrigor, Dr. S. G. Scott, and Dr. J. Duncan White.

BELGRAVE HOSPITAL FOR CHILDREN.—Last year 1852 sick children were admitted to the wards of this hospital in Clapham-road, of whom 96 per cent. came from South London, and the remainder from adjacent districts. The out-patients' department dealt with 16,556 children under conditions so crowded that the medical and nursing staffs are greatly hampered and mothers and infants are kept waiting much too long. A site has been acquired near the hospital, large enough for the erection not only of a new out-patients' building sufficient to meet the possible demand for many years to come but also of a nurses' home. A ward of 12 beds is now available for the admission of children of parents of limited means at a fee of 3 guineas a week.

COMMITTEE OF INQUIRY ON LEAD-ETHYL PETROL.—The committee conferred on May 25th with Surgeon-General Cumming, the head of the Public Health Service of the United States of America. Dr. Leake, one of the senior officers of that Service, was also present. The extensive researches which have been conducted in America by the Public Health Service and others for the purpose of ascertaining whether there was any risk of lead poisoning by the use of ethyl petrol were fully discussed. A further meeting will be held in Room 61 on the second floor of H.M. Office of Works, St. James's Park, London, S.W. 1, at 11 A.M. on June 6th, for the purpose of taking evidence from Sir William Pope, F.R.S., Prof. H. B. Baker, F.R.S., and Prof. G. I. Finch. The proceedings at that meeting will be open to the public.

ROYAL MEDICAL BENEVOLENT FUND.—The total sum which has been voted this year in grants to medical men, their widows or orphans who have appealed for help amounts approximately to £4744, as against £3502 during the corresponding period of last year—an increase of £1242. These figures prove that there is a greater demand on the Fund this year that ever before; subscriptions and donations, however, do not show an equivalent increase, for over the same period they have only risen by £500. An urgent appeal is made for subscriptions and donations, which should be sent as soon as possible to the hon. treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1. The following are notes on a few of the cases helped at the last meeting:—

Dr. H., aged 63. Had to give up practice three and a half years ago owing to cataract in both eyes. He is too blind to see patients and can do no work of any kind. During these last three and a half years he has had to maintain himself, his wife, and two young children on his small capital which is now exhausted. The Fund came to his help at the time he was being sued for his water rate and was unable to pay his rent which was in arrears. An emergency grant of £15 was made and a further sum of £40 voted. Assistance is being sought from other charitable funds.

Dr. W., aged 78. Old age and increasing deafness have prevented this applicant from continuing in the profession, and for some time he has been forced to live on capital. Other family troubles have made heavy financial claims upon him so that all his life savings are now exhausted and he has had to apply for the old-age pension of £26 a year. A nephew gives some help. Voted £40.

Widow, aged 56, of M.R.C.S., L.R.C.P. Owing to ill-health the applicant's husband sold his country practice ten years before he died, and from that time up to his death he and his wife had to live on capital. At his death the widow found there was nothing left; his life policies had been mortgaged years before; there were debts and no money to pay for the funeral. The widow had to sell furniture and other privatepossessions in order to meet the expenses. Her son, who is married and has one child, has been able to give a little assistance, but owing to bad trade he can now only contribute 10*s.* a week. Voted £26.

Daughter, aged 59, of M.D. The applicant has been teaching as a governess for 42 years, having started at the age of 17. Now at her present age she cannot get regular employment. Her savings bring in £50 a year. She was unable to save more as she had to help to keep her mother, who was an invalid for the last 12 years of her life. Voted £26.

WARWICKSHIRE MEMORIAL SANATORIUM.—Last week the Bishop of Coventry dedicated an altar and sanctuary which have been built on to the existing schoolrooms at this institution at Hertford Hill, near Warwick. When not in use the altar is divided by a movable screen from the remainder of the building which is used as a concert hall and cinema.

LONDON JEWISH HOSPITAL.—Additions to this hospital at Stepney Green have been opened by the Lord Mayor of London, Sir Charles Batho. The extensions include a children's ward of 12 cots, five separate rooms for accident and observation cases, an extensive casualty department, an X ray room, artificial sunlight and massage departments, accommodation for 35 nurses, and a restaurant.

THE LATE DR. H. M. WALLER.—Dr. Harry Mortlock Waller, who died at Nuneaton on May 16th at the age of 56, was at one time medical officer to the late Rajah of Sarawak and to the Sarawak Government. He qualified as M.R.C.S. Eng. from St. Bartholomew's Hospital in 1918 and was appointed medical officer to the Ministry of Munitions subsequently acting as medical referee to the Ministry of Pensions. He had lived at Nuneaton for the past three years.

DONATIONS AND BEQUESTS.—Among other bequests Mr. William Francis Paul, O.B.E., J.P., of Orwell Lodge Ipswich, left £2500 to the Ipswich and East Suffolk Hospital as to £2000 to endow a bed to be called the Orwell Lodge bed and as to £500 to Samaritan Society of the hospital 200 guineas to the Royal Surgical Aid Society; and £200 each to the Convalescent Home, Felixstowe, and the Croydon Hospital, Felixstowe.

PRESENTATION TO DR. D. S. DAVIES.—On May 24th the staff of the Bristol health department paid a warm tribute to Dr. D. S. Davies, who recently retired after 42 years as medical officer of health for the city. Dr. B. A. I Peters, who took the chair in the enforced absence of the new medical officer, Dr. R. A. Askins, spoke in appreciative terms of Dr. Davies not only as their late chief but as their friend. In particular he had shown the scientific spirit in medicine, and it was to be hoped that he would now have leisure to give the profession as a whole the benefit of his extensive knowledge of epidemiology. Dr. Peters then presented a writing bureau and bookcase to Dr. Davies who recalled, in returning thanks, some of the conditions of work at the beginning of his term of office. Forty-two years ago the only hospitals belonging to the public health authority were two wooden sheds in a stone-yard, one labelled "fevers," and the other "small-pox." When first they had built proper isolation hospitals it had been difficult to get parents to send their children for treatment; now they were not only willing but often insisted that they should be admitted. In conclusion Dr. Davies wished the members of the staff great success in the future under their new chief. After other tributes had been paid by Mr. Robinson, chief inspector, and Dr. J. C. Heaven, the proceedings terminated.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, June 4th.—8.30 P.M., SOCIAL EVENING. Fellows and guests will be received in the Library by the President and Lady Berry. At 9.15 P.M. Mr. C. Leonard Woolley will give an illustrated address on Recent Excavations at Ur of the Chaldees. Music and light refreshments. The Main Library will close at 5 P.M. but readers will be accommodated in other rooms until 6.30 P.M.

WEDNESDAY.—8.30 P.M., SURGERY. Annual General Meeting: Election of Officers and Council. Discussion on Hare-lip, to be opened by Dr. Victor Veau (Paris). Mr. C. H. Fagge, Mr. T. Pomfret Kilner, and others will speak.

FRIDAY.—5 P.M., OPHTHALMOLOGY. (Tea at 4.30 P.M. (Cases at 4.45 P.M.) *Papers* at 5 P.M. Mr. Montague Hine: Report on a Case of Neuro-fibromatosis of the Eyelid, and of a Case in which a Glass Ball Burst in the Socket. Mr. F. Ridley: Lysozyme-antibacterial Body Present in Great Concentration in Tears, and Especially its Relation to the Human Eye. Annual General Meeting at 6.15 P.M.: Election of Officers and Council. The Library will be open until 10 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, June 5th.—5 P.M., Dr. Charles Bolton: The Interpretation of Gastric Symptoms. (First Croonian Lecture.)
THURSDAY.—5 P.M. (Second Croonian Lecture.)

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.
MONDAY, June 4th.—1.30 P.M., Mr. R. J. Cann: Examination of the Pharynx.
WEDNESDAY.—1.30 P.M., Mr. N. MacKeith: Examination of the Larynx.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
TUESDAY, June 5th.—4 P.M., Mr. A. Tudor Edwards: Recent Advances in Surgery of the Chest.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.
THURSDAY, June 7th.—5 P.M., Sir Oliver Joseph Lodge The Uses We Make of the Ether of Space.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, June 5th.—4 P.M., Mr. Kenneth Walker: Treatment of Prostatic Obstruction.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, June 4th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. James Collier: Vascular Disease as it Affects the Central Nervous System.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: The Surgical Aspect of Compression Paraplegia.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: The Nervous Complications of Otitis Media.
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Familial Neuritis Muscular Atrophies.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.
MONDAY, June 4th.—2.30 to 5 P.M., Medical, Surgical and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

NCOATS HOSPITAL, Mill-street, Manchester.
THURSDAY, June 7th.—4.15 P.M., Mr. Platt: Treatment of Fractures with Demonstrations.

NIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
TUESDAY, June 5th.—3.30 P.M. (at the Jessop Hospital), Mr. Stacey: Obstetrical Cases.
FRIDAY.—3.30 P.M. (at the Royal Hospital): Mr. Townrow: Clinical Cases.

ONDON CLINICAL SOCIETY.
THURSDAY, June 7th.—8.30 P.M. (at the London Temperance Hospital), Sir Berkeley Moynihan: Medicine in Art. (Macalister Lecture.)

Appointments.

TEY, D. H., M.S. Lond., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at the Hampstead General and North-West London Hospital.

ALLEN, Florence, L.R.C.P. Lond., F.R.C.S. Medical Officer of Health, Nantyglo and Blaina Urban District Council, Mon.

HITELAW, A. D., M.B., Ch.B. Camb., D.P.H., Assistant Medical Officer of Health for Bradford.

rtifying Surgeons under the Factory and Workshop Acts: CRABTREE, H. V., M.B., Ch.B. Manch (Exeter); and CRAWSHAW, J. W., M.B., Ch.B. Manch. (Tyldesley, Lancaster).

Vacancies.

For further information refer to the advertisement columns.

berta, Canada, Municipal District of Woodford, No. 550, Onoway.—Municipal Doctor. 2000 Dollars.
Saints' Hospital for Genito-Urinary Diseases, Vauxhall Bridge-road, S.W.—Res. Sen. H.S. At rate of £200. Also H.S. At rate of £150.
hton-under-Lyne, Lake Hospital and Darnton House.—Med. Supt., &c. £300. Also Second Res. M.O. £150.
rmingham and Midland Eye Hospital, Church-street.—H.S. £110.
Burnley, Primrose Bank Institution.—Res. M.O. £300.
Cambridge University Pathological Laboratory.—John Lucas Walker Studentship. £300.
City of London Hospital for Diseases of Heart and Lungs.—Two H.P.'s. At rate of £100.
Coventry, Coventry and Warwickshire Hospital.—Res. H.S., also Res. H.P. Each at rate of £125.
Dorchester, Dorset Mental Hospital, Herrison.—Jun. Asst. M.O. £300.
Dreadnought Hospital, Greenwich.—H.P. and H.S. At rate of £110.
Durham County Hospital.—Jun. H.S. At rate of £120.
Elizabeth Garrett Anderson Hospital, Euston-road.—H.P., Obst. Asst. also 2 H.S.'s. each at rate of £50.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. At rate of £150.
Hastings, Royal East Sussex Hospital.—Hon. Asst. Surg.
Hospital for Sick Children, Great Ormond-street, W.C.—Med. Reg. £250. Also H.P. and H.S. Each £50.
Hove, Lady Chichester Hospital.—H.P. At rate of £100, also Jun. At rate of £50.
Ipswich, East Suffolk and Ipswich Hospital.—Hon. Asst. Ophth. S.
King's College Hospital, Denmark Hill, S.E.—Jun. Aural S.
Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. Med. Supt. £250.
L.C.C. Mental Hospitals' Service.—Eighth Asst. M.O. £300.
Manchester Ancoats Hospital.—H.S. At rate of £100.
Manchester Babies Hospital, Burnage lane, Levenshulme.—Jun. M.O. At rate of £50.
Manchester, Baguley Sanatorium.—Asst. M.O. £350.
Manchester City.—M.O. £600.
Manchester Royal Infirmary.—Dickinson Research Travelling Scholarship in Medicine. £300.
Manchester Royal Infirmary.—Asst. M.O. to Dermatological Department. £20.
Margate, Royal Sea Bathing Hospital.—Two H.S.'s. Each at rate of £100.
Middlesex Hospital and Medical School.—Med. Registrar. £300.
Miller General Hospital for South East London, Greenwich-road, S.E.—H.P. At rate of £125.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Nottingham City Mental Hospital.—Deputy Med. Supt. £650.
Oldham Royal Infirmary.—3 H.S.'s. Each at rate of £175.
Plumstead and District Hospital, High-street, S.E.—First Asst. M.O. £400.
Queen Mary's Hospital for the East End, E.—H.P.'s, H.S.'s, &c.
Royal Chest Hospital, City-road, E.C.—Med. Reg. £50.
St. Andrew's Hospital, Dollis Hill, N.W.—Res. M.O. At rate of £150.
St. Mary's Hospital, W.—Asst. Director to Surgical Unit. £750.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—Clin. Assts.
St. Thomas's Hospital Medical School.—University Chair of Dietetics. £1000.
Shrewsbury, Berrington Hospital.—Res. M.O. £200.
Southport General Infirmary.—Jun. H.S. £150.
South Shields, Ingham Infirmary.—Sen. and Jun. H.S.'s. £200 and £150 respectively.
Swansea Hospital.—H.S. £150.
University of London.—External Examinerships.
University of London, South Kensington, S.W.—Graham Scholarship in Pathology. £300.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Sen. Res. M.O. £250.
Willesden General Hospital, Gynæcological Out-Patient Dept.—Clin. Asst. Surgical Out-patient Dept. 2 Clin. Assts.

Births, Marriages, and Deaths.

BIRTHS.

BUSH.—On May 25th, at 5, Lansdown-place, Clifton, Bristol, the wife of Dr. Gilbert Bush, of a son.
GOOD.—On May 24th, at Farquhar-road, Edgbaston, the wife of Dr. J. Percy Good, of a son.
ROACHSMITH.—On May 22nd, wife of Dr. C. E. Roachsmith, of Landguard, Sawbridgeworth, Herts, of a son.
STIRLING.—On May 15th, at Corringway, Golders Green, N.W., the wife of Major A. Dickson Stirling, D.S.O., R.A.M.C., of a daughter.

MARRIAGES.

MCALLEY—JONES.—On May 19th, at Normacot Church, Longton, Staffs., Robert Ian McAlley, M.B., Ch.B., to Grace Ivernah, only daughter of Mr. Albert E. Jones, Lightwood Chase, Longton, Staffs.

DEATHS.

HODSDON.—Suddenly, on May 28th, Sir James Hodsdon, K.B.E., M.D., F.R.C.S.E., of 6, Chester-street, Edinburgh.
LAWRENCE.—On May 22nd, at 66, Portchester-road, Bournemouth, Sidney Cameron Lawrence, M.B., D.P.H., late M.O.H., Edmonton.
LONGFIELD.—On May 23rd, at Plymouth, Deputy Inspector-General William Digby Longfield, R.N. (retired), in his 90th year.
SMITH.—On May 26th, at Yew Tree Cottage, Alcester, Warwickshire, Thomas Haywood Smith, L.R.C.P., M.R.C.S., aged 85.
WALLER.—On May 16th, at "The Drachenfels," Nuneaton, Dr. Harry Mortlock Waller, in his 57th year.

N.B.— A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

VORONOFF'S METHOD OF REJUVENATION.

THOUGH Dr. Serge Voronoff's method of testicular grafting has long been familiar to medical men in this country through the medium of his books (see THE LANCET, 1927, i., 446), the lecture delivered before the Cambridge Medical Society on May 23rd was the first which he has given in England. An audience of nearly 500 people gathered in the large anatomical theatre of the University to hear the address.

Dr. Voronoff, who spoke in French, began by describing how the increased virility associated with supernumerary testes and the decreased mental and bodily powers of eunuchs had directed his attention to the rôle of the sexual glands in maintaining mental and physical vigour. Attempts to transfer active testes to the scrotum of debilitated animals had failed at first, partly because the blood-vessels forming round them did not penetrate more than about 1 cm. into the transplanted tissue; if layers of graft thicker than this were used the whole behaved as a foreign body and was cast off by the organism. It was possible, however, to make grafts which retained their functional activity, and histological sections of successful grafts made at periods up to four years after transplantation showed that the gland tissue was still normal. His success with testicular transplantation in rams was illustrated by numerous photographs. One of them showed a ram 12 years old—a great age for this species—which was rejuvenated by grafting and had robust offspring. Four years later signs of senility again appeared and a second graft was done with striking results. This ram, said Dr. Voronoff, was still alive and was over 20 years of age, which would correspond to 160 in man. Transplantation of testes in domestic animals had also been done extensively with a view to increasing meat and wool production, and the results were impressive. It had been found that not only was the number of offspring of rams so treated increased by 20 per cent., but the weight of their wool and that of their offspring was greatly increased, the hair being longer, strong, and finer than that of normal animals.

Rejuvenation experiments in man had been first attempted with glands from dogs and rams but the grafts had not taken, and it was only when the testes of chimpanzees were tried that success was attained. Dr. Voronoff showed three photographs of patients before and after treatment, all of which seemed to show a profound change, though it was difficult to say how far this was a true "rejuvenation." One patient was a man who had been in a mental home for senile dementia, and whose mind was so feeble that he could not answer the simplest questions; six months after operation he was able to resume work as a pharmacist. A second was a French architect of 73 who was no longer able to work because he was physically and mentally deficient; three years after the testis of a monkey had been grafted he was able to resume work and said he felt 15 years younger. Dr. Voronoff made the interesting observation that in cases of arteriosclerosis and high blood pressure grafting had the effect of lowering the blood pressure to normal. In women ovarian grafting was found to have much less effect than testicular transplantation in men, but the effect was increased if portions of thyroid and pituitary gland were inserted at the same time, as was his present practice. He explained that it was difficult to get photographs of patients who had been rejuvenated as they were all very reluctant to sit. The lecture concluded with a film demonstrating the technique used in transplanting the testis of the monkey into man.

An account of a discussion of Voronoff's methods in Vienna will be found on p. 1142 of our present issue.

GLASS AS A POISON.

AT a meeting of the Medico-Legal Society on May 24th, Dr. Roche Lynch exhibited samples of powdered glass that had been used in attempts at homicide. One sample, administered in a chupatti, was made of the coloured glass bangles worn by native women; another had been mixed with sugar and given to a non-commissioned officer. It was interesting, in view of the sinister reputation of this substance, to hear that in the opinion of most authorities powdered glass is comparatively harmless. In 1825 a Dr. Jones narrated in THE LANCET how he used to administer it in two-scruple doses as a vermifuge, followed by calomel. Major D. R. Thomas, of the Indian Medical Service, said that out of 2000 poison cases he had observed in four years only one death had been caused by glass, and he did not think that finely powdered glass did any harm. He has seen, in the bazaar at Amritsar, kite-fliers dress their strings with glass powder for a game in which the object is to cut the opponent's line. Children ate sweets with their hands all over the powder, but looked quite healthy in spite of it. This supports the opinions of the compilers of the Ministry of Health's report on glass fragments in food.[1] Large fragments are, of course, another matter; one of Dr. Roche Lynch's samples was taken from the alimentary canal of a suicide, who had died in two hours. The stomach was badly scratched, and the intestine was lined with spicules, but there was no perforation. A diagnosis of cholera was made before closer examination detected the glass. The report emphasised, however, that glass fragments large enough to do damage were extremely rare in food, and Dr. Roche Lynch corroborated the finding that the better the maker the fewer the glass particles. Glass may find its way into bottles and jars during the welding together of the two moulded halves or during the filling of the jar with hot food, and whereas good manufacturers promptly reject faulty containers the less scrupulous ones send them out packed. One of Dr. Roche Lynch's samples consisted of powdered glass combined with arsenic to ensure its efficiency as a poison; in a country like India where arsenic can be bought in any quantity in the bazaar the chemical irritant is naturally more popular than the mechanical. Even in this country, with all its legal restrictions, powdered glass is rarely employed and arsenic very often. At the same meeting Sir William Willcox gave an absorbing account of the Armstrong case, passing round the actual chocolates with which the criminal attempted to poison his professional rival.

HEALTH PROPAGANDA BY PAMPHLETS.

THE Wesleyan and General Assurance Society of Birmingham continues to issue its valuable leaflets on health. The collection we have just received contains several new ones, whilst others show signs of revision. The society is not content with dealing with definite diseases and their prevention but offers general advice on such subjects as diet. Quoting the saying that "diet cures more than the lancet," they have prepared two more leaflets on the Why's and How's of Diet, entitled Points on Buying and Hints for the Cook. Whilst the intelligent housewife will welcome and profit by the information contained, it is less certain that it is worded tactfully enough for the average ruler of the kitchen. The infectious fevers are now mostly covered by separate leaflets, but it would be interesting to see what this enterprising bureau would make of one on small-pox and vaccination. The leaflets are on sale for distribution.

THE HARVEY BANQUET AT THE GUILDHALL.

WE have received a photograph of the centre section of the company present at the Harvey tercentenary banquet given by the Royal College of Physicians of London in the Guildhall on May 16th. The photograph was taken by Photographia, Ltd., who wish to state that, as it was impossible for the majority of those present to see the photographs before the company separated, copies may be obtained from their establishment at 17, Cheapside, London, E.C. The company was photographed in three sections: (1) a centre section, (2) the section on the Chairman's left, and (3) that on his right. The section submitted to us contains many good portraits, and some of our readers may wish to possess an illustrated memorandum of an interesting occasion.

GLYCOSURIA AND LIFE ASSURANCE.

To the Editor of THE LANCET.

SIR,—I was much interested in reading your leading article in THE LANCET of May 26th on the subject of glycosuria and heredity, in particular the concluding paragraph. In the year 1885, when in India, I took out a policy for £100 on my life in the Commercial Union Assurance Company when I was classed as A1. In 1887 I took out another policy in the same company for £500 and was again passed as A1. My examination took place on a Wednesday. On Saturday the same week I went before the medical referee for another company as I had proposed for another policy for £1000. This medical officer refused my life, stating I had diabetes and my life was not worth accepting. I was so astonished, seeing that only three days before I had been passed as A1, that I called on my own medical man, who examined me very closely and said he could find nothing wrong. I interviewed the company with a view to getting them to accept my proposal but was told nothing could be done in the face of their medical man's report. You will note the date 1887. I am still alive, am 72 years old, very active, in perfect health, and not a trace of sugar has ever been found in my system.

Not only has this mistaken report of my case resulted in loss of revenue to the company concerned, but it has done me the injustice of preventing me from getting any free insurance. I had intended taking out policies up to £500, or perhaps more, for the benefit of my wife and children.

I am, Sir, yours faithfully,

May 26th, 1928. G. H.

Croonian Lectures

ON THE

INTERPRETATION OF GASTRIC SYMPTOMS.

Delivered before the Royal College of Physicians of London

BY CHARLES BOLTON, C.B.E., M.D., D.SC. LOND., F.R.C.P. LOND., F.R.S.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

Delivered on June 5th, 1928.

DISORDERS of the gastric functions are amongst the most ancient maladies recorded in medical literature, and yet no general agreement has hitherto been reached as to their classification. Galen [1] was apparently the first observer to arrange them in groups upwards of 2000 years ago. He was dissatisfied with the different meanings which the ancients, as he calls them, gave to the old Greek word "apepsia," which was then in general use. He explains that the digestive function may be conducted weakly although in a normal manner, or it may be definitely disordered, as when the food is changed into some strange matter not useful to the body. He says that the absence of digestion should be called "apepsia," a weak or delayed digestion "bradypepsia," and a disordered digestion "dyspepsia." Such was the probable origin of this vague but expressive term which is in common use to-day. Galen's classification evidently survived into the seventeenth century, for it is adopted by several writers of that period.[2] Subsequently apepsia and bradypepsia dropped out of use, and dyspepsia, instead of being employed as the name of a particular pathological disorder, came to be used as a symptom-complex representing all the maladies to which the stomach is liable. Cullen,[3] for example, in 1784 described idiopathic dyspepsia as being due to local and general causes (food, ill-health, and so on) and symptomatic dyspepsia as due to organic disease of the stomach or of some other part of the body. The same view is expressed in the Dictionary of Medicine by Andral and others [4] in 1837, and it is expressly stated that in all cases the cause is to be sought for. Brinton, in 1864,[5] on the other hand, excludes organic disease from the definition of dyspepsia and regarded it as implying a derangement of function only; and this is the sense in which the term has been most commonly used up to the present time. Dyspepsia has been classified in many ways within recent years; according to the most prominent symptom, the time of onset of the pain, or the character of the eructated material; as to the kind of food or other supposed cause giving rise to the disturbance; as to whether the functions were exaggerated or depressed; and in many other ways. None of these came into general use, although several of the more descriptive terms still survive—for example, "flatulent dyspepsia."

A change took place in the conception of dyspepsia when the modern methods of functional diagnosis began to evolve some 50 years ago. The investigations of the motor and secretory efficiency of the stomach led to the classification of gastric disorders into motor, secretory, and sensory neuroses, each condition being given the status of a separate entity. This proceeding was not justified, because, generally speaking, the neuroses had no clearly distinguishable clinical types of symptoms to correspond with them, and therefore their use never became general, although here again some of the terms survive—for example, "hyperchlorhydria." Neither have our most modern methods of investigation by the X rays and the fractional test-meal supplied us with an explanation of the symptoms of dyspepsia. They have added considerably to our knowledge of the physiology and pathology of the stomach, and are indispensable in the diagnosis of organic disease, and in pointing out the gross changes in function resulting from it. They have, however, shown us that the normal variations in anatomy and physiology are so great that it is usually impossible to say by their use whether any abnormality is present or not in cases of simple functional disturbance. Our methods are imperfect, for the meals administered in the investigations are not such as the patient usually eats, neither is his nervous system at the time of examination in the same condition of irritability as when he is following his vocation. Very often the same appearances may be seen by the X rays whether the patient is in pain or not, for the fine changes in muscular tension responsible for the pain cannot be appreciated by our methods, more especially as hypersensitiveness of the sensory mechanism is an important factor to be reckoned with. A reaction initiated by our surgical colleagues has now taken place. The performance of abdominal operations, quite apart from its aim as a method of treatment, has aided research in many directions, not to speak of independent observations made by individuals. Speaking of gastric symptoms only, it has focused attention definitely upon organic disease and shown that several symptom-complexes formerly described as neuroses are due to this cause. On the other hand, it has demonstrated that these same groups of symptoms may be present in the absence of organic disease, as the operations, at which no demonstrable disease is found or at which the removal of the supposed organic cause has brought no relief to the symptoms, demonstrates. It is thus quite impossible in many cases to distinguish the symptoms due to an organic disease from those exhibited by patients free from such disease, since the same disturbance of function is caused in each case. The conception of dyspepsia has thus returned to that of 200 years ago, and it is now regarded by an increasing number of the members of our profession as signifying a group of symptoms resulting from functional disturbance of the stomach, as a primary affection, or due to organic disease. I believe that this view is the correct one to adopt, and that the leading idea to be kept in mind in investigating a case of dyspepsia should be the exclusion of organic disease. Our first object in diagnosis should be to ascertain the part of the gastric mechanism which is upset and the disturbance in action which it shows; and, secondly, the cause of this disturbance. The first can only be achieved by a thorough examination of the symptoms of the patient, as these afford the most delicate and the earliest available index of disturbed action. In order to do this a clinical classification of dyspepsia is necessary in which the divisions are made into symptom-groups or syndromes, each of which is the clinical expression of the disorder of function of a particular part of the stomach. The second point as to whether the cause of the disturbance is organic disease or not may be settled offhand in many cases; but in view of the fact that organic disease may be latent as regards characteristic symptoms an X ray examination is always necessary, if for any reason it is desirable to exclude such a disease as far as possible. Dyspepsia is one of the most prevalent of disorders, and most cases are examples of simple disturbances of function, so that it is neither desirable nor possible to subject every patient to further examination than that afforded by clinical means, unless there is some good reason for so doing. The danger of missing a serious organic disease of the stomach lies, firstly, in the neglect of a thorough clinical examination; and, secondly, in allowing unrelieved cases to drift as if of no importance instead of resorting to further investigation. Each disorder of function requires a different treatment so that the determination of our first object in diagnosis is necessary before we can cure our patients. The question now arises as to whether it is possible to classify dyspepsia clinically into symptoms which represent the separate disorders of function of the stomach. The miscellaneous and varied symptoms of which the subjects of dyspepsia complain, further

complicated by their different modes of expression and exaggeration, seem to defy classification, and yet the careful observer must perceive that, out of the mass of cases he sees, there are several different combinations of symptoms constantly recurring, which appear to indicate that order and regularity really prevail, but that the outstanding features of a given symptom group are so very often overshadowed by unimportant details that the reverse appears to be the case. One group has already been named the pyloric syndrome, but it lacks definition. I believe that it is possible to classify dyspepsia clinically into such symptom groups and by explaining these in terms of physiology to build up a rational pathological physiology of the stomach.

The stomach has the functions of receiving the swallowed food moderately quickly and of delivering it gradually to the intestine, so that there are two distinct phases during the digestive process at which its functions may be interfered with—namely, during the filling and during the emptying. We know quite well which parts of the stomach are concerned with these two acts and the chain of events occurring during each, so that it should be an easy task to explain the clinical manifestations of the disorders which occur during each phase. This is what I mean by the interpretation of gastric symptoms. The functions of the stomach are so coördinated that it works as a whole and yet a consideration of the symptoms of gastric disturbance suggest that the disorder commonly begins in one part and that this part may remain for long periods the chief centre of irritation, or that the other parts may soon be equally involved so that in all cases we must endeavour to find out if possible where the disorder has begun, as this determines the type of the malady. This entails a careful history of each symptom, not only as to the order of its appearance in the symptom-complex but also as to any changes in its character which has appeared since the illness commenced. It is necessary to have a large number of cases available in order to obtain a sufficiency showing simple combinations of symptoms, from which to form types in the first instance, and finally to explain the more complicated forms. With this end in view I propose to give you the results of a study of a series of 1000 cases of gastric disturbance. My object being to demonstrate the various ways in which the functions of the stomach are interfered with, this series should be free from cases of organic disease. But it is quite impossible to obtain such a series, because we have seen that certain organic diseases produce the same symptoms as those we wish to study, since they upset the functions of the stomach in the same way. Now a disease does this by acting as a focus of irritation to the particular part of the stomach in which it is situated and, so long as it does not structurally alter the stomach may be included in our series with advantage, because it tells us exactly what symptoms to expect when a given part of the stomach is irritated. The truth of the matter is that there are two distinct groups of dyspepsia, defined as we have agreed upon—the symptoms of interference with the functions of the stomach which is (1) structurally normal, or (2) structurally abnormal. There is a fundamental difference between the two, because it is impossible to study the disturbances of normal function in an organ so structurally altered as to be incapable of performing these functions. I refer to pyloric stenosis, hour-glass stomach, leather-bottle stomach, and the various deformities produced by carcinoma, and so on; on the other hand, an uncomplicated gastric ulcer produces its symptoms by acting as a focus of irritation and so interfering with the normal functioning of the part in which it is situated. The type of dyspepsia in which the stomach is anatomically altered can in the majority of cases be excluded. The series of cases I shall deal with, therefore, includes all those patients with gastric disturbance, as they come before the physician, in whom the stomach is capable of performing, and periodically does perform, its functions normally. Before proceeding to an analysis of these cases I shall first give a brief account of my views upon the mechanism of production of pain, because it is necessary to keep this in mind during the consideration of the symptoms; and also upon the value of local and referred pain as indicating the part of the apparatus affected.

Mechanism of Production of Pain.

Modern research in gastric pathology has shown that the symptoms constituting dyspepsia are not due to alterations in the secretion of gastric juice or in the chemical process of digestion, but to alterations in the motor functions of the stomach. So long as these functions are conducted normally and the stomach empties in the normal time it does not matter whether the gastric juice is increased or diminished in amount; but if the stomach fails to empty itself normally then secondary alterations occur in the gastric contents, which add to or modify the symptoms produced by the motor insufficiency of the stomach.

For a great number of years before it was clearly established [6] that the alimentary canal is insensitive to the ordinary stimuli which produce touch and pain in the skin it was considered that muscular spasm was the cause of some forms of abdominal pain; and now it is almost universally considered that visceral symptoms in general are almost entirely muscular in origin, and only on occasion originate in the mucous membrane.

The *muscular sensations* may be grouped under two headings: (1) *Minor sensations*, expressed as some form of discomfort or as the feeling of a lump, weight, tightness, or fullness. (2) *Pain*, varying in degree from a slight ache to very severe pain and described by the patients in different terms, each expressing the kind and degree of pain they experience. There is no real difference between these sensations, each expressing in a special way some degree of muscular tension. Each minor sensation may develop into pain, sometimes the two alternate at different times, and often the patient cannot say whether the sensation is actually one of pain or not. They are also similar in respect of the time of their appearance and disappearance and of their position. The explanation of the fact that the viscera give rise to pain in morbid conditions and yet are insensitive to ordinary stimuli was first supplied by Sherrington.[7] He explains that the ordinary stimuli are not such as produce visceral pain in these conditions and that the stimulus to do so must be of a certain kind—that is to say, it must be an adequate stimulus, a stimulus for which the part of the reflex arc concerned has a selective excitability. The adequate stimulus which causes pain is a distensile stimulus, and if the viscus is distended with fluid pain results.

The first systematic observations upon this subject were made by Hurst and his colleagues.[8] They distended various parts of the alimentary canal slowly by the balloon method, and found that at a certain pressure varying in the different regions a sensation of fullness and distension was felt by the patient; if, however, the balloon was rapidly inflated pain resulted which was slowly replaced by a sensation of fullness, without any accompanying fall in pressure. They concluded that there was no essential difference between the mode of production of each, and that the cause was tension exerted on the muscular coat, owing to the rise of internal pressure, actual pain being caused by the rapidity of inflation. I believe that this explanation is correct, and that excessive muscular tension is the cause of the pain. The excessive tension may be due to internal stretching or to muscular contraction. In whichever of these two ways the tension is brought about the effects of increased muscular tension are the same, but in its production two different reactions are involved. In each reaction the muscular tension is the resultant of one force due to stretching and another due to muscular contraction; but in the one case the primary cause is the stretching and the tonus reaction a secondary effect; and in the other case the primary cause is the excessive muscular contraction and the stretching the

secondary effect of the opposition to contraction by the pressure exerted upon the gastric contents. It is a well-established fact in physiology that stretching acts as a stimulus to smooth muscle, and if the stretching is gradual the muscle elongates up to a certain point, when contractions commence; if rapid, tonic and rhythmic contractions begin at once, but finally disappear if the stretching process is kept up, as in the distension experiments mentioned just now. The excessive tension is never the result of simple passive stretching of the muscle, and in both reactions, whether primarily due to stretching or to muscular contraction, the muscular contraction is really the essential factor and the tension produced in the fibre is an abnormality of the contraction tension. The commonest cause of excessive contraction tension in dyspepsia is increased contraction of the muscle itself and not stretching, because pain due to stretching soon passes off as the muscle accommodates itself. The stomach may be stretched to enormous limits without pain, as in the so-called acute dilatation, which is really an acute distension with fluid. In atonic conditions of the stomach there is no pain because the muscle-fibre is unable to recover its normal tone.

Payne and Poulton [9] have advanced a theory of visceral pain which is opposed to that which attributes it to tension in the muscle-fibre. They found that in cases of more or less prolonged pain there was an increase of the mean pressure within the organ; that when the pain was momentary it was associated with a single muscular contraction and occurred as the muscle relaxed; and that a peristaltic contraction relieved the pain of the distended œsophagus. They concluded that when the wall of an organ is stretched all the structures forming it, muscle-fibres and nerve-endings, take up the tension and that the pain is due to stretching of the nerve-endings that subserve the sense of pain. If the muscle contracts it overcomes the stretch and takes the strain off the nerve-endings, although the tension in the muscle-fibre is further increased by this act. I find it difficult to see eye to eye with Poulton and to interpret the symptoms of dyspepsia by this theory, and for the present at all events must retain the hypothesis that pain is due to an increase in the contraction tension of the muscle-fibre, which assumption, as we shall see, is rendered all the more probable, since it enables us to interpret the symptoms of dyspepsia. Great variations in the contraction tension of the muscle-fibres do not normally occur in the alimentary canal, and Sherrington [10] has explained why this is the case. He shows that a muscle may lengthen or shorten without appreciably lessening or increasing its contraction tension; this form of activity he speaks of as postural. It is essential that the stomach should be easily able to accommodate food received often quickly and in large amount without much alteration in its internal pressure, otherwise there would be an obstacle to the entrance of food. The body of the stomach is able to accommodate itself as it is filled by a lengthening reaction and similarly as it empties and the contents diminish in volume by a shortening reaction. It assumes different postures to suit the volume of its contents without increasing the contraction tension of its muscle-fibres. Similarly, a sphincter which is closing an orifice is in the condition of postural contraction and shows no excess of tension on the muscle-fibres. The excised stomach is able to carry out these reactions although less perfectly than when it is controlled by the finely adjusted balance between its motor and inhibitory nerves. Any interference with this postural adaptation of the musculature results in an increase in the contraction tension of the fibres and discomfort or pain follows. The most important cause of such an interference is irritability of the neuro-muscular mechanism in which state the muscle-fibre reacts too readily and too strongly to stimulation and may become spasmodically contracted. Repeated abnormal stimuli give rise to a permanent irritability and exhaustion is liable to follow, leading to a condition of irritable weakness in which the muscle reacts too readily, but incompletely. This irritability affects both the lengthening and the shortening reactions of the muscle-fibres—that is to say, produces its effects during the filling and the emptying of the stomach. In the former case the muscle refuses to relax in the normal fashion and in the latter contracts too energetically, so that in both cases the internal pressure rises as a secondary effect. When the increased contraction occurs late in the digestive process as the result of excessive stimulation by the gastric contents, filling the stomach puts an end to the symptoms by inducing a normal lengthening reaction. If the muscle is initially irritable a normal lengthening reaction cannot be so well induced by eating and pain occurs as soon as food is taken. Apart from irritability of the muscle there are two other conditions which interfere with the lengthening reaction and produced symptoms as soon as food is eaten. The first is too rapid filling of the stomach, as in bolting the food, whereby time is not allowed for the lengthening reaction to occur. The second is diminished tone in the muscle, which is really a condition of irritable weakness. When the stomach is too rapidly filled the internal pressure acts as a stimulus to contraction, but in all other conditions this internal pressure is entirely dependent upon the energy of contraction. In each case the internal pressure opposes the contraction and thus increases the contraction tension. Since pain appears so much more easily in some individuals than others, or at certain times more than others in the same individual, the stimulus in each case being of the same degree, it is clear that some other factor must be involved, and this factor is the degree of sensitiveness of the nervous system, for pain appears more readily in proportion to this sensitiveness.

In the patient with neuropathic tendencies not only are the reflex motor disturbances responsible for the symptoms more easily excited even by a normal or subnormal stimulus, but their sensory manifestations are exaggerated. Now a surprisingly large number of people have such tendencies without really deserving the name of neuropath, and perhaps most patients as the case progresses show an increasing irritability of the nervous system in a manner which will be discussed later, so that there is no sharp dividing line between the person of average normal stability of nervous system and the neuropathic patient. In both the sensations which are experienced become exaggerated in different degrees and more clearly defined in consciousness as the result of their prolonged continuance and the attention paid to them. The parts in which this factor plays the most prominent rôle are the œsophagus and body of the stomach, because they are more closely connected with consciousness than the pyloric end. Certain normal sensations are received from them which on exaggeration become symptoms of dyspepsia. The act of swallowing can often be felt if the attention be concentrated upon it, particularly if the bolus be larger than usual. The œsophagus can appreciate heat and cold, and a burning sensation on swallowing concentrated alcohol. Hunger sensations, sometimes amounting to pain, and the pleasurable act of filling the stomach concern the body, which also experiences a sense of fullness or distension when a larger meal than usual has been eaten, particularly if swallowed quickly. Voluntary control can be exercised over the cardiac end and gas eructated to relieve the pressure within it. On the other hand, the pyloric end gives no sign whatever to the normal individual that it exists at all. It is only to be expected, therefore, that such sensations should be more easily excited and develop into pain with more moderate degrees of muscular contraction than are responsible for pain at the pyloric end of the stomach.

Local and Referred Pain.

We must now turn to a consideration of the question as to how far it is possible to determine with any degree of certainty by the study of pain whether the œsophagus, the cardiac, or the pyloric region of the stomach is the part of the apparatus disordered. This would be quite a simple procedure if all visceral

pain were local—that is to say, situated directly in the affected part—because it would then be strictly confined to the area of the part. This is, however, not the case, because whenever the contraction tension of the muscle oversteps a certain variable limit referred pain appears, which differs from local pain in that it is often felt at a distance from its source and not only in front but also behind. The relative importance of these two kinds of pain has given rise to considerable discussion more particularly during the last 40 years, and disagreement still exists; so that I must now clearly define my attitude towards this subject.

Local Pain.—The first observer to describe definitely two kinds of pain was Ross[11] in 1888, splanchnic, which was felt in the organ itself, and somatic, which was referred to the wall of the body. Head,[12] in 1905, expresses the view that the viscera possess a low form of sensibility called by him protopathic, whereby they can feel pain and extremes of heat and cold, but these sensations cannot be accurately localised. Mackenzie,[13] on the other hand, denied the existence of local pain. Now there can be no doubt that the minor sensations felt in dyspepsia, the feeling of a lump or weight, or of distension and fullness, or of hunger sensations, are all local. They are all more or less special sensations and are merely an exaggeration of the normal feelings, which everyone now and then experiences. They are never felt in any other position than over the region of the organ producing them, they are never felt in the back, they do not radiate, neither are they ever accompanied by reflex phenomena. It is only reasonable to suppose, therefore, that when these sensations become painful the pain may also be local. The œsophagus localises its sensations fairly accurately, and they are felt in the mid-line of the sternum from the root of the neck to the epigastric angle; this lower point may correspond more or less with the apex of the ensiform cartilage or may be below it if the cartilage is very short. The boundary line between local œsophageal and gastric sensations is naturally indefinite. Local gastric sensations, whether of fullness or hunger, are felt diffusely over the upper abdomen between the ensiform and the umbilicus and more to the left than the right. Both these sensations, fullness and hunger, are particularly concerned with the body of the stomach, so that the above area is that in which body sensations are felt and they are always diffuse and badly localised. When actual pain occurs limited to the central line of the chest, or diffuse and indefinite pain limited to the gastric area, such pain may be local. Although we do not seem to be normally conscious of the pyloric end of the stomach or of the pyloric sphincter, it no doubt causes pain badly localised and indistinguishable from that due to the body.

Referred pain is of much greater importance than local pain, because it is the chief gastric pain, its position is localised and constant, and it should therefore be definitely indicative of the part of the stomach affected. References to it are to be found in the earliest medical literature, and such pains occurring in parts of the body remote from the organ causing them were known as "sympathetic pains." In later times direct anatomical connexions between certain spinal and sympathetic nerves were demonstrated, and it was supposed that in some way or other nerve impulses passed from the one to the other; thus pain occurred in the distribution of the spinal nerves when the anastomosing sympathetic nerves were irritated. No definite explanation, however, was offered as to how the transmission of the impulse was effected. The first observer to enunciate clearly the principle that the transmission was effected in the central nervous system was Dr. S. Martyn, professor of physiology and physician to the hospital at Bristol.[14] In 1864, in discussing the origin of chest pain due to the heart, he writes: "Reflected or radiated pain is now recognised as extremely common. In cases of sensory nerves entering a great centre at the same spot, if the peripheral end of one be irritated, we feel pain in, or refer it also to the periphery of the other." He considered that the impression of some distress in the heart was received through nerves entering the grey posterior columns of the spinal cord, and that the central impression was irradiated and referred by the mind to the sensitive skin. Ross,[11] in 1888, in clearly distinguishing between local and referred pain gives a similar explanation of the latter, for he says that the irritation from the splanchnic nerves is conducted by the posterior roots to the grey matter of the posterior horns, diffuses to the roots of the corresponding somatic nerves, and causes an associated pain in the territory of distribution of these nerves. The particular regions in which œsophageal and gastric pain are felt were first described by Mackenzie[13] in 1892. He also drew attention to associated tender points in the abdominal wall, cutaneous hyperæsthesia, and increased reflex irritability of the recti. Head,[15] in 1893, systematically mapped out the areas of cutaneous tenderness, in which referred pain also occurred, corresponding to each segment of the spinal cord.

These observers considered that a focus of irritation is set up in the spinal cord and that sensory impulses from other parts passing into this segment are so exaggerated as to be painful. According to Head referred œsophageal pain occurs in the fifth and sixth dorsal areas—that is to say, over the lower part of the sternum and occasionally in the seventh area; referred gastric pain occurs in the seventh, eighth, and ninth areas, each occupying about a third of the distance from the ensiform to the umbilicus from above down, and occasionally in the sixth or tenth area. Behind the space covered by these areas extends from the ninth to the twelfth dorsal spines. He advanced the hypothesis that the seventh area corresponds to the cardiac end and the ninth area to the pyloric end of the stomach, but says he has no proof to offer of this supposition. Mackenzie agrees with Head as to the distribution of œsophageal pain, but differs as regards gastric pain, for he limits it to the epigastrium and excludes the supraumbilical region. Neither of these observers supported his contention with a definite series of cases, and no useful clinical scheme to assist in diagnosis has since been evolved. Although it is impossible to say whether œsophageal pain is local or referred unless it extends across beyond the centre of the chest and occurs in the back, in the case of the stomach the very common localised points of pain in the mid-line and along the costal margins are undoubtedly of the referred type because each corresponds to an area of pain at the back; each often spreads out as a band across the abdomen not so much of pain as of tightness, the patient stating that the feeling is as if he were encased in plaster or a tight band or gripped by a vice; each usually shows the point of deep tenderness pointed out by Mackenzie, which assists the patient in localising the maximum point of pain; and at some time or other rigidity of the upper recti will be commonly but not necessarily found. It is quite impossible for gastric pain to be so well localised and to occur over such a small area in a position not directly over the stomach unless it is of the referred type. All these referred pains occurring in the back result from afferent impulses passing up sympathetic fibres from the muscular coat of the organs. The afferent impulses from the *mucous membrane* of both stomach and œsophagus pass up the vagus, so that the local sensations of coldness and burning are accompanied by referred pain in the distribution of the fifth nerve, upper and lower jaw forehead and nose, and so on, in accordance with the relation of the tenth to the fifth nerve as pointed out by Gaskell.[16] These local sensations of the mucous membrane are almost entirely confined to the œsophagus. The temperature sensations of the mucous membrane of the œsophagus are of very little importance in clinical medicine, but the burning and stinging sensation, popularly known as heartburn, is common enough. It is felt beneath the lower sternum and may be reproduced in the normal individual by swallowing concentrated alcohol, but as Hurst[8] has shown hydrochloric acid of the highest strength found in the human stomach is unable to produce this sensation in the normal person. Heartburn cannot be due to the

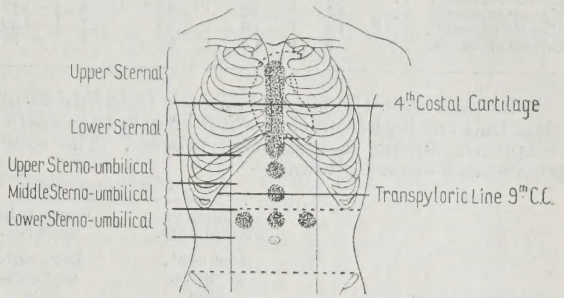
formation of alcohol or other fermentation products in the stomach, because such a condition is practically unknown in functional disorder. It is chiefly seen in cases of so-called hyperchlorhydria, but it is a common experience that, although regurgitation of the highly acid gastric contents is common in this condition, the fauces are usually irritated and not the œsophagus. It must be remembered, however, that regurgitated gastric contents may be retained in the lower œsophagus for some time, which is quite a different matter from a momentary contact with the mucous membrane. Furthermore, in neurotic patients a sensation of soreness or burning may occasionally be felt in the whole œsophagus on swallowing food. This is due to hypersensitiveness of the mucous membrane without a doubt and of the same nature as heartburn. It is therefore probable that when the nerves of the œsophageal mucous membrane become hypersensitive HCl is able to produce heartburn. Sometimes heartburn is associated with severe pain, due to muscular spasm. The chief sensation from the mucous membrane of the stomach is a slight tingling or burning when alcohol is taken, and it is likely that the burning and soreness complained of by neurotic subjects in the epigastrium is due to hypersensitiveness of this structure.

In stating the relative importance of local and referred pain in the diagnosis of the part of the apparatus affected, one may say that in the case of the œsophagus they are of equal usefulness, because each can be localised equally well and they can only be distinguished by the occurrence of pain towards the sides and back. It is a different matter with regard to the stomach, for, although both types of pain occur in the same region, local pain is too indefinite to be of much value as an index of the part affected; on the other hand referred pain, being localised usually to small areas and constant in position, is clearly indicative of the part of the stomach affected. The cases which I shall now describe are not selected, but are taken from my case-books over a series of years in the order in which they occurred in my practice, and form a random series such as appears before every physician, except that the examples of structural deformity which would occur in such a series have been excluded.

Analysis of Cases: Pain.

The most important symptom to be considered is pain in all its varieties. The first point to be determined is whether the position of the pain is a definite indication of the part of the apparatus causing it. The pain areas mapped out by Head are areas of cutaneous hyperæsthesia, which can be marked out fairly accurately. The subjective sensation of pain cannot, however, be outlined in a similar way, unless it is localised to quite a small area. Now I have found the areas of cutaneous hyperæsthesia to be of very small value in diagnosis as a general rule, because they are so uncertain and irregular in occurrence, although now and then one or more complete areas may be marked out. The idea of describing segmental areas of pain had, therefore, to be abandoned as impracticable. The main division into œsophageal and gastric areas presents no difficulty, for the former is the sternal region extending from the root of the neck to and including the apex of the epigastrium; and the latter includes the region below this to the umbilicus. The sternal region appears to be divisible into two parts, an upper and a lower, separated at about the level of the fourth costal cartilage. Referred pain is very frequent in the lower area, but much less common in the upper, although it occurs at times in this position; it does not seem to appear above the second costal cartilage (Fig. 1). The region between the sternum and the umbilicus presents the difficulty that it has no name. From the point of view of referred pain the usual areas into which the abdomen is divided are of little use, however serviceable they may be in other respects. The body wall is segmented into areas corresponding to the segments of the spinal cord and irrespective of the positions of the underlying organs. The part which concerns us—namely, that above the level of the umbilicus—differs markedly from the part below in regard to segmentation. Not only is referred pain more frequent and more clearly defined in this position, but its anatomical segmentation as shown by nerves and tendinous intersections is more clearly marked out. This part above the umbilicus is differentiated before the eighth week of fœtal life; but the lower part is only completed at the end of the twelfth week after the return of the intestine from the extra-embryonic cœlom to the abdominal cavity, to which its late development is probably due (Harris).[17] The anterior body wall is thus naturally divided at the

Fig. 1.



Central positions of referred pain in each of the anterior regions

umbilical level into supra- and infra-umbilical parts. I propose, for purposes of description, to call the upper part the sterno-umbilical region. At first sight it seems impossible to distinguish different areas of pain in such a small region, but it can be done with sufficient accuracy for our purpose by dealing with a large number of cases to eliminate errors, particularly as the areas of referred pain are very commonly no larger than the size of a half-crown piece. It must further be remembered that this region presents the greatest difficulties in diagnosis of any other region of the body, since the pain felt here may be due to almost any organ of the chest or abdomen, in addition to a great variety of other causes. From the point of view of the alimentary canal the lower part of the region is more difficult in this respect than the upper, for it represents both the intestines and the biliary apparatus equally with the stomach. The transpyloric plane cuts the mid-line of this region exactly at its central point and divides it into upper and lower parts. It is usually easy to determine whether the patient points above or below this line to indicate the position of his pain, and he very commonly touches the central point of the line itself—so that the sterno-umbilical region may be thus divided into three parts, an upper, middle, and lower. The position of the pain, whether a small or large area or a band, was marked out on a diagram at the time of examination in every case. The position of the small areas was mostly on the mid-line except in the lower part, in which they were situated quite as often towards one or other side, especially the right. By adopting this method in a sufficiently large number of patients, the error, which in any case must be considerable, was reduced as much as possible.

There are 1009 cases in all, of whom 715 exhibited pain in one area and 294 in multiple areas. The distribution of pain in 624 of the 715 cases is as follows:—

Sternal region	upper	53	cases.
	lower	119	,,
Sterno-umbilical region	upper	223	,,
	middle	152	,,
	lower	77	,,

If these areas really represent the different parts of the œsophagus and stomach from above down, the pain occurring in each position should have a definite time relation to the intake of food depending upon the part affected and the mechanism put out of gear, because the symptoms appear when the apparatus is at work and cease when it is at rest. That pain occurs at different periods of digestion is a very old-established fact, and the replies which patients make to this

question may be divided into four groups. (1) At once or within a few minutes of eating. (2) Half to one hour after food. (3) One hour or more up to seven after food, in which case the patient feels it in the early hours of the morning. (4) Irregularly, that is to say, the symptoms have no clear relation to meals, or are always present to some extent.

By adopting this grouping the time relation to the taking of food in the case of each area is as follows:—

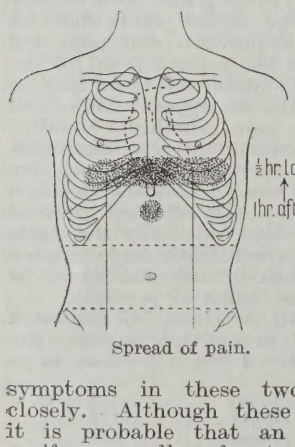
—	At once.	½–1 hr.	1 hr. up.	Irreg.	Cases.
Upper sternum ..	16	5	3	29	= 53
Lower sternum ..	25	26	32	36	=119
Upper st.-umb. ..	47	42	80	54	=223
Middle st.-umb. ..	16	16	93	27	=152
Lower st.-umb. ..	2	5	67	3	= 77

With regard to the time of onset it therefore seems clear that the higher up the pain is situated the earlier it appears during the digestive process. The exact percentages are as follows:—

	Symptoms appearing— At once or thereabouts. Per cent. of cases.	From 1 hr. upwards. Per cent. of cases.
Upper sternum	66·6	12·5
Lower sternum	30·1	38·4
Upper st.-umb.	27·8	47·3
Middle st.-umb.	12·8	74·4
Lower st.-umb.	2·7	90·1

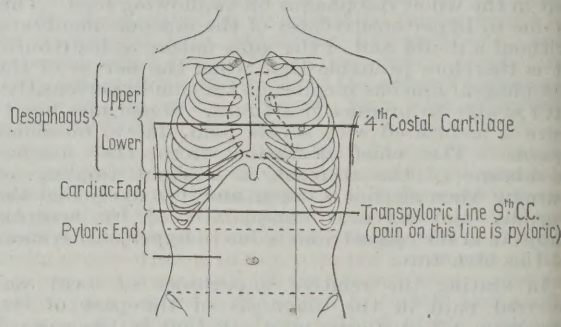
The mechanism of the stomach is likely to be upset at the time when it is subjected to the greatest stress. The part concerned with the filling of the stomach—namely, the œsophagus and body—is likely to be affected in the earliest stage; but that concerned with the emptying of the organ—namely, the body and pylorus at some later stage, when the contents have become irritating, since the more digestible parts leave the stomach first and the acidity is continually rising. So that early pain situated at the highest level should indicate disordered action of the œsophagus and late pain at the lowest level disturbance of the pylorus; whilst symptoms situated at an intermediate position and occurring both early and late should indicate a disorder of the mechanism of the body. The above figures must undoubtedly be interpreted in this way. The œsophagus and body meet at the intermediate position and the cardiac sphincter of the stomach is in fact the lowest part of the œsophagus, hence symptoms referring to the lower œsophagus should partake of the nature of both œsophageal and body symptoms. This appears to be the case, since the time of onset of symptoms in these two parts correspond very closely. Although these two parts must overlap it is probable that an isolated pain below the ensiform usually refers to the body of the stomach, for cases occur in which this pain is followed in a short time by a band of pain across the ensiform and lower sternum, or in which this pain is associated with paroxysms of pain over the ensiform (Fig. 2). Furthermore we shall see later that the relation of each of these areas to the feeling of fullness is different. It is certainly justifiable to draw the following conclusions (Fig. 3). (1) Pain occurring in the upper sternal region usually comes on either at once after food or irregularly and is associated with disordered action of the upper œsophagus. (2) In the lower sternal region it is particularly associated with disorder of the lower part of the œsophagus and appears at once after food or irregularly, but quite as often from one-half to two hours after food. (3) In the upper sterno-umbilical region it indicates disorder of the body of the stomach and appears also at once or irregularly, but rather more often from one-half to two hours after food; the two latter regions indefinitely pass into each other. (4) In the middle and lower sterno-umbilical regions pain indicates derangement of the pylorus and commonly appears more than two hours after food. The middle region shows an appreciable number of cases of pain at once or irregularly, and this region therefore to some extent represents the body of the stomach although it chiefly refers to the pylorus.

FIG. 2.



Spread of pain.

FIG. 3.



Pain region corresponding to each part of the œsophagus and stomach.

A further analysis of the one to two hours' pain shows that in the case of the body more cases show pain in this period than later and in the case of the pylorus the reverse is the case

The following analysis of 361 cases was made:—

—	½–1 hr.	1–2 hrs.	2 hrs. up.	Cases.
Lower sternum ..	9	13	8	= 66
Upper st.-umb. ..	26	33	23	=143
Middle st.-umb. ..	7	27	43	=104
Lower st.-umb. ..	2	18	23	= 48

Pyloric pain, therefore, is more likely than not to appear later than two hours after food.

The part of the apparatus and the mechanism affected is not the only factor which determines the early or late onset of pain, and we must now consider a feature of gastric pain which suggests this to be the case. This character is a tendency for the pain to shift forwards as the case proceeds on its course and to appear sooner after a meal than it did before. This is, of course, most noticeable by the patient in cases in which the pain initially appears late during digestion, but occurs in any type of case and in all positions of pain. The patient, for example, says that the pain used to start half an hour or two hours after food, but now it comes on at once after eating. Sometimes when the pain is moderate in degree it starts late after food, but when very severe it appears at once. Sixteen of the 77 cases of lower sterno-umbilical pain showed this latter feature. The tendency is therefore for any of these pains to become constant, food not affording relief as before and the patient only being free from symptoms first thing in the morning when his stomach is empty. The pain may then come on early or late after breakfast and remain constant for the rest of the day. In some cases when the pain appears early from the beginning it may disappear before the next meal, but eventually tends to become constant like the late pain. All cases do not behave in this manner and many preserve their initial time relation to food for considerable periods, more particularly pyloric cases. The suggestion is that there is some definite cause for this, sometimes operative and sometimes not. It cannot result from retention of the

stomach contents, because, if this were due to secondary atony and diminished peristalsis, any pain caused by the body of the stomach would be lessened; and, if it were due to holding up by the pylorus, this would indicate an increased irritability of the sphincter as the actual cause. It is, in fact, an increased irritability of the neuro-muscular mechanism of the stomach which is the cause. The normal muscular response of the stomach to the presence of food depends upon a nervous reflex, and with constant irritation this responds more easily, and eventually the mere presence of food, however mild, will excite the abnormal movements responsible for the symptoms. This increased reflex response to repeated stimulation is in accordance with a general physiological law and exhaustion is liable to follow eventually, some degree of atony supervening, unless the disorder is put an end to. The central nervous system also becomes irritable and affects the stomach through its extrinsic nerves. This increasing irritability of the nervous mechanism is shown in several other ways. The attacks of dyspepsia tend to become more frequent and prolonged and the symptoms more pronounced in character, although there is no obvious cause to be found except exhaustion or nerve strain. At first diminishing the stimulus by cutting off various articles of food brings relief, but later even the mildest food causes pain, and vomiting starts in bad cases; that is to say, a subnormal stimulus causes an abnormally excessive response. In addition to increased reflex irritability of the neuro-muscular mechanism, hyperæsthesia, as I have already stated, occurs. The attention tends to be more and more fixed upon the symptoms, so that they become more clearly perceptible and exaggerated in consciousness. The ideas the patient forms about his symptoms worry him, and more particularly the idea of serious disease, specially cancer. He imagines that first one foodstuff and then another disagrees with him, and his diet becomes correspondingly restricted. He gathers advice from his friends and the newspapers and tries all kinds of medicines. The symptoms are affected by emotional disturbance and overwork. All these results depend upon one thing only, and that is the degree of stability or irritability of the nervous system of the individual concerned. They occur in varying degrees in most cases of prolonged dyspepsia whatever the type, but are more likely to appear and to be specially pronounced in affections of the œsophagus and body than the pyloric region of the stomach. The œsophagus and body of the stomach, therefore, are liable to develop early and constant pain not only in virtue of their position and functions, but also in virtue of their being already better represented in the central nervous system and more subject to its influence.

A consideration of irregular pain tends to confirm this hypothesis. Here again we find that the upper epigastrium and sternum are more liable to this type of pain than the regions below. The following percentages prove this point:—

Symptoms Appearing Irregularly.

Upper sternum	.. ..	in	54·7 per cent. of cases.
Lower sternum	.. ..	,,	30·2 ,, ,,
Upper st.-umbil.	.. ..	,,	24·2 ,, ,,
Middle st.-umbil.	.. ..	,,	17·7 ,, ,,
Lower st.-umbil.	.. ..	,,	3·8 ,, ,,

The œsophagus and body of the stomach are therefore more liable to irregular pain than the pyloric region. By carefully questioning the patient one can more or less map out this irregular type into three chief groups: (1) The pain occurs either early or late after food. (2) At any time by day or night. (3) Constantly, even when the stomach is presumably empty before breakfast. The first group is fairly equally distributed between the cardiac and pyloric ends and appears, at all events, sometimes to depend on the particular meal eaten; for example, it may appear soon after a small meal and late after a heavy meal; or soon after some particular meal—for instance, tea—and late after the others; or it may come on early if he is worried or tired. The second group in which pain comes on at any time is certainly more likely to affect the body and œsophagus. It is often referred to a cause such as straining movements too soon after meals, stooping to work, sitting in a cramped position, being shaken up in a car or train, lying down at day or night, and above all emotional disturbance. Many of these are the result of increased pressure upon an irritable stomach, or the horizontal position, which induces œsophageal symptoms by regurgitation. The third group of constant pain is certainly more particularly characteristic of a high degree of nervous irritability of the stomach and more particularly affects the œsophagus and body.

It may be stated generally that pain appearing at once or within a few minutes of a meal, or occurring at any time, or constantly is characteristic of excessive nervous irritability of the stomach. There are four further points with regard to pain which are of some interest and importance. The first is the severity of pain in different positions. The two places where the most severe pain is felt are those adjacent to either sphincter, because the contraction tension of the muscle fibres is better opposed in those situations, and spasm is likely to occur. In the upper œsophagus and body of the stomach the pain is more moderate in degree and most often one of the minor sensations. Secondly, paroxysmal pain may occur in quite an irregular fashion at either sphincter, more particularly at the cardia. The patient is usually the subject of dyspepsia, but may have no other symptoms, in which case it is probably of reflex origin. Thirdly, symptoms may occur during the night and wake the patient. Any part of the stomach or œsophagus may be responsible for this, and it is due to three causes.

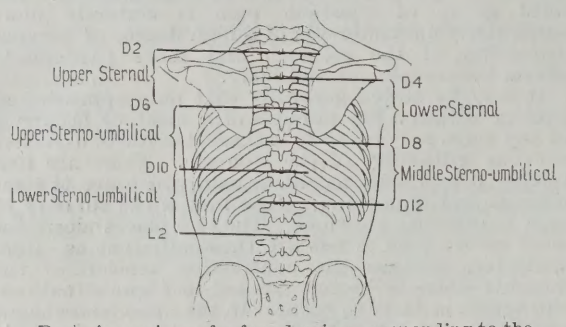
1. It is the variety of pain which comes on late during digestion and then is most often pyloric in type. It merely means that the pain is a severe pain, and it must be remembered that some individuals wake much more easily than others. However, the more severe and regular the pain the more likely it is to be due to organic disease, although pain due to simple functional disturbance not uncommonly wakes the patient.
2. The cause may be regurgitation into the œsophagus of the gastric contents owing to the position of the patient and the respiratory alterations of pressure in the stomach and œsophagus. Such a patient may wake with what he calls heartburn, or waterbrash, or a coughing attack due to regurgitation of gastric contents which irritate the larynx and which may also so irritate the fauces as to make him vomit. In each case he may complain of waking with a pain or curious feeling in the epigastrium in the first instance or not.
3. He may wake with a feeling of great distension, which leads to an attack of nervous eructation. In short, any severe symptom may wake the patient.

Finally, in patients with chronic dyspepsia periods of relative or absolute freedom from pain occur from time to time, and they are also seen when the minor sensations alone constitute the symptoms. Whether the patient is suffering from an organic lesion or simple functional disturbance makes no matter. The free intervals are due to treatment or they are due to re-establishment of the normal stability of the nervous system by rest, holidays, and the like. This applies to patients whether the disorder is painful or not, but if painful it is more noticeable, since they are more likely to take definite steps to get rid of the disorder. Perhaps it may be stated that severe pain recurring over a series of years in the male sex is most likely to be due to an organic lesion, and that patients suffering from minor sensations affecting the body and œsophagus are more likely than any other class to suffer from more or less constant symptoms without much freedom.

Pain in the Back.—The areas given are only approximate, since there is often great difficulty in localising the pain. Each pain area in front has a corresponding position for pain behind. Pain in the back does not occur in all cases of referred pain and never appears alone without pain in the front being felt at some period of the disorder. The areas are usually more extensive and indefinite than the anterior areas though not necessarily so. The pain may be situated in the centre over the spine, across both sides of the back, or more usually on the left side only. Sometimes the areas

are small and appear on the left of the spine in a line with the angle of the scapula. The two pains, front and back, may appear to be separate although occurring together, or the pain in front may seem to go right through the body or round the side to the back. The pain is described as being more or less at the same level in the back as the front, or higher up, but not usually lower down. Of 137 cases of pain in the back 81 corresponded to single areas in front and 56 to other points or combined areas. The 81 cases

FIG. 4.



Posterior regions of referred pain corresponding to the anterior regions.

are considered here—namely, those associated with the anterior areas described above. The levels varied a little in different cases, so that the highest and lowest points in each area were noted and the region included between these levels is described as that corresponding to the anterior area (Fig. 4).

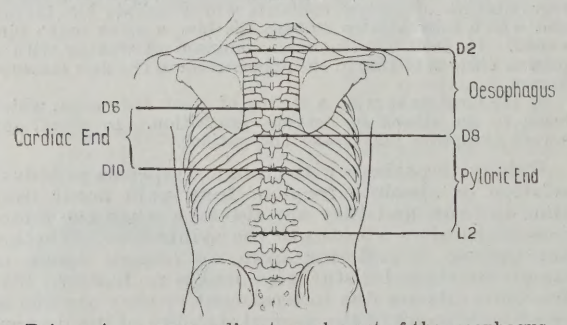
Lower Sterno-umbilical Area.—The lowest point of posterior pain was at about the level of the second lumbar spine. In 13 out of 14 cases the highest point reached to about the tenth dorsal spine and in one to the eighth.

Middle Sterno-umbilical Area.—The lowest point was about the level of the twelfth dorsal spine. In 11 cases the highest point reached to about the seventh or eighth dorsal spine.

Upper Sterno-umbilical Area.—The lowest point was about the level of the tenth dorsal spine. Nineteen out of 26 cases had pain as high as the seventh or eighth dorsal spine and 7 as high as the sixth.

Lower Sternal Area.—The lowest point was about the eighth dorsal spine. Sixteen patients complained of pain

FIG. 5.



Pain region corresponding to each part of the œsophagus and stomach.

as high as the fourth dorsal spine and five as high as the third.

Upper Sternal Area.—The lowest point was about the sixth dorsal spine. Nine patients complained of pain as high as the second dorsal spine.

Expressing these areas in terms of the different parts of the stomach the following result is obtained (Fig. 5):—

Pyloric Region.—This part may be associated with posterior pain from about the eighth dorsal to the second lumbar spine; that is to say, the pain may reach upwards laterally to about the angle of the scapula.

Cardiac Region.—The posterior pain associated with this region of the stomach may extend from about the sixth to the tenth dorsal spine; that is to say, opposite the lower third of the scapula and for some distance below.

Œsophagus.—The upper part shows posterior pain opposite about the upper two-thirds of the scapula and the lower part shows pain opposite about the lower two-thirds.

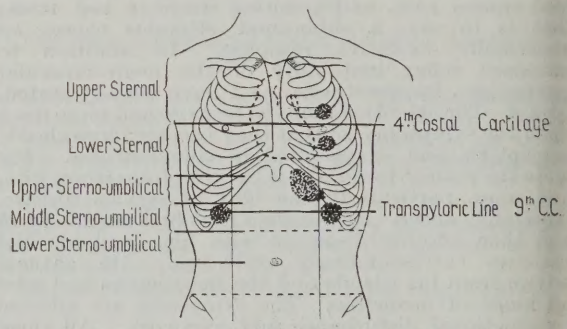
These are the limits of the pain more or less, but it is not as a rule so extensive in any individual case; the area may be quite a small one, or the patient may move the back of his hand up and down over the position in an indefinite manner, or draw his hand across the back to signify the position of the pain.

Radiation of Pain.—In most cases the pain remains localised to the positions described above, but sometimes it radiates in different directions and may be described by the patient as being "like knives."

1. The commonest type is radiation from the front to the positions described at the back. In this type the radiation is usually limited to the particular segment of the spinal cord affected.

2. In another type the radiation affects several segments and in the majority of cases passes upwards from the part affected. It may radiate from any part. It shoots up the centre of the chest or to one or both nipples, more often to the left, or up the costal margin, or up the back. Occasionally the pain shoots downwards; if it is affecting the upper sterno-umbilical area and ensiform cartilage it may shoot down the costal margins or vertically down the centre towards the umbilicus. It is rare for it to invade any segment below the ninth dorsal. In other words, it remains limited to the segments of the spinal cord connected directly with the œsophagus and stomach. Sometimes in a very neurotic patient it may be described as spreading into the limbs.

FIG. 6.



Lateral positions of referred pain in each of the anterior regions

the resistance to spread in the central nervous system being broken down.

3. *Combinations of these radiations* are also found both horizontally, and upwards, or downwards. For example from the lower sterno-umbilical area it may radiate round the sides, through to the back and also up the chest; from the upper area it may radiate up the sternum and down both costal margins; from the lower costal margin it may radiate horizontally and up the costal margin or to the left nipple; and occasionally upwards, downwards, and horizontally like the spokes of a wheel.

This radiation is of no significance except that it definitely points to the stomach as the organ affected in doubtful cases, and the position from which it radiates indicates the most irritable part of the stomach.

Continuing the description of the cases, we have now to consider the remaining 91 cases of localised points of pain; 81 of these occurred at the costal margins and 10 in the region of the nipples. They are as follows (Fig. 6).

	Costal margin.		
	Upper part.	Lower part	(9th c.c.
Right	—	35	= 35
Left	26	14	= 40
Both right and left	—	6	= 6

The most important positions are the lower part opposite the *ninth costal cartilage.* These points lie on the transpyloric plane, where it cuts the costal margins. The size of these areas varies; sometimes they are quite small or they spread out indefinitely up the costal margin and on to the ribs with this point as the centre. There is no doubt that they are particularly connected with the pyloric region of the stomach, and it is quite common for patients to indicate a line of pain passing through the middle of lower sterno-umbilical region and reaching to the side through these points. The points of pain *near the nipples* are quite localised and on the left side usually

nd the patient on being asked to point to the pain uts one or two fingers at the nipple or just above or elow this point.

The following tables show the time relations of the ain in these different positions in relation to meals.

Costal Margin.

—	At once.	½–1 hr.	1 hr. up.	Irreg.	Cases.
eft upper c.m. ..	5	6	10	5	=26
eft 9 c.c.	1	2	9	2	=14
ight 9 c.c. ..	1	1	32	1	=35
ight and left 9 c.c.	—	1	5	—	= 6
					81
ipple region ..	3	—	2	5	=10

Now it is quite clear that the right 9 c.c. area has ıe same time relation to food as the lower sterno-mbilical area: the left 9 c.c. area, and the left and ght combined, are similar though not quite so arked. These two areas, then, should be regarded ; indicating pyloric pain as already stated. On the her hand, the left upper costal margin shows the me characters as the upper sterno-umbilical area id no doubt represents the body of the stomach. his inference might have been drawn since their vels fall within the areas indicating these two regions the stomach. I may mention here in support of is conclusion that the right 9 c.c. area is a frequent osition of pain in duodenal ulcer and the combined ght and left 9 c.c. areas also, but less frequently. he right upper costal margin is usually combined ith the lower portion or occurs as a part of pain in ıe upper epigastric angle. The position of the pain the nipple region indicates that it is of œsophageal igin, and so far as this small number of cases goes supports this conclusion, since the cases showing ain quite soon after food and irregularly are four times numerous as the cases occurring in the period ıe hour and upwards.

The *posterior pain* associated with these positions is agreement with these conclusions.

Lower Costal Margin.—The position of the posterior pain aried between the eighth dorsal and the first lumbar spine, hich is that of pain associated with the pyloric region. ıe right costal margin pain is often associated with left osterior pain.

Left Upper Costal Margin.—The posterior pain occurred om the eighth to the tenth dorsal spine, a characteristic of ain due to the cardiac region.

Inframammary.—The pain corresponding to this position curred between the fifth and eighth dorsal spines, a aracteristic of the lower œsophagus.

Pain above the Nipples.—In one case the posterior pain as felt in the region of the third dorsal spine, a characteristic the upper œsophagus.

Combining the 715 cases of isolated positions of ain, 182 represent the œsophagus, 249 the body of .e stomach, and 284 the pyloric end. This gives the llowing percentages :—

Œsophagus	182	=	25·3	per cent.
Cardiac end	249	=	33·4	,,
Pyloric end	284	=	39·7	,,

It is obvious that these areas of pain in the line of .e nipple and in the costal margin have precisely the me meaning as the central points at about the same vel. It thus appears that there are three lines of calised pains: the first down the centre, the second the line of the nipples and the costal margin, and .e third more or less in the centre at the back or to e left of this in the line of the scapular angle.

Tenderness and Rigidity.—The most important of ese reflex phenomena, because the most constant, e the deep tender points described by Mackenzie and .e muscular rigidity. The cutaneous tenderness scribed by Mackenzie and Head, as I have already ated, I have found to be so uncertain and irregular its appearance and so temporary that it is of little actical use in diagnosis except on occasion. These henomena which occur with referred pain and depend on the same mechanism for their production are most obvious when the pain is at its maximum. They generally outlast the pain and are present between the individual attacks of pain, finally disappearing more or less slowly when a pain period is ended. The reason for this is that the gastric irritability causing the pain does not at once disappear when the pain is relieved, as shown by the great tendency for the pain to recur, unless the treatment is continued for some time. The most marked instances occur in ulcer of the stomach and duodenum, and in the neurotic patient. In the latter case a spread of irritation occurs to adjoining segments of the spinal cord and the whole abdomen may be tender and rigid. Such cases are examples amongst other types of what has been well described by Hutchison as the chronic abdomen. An increased reflex contraction of one or other rectus has the same meaning, and as Mackenzie pointed out when it is present the reflex may be obtained from the skin in the axilla even up to its summit. The deep tender points are usual occurrences with referred pain of any degree of severity. They are felt in the abdominal wall and less commonly in other positions, and correspond in position with the painful points described above. They are a good guide to the localisation of the actual position of the maximum pain. They are much less common at the back. They are thus of great importance in that they are an objective indication of the part of the stomach affected.

The rigidity affects the upper segments of both recti or one only. It is to some extent an indication of what part of the stomach is affected. For example, in a series of 75 cases pyloric pain was associated with a rigid right rectus in 68 per cent. of cases and with rigidity of both recti in 32 per cent., and body pain with rigidity of both recti in 64 per cent. and with a rigid right rectus in 36 per cent. of cases. Rigidity of the left rectus without any increased tension at all in the right does not appear to be common.

The *main conclusions* so far drawn from the study of this series of cases may be summarised as follows.

1. There is no difference between the minor sensations and pain as regards their significance; the one merges into the other, and they are both due to abnormal contraction tension of the muscle-fibre.

2. The position of the pain and the time of its onset after eating definitely indicate the part of the apparatus affected and the mechanism disordered (Figs. 3 and 5).

3. *Pyloric pain* occurs in the following positions: Across the abdomen in the transpyloric line as a band, or as a localised area in the centre, or at one or both ends of this line where it cuts the costal margin (9 c.c.). Across the abdomen between the transpyloric line and the umbilicus as a band or an isolated area in the centre, but quite as frequently to one or other side, particularly the right. Behind the area which may be covered extends from about the eighth dorsal to the second lumbar spine. The pain characteristically occurs late during the digestive process.

4. *Body and Lower Œsophagus.*—The pain occurs at some position between the transpyloric line and the line of the fourth costal cartilage, as a band or localised area in the centre or to one side, particularly in the nipple line or along the upper costal margin. Pain between the transpyloric line and the ensiform definitely indicates the body of the stomach and above this the lower œsophagus, but œsophageal pain may encroach on the stomach area to some extent. Behind, the painful area may occur opposite the lower two-thirds of the scapula and down to about the tenth dorsal spine. In the case of the body of the stomach the pain occurs either in the early stage of digestion, or irregularly, or in the later stages, although not so late as pyloric pain; but œsophageal pain is less likely to occur late than early or irregularly.

5. The *upper œsophagus* is associated with pain above the fourth costal cartilage in front, usually in the centre, and sometimes opposite the upper two-thirds of the scapula behind. It nearly always occurs soon after food or irregularly.

6. The *œsophagus* and body of the stomach are the parts most likely to be affected in the neuropathic patient.

7. As the malady progresses most cases tend to show an increasing irritability of the nervous system, so that there is no sharp line of demarcation separating dyspepsia in the individual of average nervous stability from that in the neuropathic patient.

THE RELATION OF THE ANTERIOR LOBE OF THE PITUITARY TO THE REPRODUCTIVE ORGANS.

By C. W. BELLERBY, M.A.

(From the Biochemical Department, Middlesex Hospital, London.)

IT has long been known that disease of the pituitary body has a marked influence on the activity and development of the reproductive organs.

In 1901, Fröhlich,[1] in describing the condition now known as dystrophia adiposo-genitalis, showed that in addition to obesity and lack of growth there was marked atrophy of the genitalia. Cushing [2] and others confirmed his findings, and a large amount of clinical data has accumulated describing the disturbances of sexual function associated with pituitary disorders. It is of interest to note that, although there has been some difference of opinion as to other symptoms produced by pituitary disease, there is more or less general agreement as to the effect on the organs of reproduction. As to which part of the gland is responsible has been the subject of controversy, but experimental work has now proved the anterior lobe to be the responsible factor. Considerations of space do not allow of an analysis of the clinical evidence, but, in short, it can be said that hypo- or hyper-secretion of the anterior lobe of the pituitary leads to more or less corresponding hypo- or hyper-activity of the ovaries and testes respectively, the consequent effects of which are manifested by symptoms which vary according as to whether the condition of hypo- or hyper-pituitarism arises before or after puberty.

Experimental Production of Hypopituitarism.

It was not until Paulesco [3] devised his operative technique that any real advance was made in the experimental study of the function of the anterior lobe, previous work being of such a nature that little reliance could be placed on the results. Paulesco was the first to show that, whereas no symptoms were produced by removal of the posterior lobe, partial removal of the anterior lobe resulted in adiposity.

It was left, however, to Cushing [2] and his co-workers to recognise that the condition produced in full-grown animals by partial removal of the anterior lobe was identical with the pathological condition, dystrophia adiposo-genitalis. In addition to adiposity there was pronounced atrophy of the uterus, but whilst follicles disappeared from the ovary there was persistence of the interstitial cells. Furthermore, partial removal carried out in young animals resulted in a persistent infantile condition of the reproductive organs. Similar results have been obtained by Aschner,[4] Biedl,[5] Dott,[6] and Blair Bell.[7] The last observer found that there was not only well-marked atrophy of the uterus—both of the muscular coats and of the endometrium—and degeneration of the Graafian follicles, but total disappearance of the ovarian interstitial cells. Blair Bell also observed that separation or clamping of the infundibular stalk was even more effective in causing uterine and ovarian atrophy than partial removal of the anterior lobe. Recently Smith [8] has succeeded in restoring to normal condition the degenerated sexual organs of hypophysectomised rats by grafting into them portions of the gland. The results of these investigators not only proved the endocrine nature of the anterior lobe of the pituitary, but also showed the development and activity of the reproductive organs to be dependent upon its secretion.

Experimental Production of Hyperpituitarism.

In the past investigators have studied mostly the condition of hypopituitarism following partial removal of the anterior lobe, but recently attention has been paid to the effects of injection of extracts or the grafting of anterior lobe as a means of production of anterior lobe hypersecretion. Although various reports of the effects of anterior lobe extracts have been made the first definite evidence of activity was obtained by Long and Evans,[9] who showed that the daily injection of extracts of the gland into female rats caused the immediate cessation of the normal œstrous cycle, the cycle remaining in abeyance during the period of the injections. Examination of the ovaries of these animals killed during the inhibition period showed them to be full of substantial corpora lutea. Long and Evans concluded that their extracts were not only toxic to developing ova, but also had a stimulating effect on the growth of luteal tissue. This was substantiated by Teel,[10] who proved that the corpora lutea were functional in so far as sensitisation of the uterus was concerned, since injury to the uterus was followed by the formation of placentoma.

In contrast to the above results has been the work of Zondek and Ascheim [11] and Smith [12] who showed that full œstrus can be produced in three-weeks' old mice and rats by grafting into them portions of anterior lobe. Zondek and Ascheim [13] were also able to produce the same effects by injection of extracts of the gland. Brouha and Simmonet [14] reported similar findings, though they give no details of the method of preparation of their extracts. These observations show that a substance is elaborated by the anterior lobe of the pituitary which stimulates the formation of functional corpora lutea in the ovaries of normal mature animals and has also a marked effect on the immature ovary, causing it within a few days to attain a state of functional activity which it would not reach normally for some weeks.

Scope of Present Investigations.

During the past year investigations have been carried out in this laboratory, and the main principles recorded by Long and Evans and Teel have been confirmed. It was found, however, that the inhibition of œstrus is not dependent upon the daily injection of extracts, since inhibition periods of two to three weeks could be obtained by the single injection of 1·0 c.cm. or less of certain extracts. The end of the inhibition period is indicated in many cases by bleeding from the vagina. These results are in accord with the observations made by Teel [10] on the formation of functional corpora lutea, since the inhibition period following injection are, on the average, of the same length as those which follow from mechanical stimulation of the cervix of the uterus. Potent extracts can

e made from male anterior lobes, a fact which ıvalidates any claim to specific function on the part f the female gland. It is assumed above that the œstrus-producing" factor of Zondek and Ascheim identical with that of Long and Evans, the difference ı results obtained by these workers being due to the ct that the effects produced by extracts varied cording to the stage of development of the injected imals. In consequence, extracts which are highly tive in inhibiting œstrus should be equally, if not ore, active in producing œstrus in immature animals. his, however, was not found to be the case. Many tracts have been made, and, although they have en remarkably consistent in inhibiting œstrus when jected in small doses, so far no "œstrus-producing" tivity has been detected in any of them.

All the extracts have been prepared by the method scribed by Teel,[10] since the writer has found that tracts which are highly potent as regards "œstrus-hibiting" activity can be consistently obtained by is method. A typical experiment is described below.

Expt. 17.—94·2 g. of anterior lobe tissue dissected from ox pituitaries were ground to a fine paste with sand and oroughly mixed with 100 c.cm. of N/10 sodium hydroxide lution. The paste was allowed to stand on ice for 24 hours d was then neutralised with N/2 acetic acid, phenol red ing used as an indicator. On centrifuging the mixture at gh speed for 15 minutes, 114 c.cm. of turbid pink fluid were tained. The fluid was kept in a freezing mixture during e course of the experiment, a requisite amount being awed out each day for injection. The extract was injected traperitoneally in both full grown and immature animals. Fourteen stock rats, whose cycles, previous to injection, d been perfectly regular for a period of two months, were ch injected with 1 c.cm. of extract for four consecutive ys. Of these 14, two showed no change in the normal ogress of their cycles. The remaining 12, however, owed inhibition periods of 14, 12, 17, 15, 13, 12, 17, 12, , 14, 16, and 18 days respectively. At the same time three-weeks' old rats were injected with 1·0 c.cm. of extract six consecutive days. Of these ten, two died on the st and second days respectively. Of the remaining eight single animal manifested any signs of œstrus, either ring or after the period of injection.

Discussion.

This experiment is typical of others and shows at alkaline extracts of anterior lobe, which prove to definitely active in inhibiting œstrus, have no œstrus-producing" effects when injected into mature animals. In view of the fact that "œstrus-oducing" extracts can be made from anterior lobes employing other methods of extraction, it must concluded that there are two distinct substances volved; one of these produces œstrus in immature imals whilst the other inhibits the normal cycle of ature animals; and, whereas the latter is stable to kali, the former appears to be destroyed or precipi-ed by it.

These results are in accord with those of Long and ans,[9] who failed to promote œstrus in immature rats th their extracts, though opposed to those of Teel.[10] e latter claimed to have produced œstrus with his aline extracts, a finding incompatible with the sults obtained by Zondek and Ascheim,[11] who state at the "œstrus-producing" substance is easily stroyed by alkali. Unfortunately Teel gives no tails of his experiments.

Apart from the fact stated above no evidence in sup-rt of the existence of two substances can be obtained m a consideration of the chemistry of extracts, ce the knowledge so far obtained is not only frag-ntary but contradictory. Teel and his co-workers[15] ntend, for instance, that the "œstrus-inhibiting" bstance is precipitated or destroyed by alcohol, and at the production of a slight acid reaction in an ract also leads to its destruction. These results, wever, are in direct opposition to those of Long d Evans,[16] who obtained active "œstrus-inhibiting" racts by treatment of glands with dilute acetic d or with 50 per cent. alcohol. Moreover, their lier extracts were made by grinding anterior es with saline, and since minced glands become d on standing, this in itself should have led to truction of the activity. The writer also found that active "œstrus-inhibiting" material could be obtained by a method which entailed the extraction of the glands with boiling 5 per cent. hydrochloric acid. If the "œstrus-inhibiting" substance is proved to be stable to acid, it differs in this respect from the "œstrus-producing" substance, since Zondek and Ascheim[13] claim that the latter is unstable to acids. The proof of the existence of two distinct substances would be confirmed if it were shown that the "œstrus-producing" extracts of Zondek and Ascheim and Brouha and Simmonet were devoid of "œstrus-inhibiting" activity. Investigations are now being undertaken in the Pharmacology Department at Cambridge with this end in view. Little advance is likely to be made in our knowledge of the effects produced by extracts of the gland till this point is settled, since it may be that some of the results already obtained have been due to the fact that the extracts employed contained varying proportions of both substances.

CHLOROMA.

A STUDY OF THREE CASES OCCURRING IN CHILDREN WITH POST-MORTEM FINDINGS IN TWO CASES.

BY HUGH T. ASHBY, M.D. CAMB., F.R.C.P. LOND.,

VISITING PHYSICIAN FOR CHILDREN TO THE ROYAL MANCHESTER CHILDREN'S HOSPITAL;

AND

G. S. SMITH, M.B., CH.B. MANCH.,

FIRST ASSISTANT, CLINICAL LABORATORY, MANCHESTER ROYAL INFIRMARY.

CHLOROMA is a rare disease allied to leukæmia. Up to the end of the year 1926 about 150 cases had been recorded, not apparently some of these were proved beyond reasonable doubt to be chloromata.[1] The children here recorded were all males, aged 2½, 4, and 7 years respectively.

The characteristic feature of chloroma is the presence of firm tumour growths in connexion with the orbits, temporal fossæ, and periosteum of the bones of the skull, although they may occur in other places. Exophthalmos, with hæmorrhage into the upper and lower eyelids as the eyes become prominent, is also a striking sign which makes the disease readily recognisable. In the majority of cases there are firm diffuse bilateral swellings extending into the temporal fossæ; these are seen also on X ray examination of the skull. The growths were confined to the skull in the three cases recorded here, though the periosteum of the bones of the vertebral column, ribs, and sternum have been affected in some of the previously recorded cases.[1]

The tumours grow rapidly and the disease proves fatal in a few weeks. There is generally a peculiar greenish colour around the eyes during life, and other parts of the body are found to have the green colour at a post-mortem examination. One of the patients (Case 3) had the colour a few days before death, and it was also found in his growths. In the second case the green colour was seen quite clearly at the post-mortem, though it was not noticed before death. The green colour was not seen in

the third case and no post-mortem was allowed. The exact nature of the pigment is unknown, although it is thought to be an iron compound.[2]

The blood picture in recorded cases is stated to be sometimes that of lymphatic leukæmia and sometimes that of myelogenous leukæmia. It is significant, however, that nearly all the cases recently thoroughly examined have been thought to be myelogenous. Piney states that the blood is always myeloid in type.[3] The leucocytosis is not generally so marked as in cases of the typical leukæmias, but appears from the literature to be very variable, and in any one case the number of leucocytes in the blood may show enormous changes in relatively short periods of time. The lowest white count recorded is 3200 per c.mm.[4] and the highest 1,880,000 per c.mm.[5] There is a very marked anæmia.

The spleen was not increased in size in any of the three cases, but the liver was moderately enlarged. There was no actual loss of sight in any case, except perhaps in the last few days of life, when the cornea became ulcerated, with much conjunctivitis due to advanced proptosis. Each of two patients had a discharging ear, which started before the symptoms of chloroma became definite. There was no deafness. Headache, or at least pain in the eyes, was a marked and distressing symptom in each case and had to be relieved by hypnotics. There were no enlarged lymphatic glands and no purpuric spots in the skin. The reflexes were normal and there was no vomiting. All the patients wasted rapidly and died after an illness which lasted only a few weeks.

CASE 1.—A boy, aged 4 years, was admitted to hospital on Nov. 9th, 1927. He had had scarlet fever three months previously, followed by ear discharge. A month before admission he had had swelling of the eyes in the morning, which went down as the day progressed. He was then thought to have nephritis. Two weeks before admission to hospital swellings appeared over the eyes and he complained of headache. Apart from this he had been healthy.

Condition on Admission.—He was anæmic and thin. The skin was normal in colour. There was very marked exophthalmos, equal in both eyes. This gave him a most peculiar uncanny appearance, and, in fact, some of the other children in the ward were frightened of him. There was some conjunctivitis in the left eye. Directly above each eye there was a firm almond-shaped tumour, fixed to the frontal bone; it was these tumours which caused the proptosis. There was also a tumour growth in each temporal fossa. X ray examination of the skull showed some opacity behind the eyes. There was a discharge from the left ear. The heart, lungs, spleen, and urine were normal, though there was a hæmic murmur at the base of the heart. The liver was slightly enlarged. The reflexes were normal. The mouth was dirty and the tonsils enlarged. Dr. T. M. Bride examined the eyes, and reported that the discs were pale and that there were hæmorrhages into the retina on each side. There was no optic neuritis and the sight was good.

After admission to hospital the patient rapidly became worse and the headache more intense. The eyes began to bulge more as the tumour growths increased and became trophic, with much ecchymosis into the lids. The swellings in the temporal fossæ also increased in size.

The blood examination was as follows: Red blood corpuscles, 1,954,000 per c.mm.; leucocytes, 27,600 per c.mm.; hæmoglobin, 24 per cent.; colour-index, 0·6. The differential count (per cent.) was: Polymorphs, 17·6; lymphocytes, 78·6; large mononuclears, 2·4; eosinophils, 0; mast cells, 1·6. The red cells did not show anisocytosis or poikilocytosis. Blood-platelets were scanty. Unfortunately an oxidase reaction was not performed.

The child died on Nov. 26th after an illness of just over six weeks. No post-mortem was allowed.

CASE 2.—A boy, aged 2½ years, was admitted to hospital on Nov. 16th, 1927, a week later than the previous case. It is curious that two similar cases of such a rare disease should come for treatment within a week of each other. The previous history and family history were excellent. Six weeks before admission to hospital he began to have swelling of the eyelids, and at the same time a swelling was noticed in the left temporal fossa. The swelling over the eyes slowly increased and the eyes became prominent. There had been no œdema of the feet. The appetite was good and he had not lost much weight. He had, however, become pale, and complained of headache.

Condition on Admission.—He was very anæmic and there was a marked proptosis of the eyes, with congestion of the lids. Behind the upper eyelids there were firm, fixed almond-shaped swellings, and there were diffuse swellings in each temporal fossa. There was no discharge from the ears. The heart was normal and there was no œdema. The spleen could not be felt, but the liver was slightly enlarged. There were no enlarged glands. The urine was normal. Dr. Bride examined the eyes and reported that the fundi were normal. An X ray examination of the skull showed some opacity behind each orbit, but nothing else.

The patient became rapidly worse and the headache more severe. No green coloration was seen at any time. Death took place on Dec. 10th after an illness which had lasted about 10 weeks.

A report of the blood examination on Nov. 20th was as follows: Red blood corpuscles, 3,568,000 per c.mm.; leucocytes, 14,200 per c.mm.; hæmoglobin, 42 per cent.; colour-index, 0·6. Differential count (per cent.) (500): Polymorphonuclears, 27·2; lymphocytes, 70·4; large mononuclears, 2·4; eosinophils and mast cells, nil. There was no aniso- or poikilocytosis. Platelets were scanty. A film only was supplied on Dec. 8th, two days before death, and this gave a differential count (per cent.) (500): Polymorphonuclears, 6·6; lymphocytes, 31·0; large mononuclears, 2·0; eosinophils and mast cells, nil; neutrophil myelocytes, 2·2; myeloblasts, 58·2. The polymorphonuclear cells and lymphocytes (which were nearly all of the small variety) had normal appearances in the Leishman film. The cells, which have been classed as myeloblasts, were fairly large, non-granular, mononuclear cells with slightly basophilic cytoplasm, which varied in amount but was generally only a rim around the nucleus. In quite a number of these cells 3, 4 or 5 nucleoli could be seen. The red blood corpuscles showed slight poikilocytosis and well-marked anisocytosis; no nucleated red cells were seen. Platelets scanty.

Chloroma in a boy aged 4 years showing the marked exophthalmos.

As only one stained film was submitted for examination and the child died before others could be obtained, films were prepared from blood taken post mortem. The oxidase reaction, carried out according to Shaw Dunn's method, gave the following result (per cent.) (1000 counted): Positive reaction, 67·3; negative reaction, 32·7. The majority of the cells classed as positive gave a well-marked reaction and a few a faint reaction. This result, together with the appearance of the Leishman film, was considered sufficient evidence for classing the cells as myeloblasts. In the former count (done 3 weeks earlier) no oxidase reaction was carried out, and the mononuclear cells were all classed as lymphocytes.

Post-mortem Examination, Performed 24 Hours after Death.—There was a moderate degree of emaciation; no petechiæ. hæmorrhages were found on the skin. The head was abnormally large for a child of this age, and the eyes showed very marked proptosis with much ectropion of the lower eyelids and marked ulceration of the palpebral conjunctiva more advanced on the left side than on the right. There were no pleural adhesions and the pleura was free from petechial hæmorrhages. The right lung did not show any gross changes. The lower lobe of the left lung was consolidated, and on section showed patchy broncho-pneumonia. No petechial hæmorrhages could be detected in the pericardium, and there was no excess of free fluid. The heart was normal in size and there were no gross changes in the cardiac muscle or in the valves. The spleen was not enlarged and was of firm consistency; the Malpighian bodies stood out very distinctly. There was no perisplenitis. The liver did not appear to be enlarged. On section the mottling characteristic of early fatty degeneration due to congestion was seen. The kidneys did not exhibit any gross changes and were normal in size. The Peyer's patches and lymph glands did not show any abnormality.

Skull: When the orbital roofs were removed, a retro-orbital tumour was exposed on each side, stretching across

e whole width of the orbit and appearing as bands about 5 cm. in width and 0·5 cm. in thickness at the thickest rt. They had no connexion with the skull except at eir extremities where they were attached to periosteum. hen first exposed they were of a dark olive-green colour, t this changed to a dirty brown shortly after exposure. ese masses were hard and seemed very fibrous on section. trace of green coloration could be found in the marrow tween the diploe. The brain, which weighed 1600 grms., peared normal externally and there was no marked ttening of the convolutions. On section it showed multiple fuse hæmorrhages, chiefly in the white matter, most of the morrhages being of pin-head size and some being slightly ger. The meninges appeared normal and there was no n of hydrocephalus.

The right femur was uniformly filled throughout its whole gth with marrow of a dark olive-green colour. The our faded slightly after exposure, but still had a greenish t next day. No areas of hæmorrhage were seen in the rrow. The rib marrow was similar in appearance.

Histology.—The two retro-orbital tumours gave similar tological appearances. For the most part they consisted a dense fibrous stroma, of poor vascularity, containing a y non-granular mononuclear cells of medium size with y varying amounts of cytoplasm. In fact, the appear-ce under the low power of the microscope was similar to t of granulation tissue, but in two distinct areas the rous stroma was diminished and the tissue was highly lular. These cells were similar in appearance to those n in sections of the bone-marrow, and had nuclear staining h as is found in myeloblasts. Portions of nerves were nd in the sections of the tumour, and at one part the nour cells had infiltrated muscle-fibres. Many of the ls scattered throughout the stroma gave a faint positive dase reaction, and practically all those in the more lular portions of the tumour were positive, about 50 per t. strongly and 50 per cent. more weakly.

Marrow : Sections of the marrow showed the fat cells to few in number. The tissue was almost entirely composed non-granular mononuclear cells lying in a light reticulum. e cells varied a fair amount in size and in the amount of oplasm. Most of these cells were considered to be eloblasts. Films of fresh marrow stained by Leishman's thod showed few eosinophil and basophil myelocytes. e red blood corpuscles were scattered sparsely throughout marrow, and normoblasts were scarce. No megalo-yocytes could be seen. Wet fixed films of marrow rrosive alcohol) stained by hæmalum and eosin showed fine fibrillar character of the nuclei of the predominating nonuclear cells. The oxidase reaction was faintly itive for the majority of cells, but the reaction was not so rked or so diffuse as in the leukæmic cells in other organs.

Spleen : The capsule appeared to be stretched ; the lymph icles were numerous and showed up well, but the central sel was often thickened and sometimes almost occluded. e pulp contained a mixture of roughly equal numbers of corpuscles and mononuclear cells similar to those seen he bone-marrow. In mercury-fixed preparations stained eosin and methylene-blue, these cells were larger than the ghbouring lymphocytes in the follicles and did not stain rly so deeply. A few normoblasts were seen in the pulp. the oxidase method the unstained lymph follicles stood in marked contrast to the pulp-cells, the majority of ch were strongly positive.

Liver : The portal tracts showed small collections of nonuclear cells, and there were very small groups of se cells scattered about in the dilated capillaries. Central gestion was very marked, with large numbers of red puscles and a few mononuclear cells lying around the r cells, which were undergoing fatty degeneration. The dase reaction was positive for the mononuclear cells.

Brain : Sections of the brain showed a large number of all hæmorrhages. Some of these were merely collections ed blood corpuscles, but many consisted of a small dense ection of mononuclear cells, around which was a ring of corpuscles several layers in thickness. It seems probable these were leukæmic infiltrations with surrounding morrhage. The cells in the centre of these infiltrations e a strongly positive oxidase reaction.

Kidney : A small amount of congestion was noted, but no ection of white cells. The oxidase reaction was slightly itive in a few of the cells in the glomeruli and in occasional s in the connective tissue.

Heart : Nothing abnormal was detected.

Lung : Sections of the lower lobe of the left lung showed nsive broncho-pneumonia. The capillaries were much ted, and hæmorrhages were present in many parts. alveolar walls were very thickened and the type of was chiefly mononuclear, although polymorphonuclear ocytes were also present in fair numbers. A large mber of the cells in the consolidated portion were oxidase-itive. Films of the tissues stained by the ferrocyanide hod showed a very small amount of free iron in a few of the liver cells and a larger amount in the spleen. The reaction for the other tissues gave no result.

CASE 3.—A boy, aged 7 years, was seen and observed in September, 1922. A full report of this case with the post-mortem findings by Dr. A. Sellers has been published in THE LANCET.[7] This case was very similar to the previous two cases. The green colour was seen in the eyes before death and the tumour growths were found to be greenish at the post-mortem.

We desire to thank Dr. T. H. Oliver for obtaining permission for the post-mortem examination in the second case, and also Dr. A. E. Somerford and Dr. W. Susman for their help.

Clinical and Laboratory Notes.

A CASE OF SPLENIC ANÆMIA DUE TO A STREPTOTHRIX ORGANISM.

BY JOHN FAWCETT, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL;
AND
A. G. GIBSON, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY AND READER IN MORBID ANATOMY IN THE UNIVERSITY OF OXFORD.

WITHIN the last two years considerable interest has been reawakened in the mycotic hypothesis of the origin of splenic anæmia and Banti's disease first put forward by one of us in 1913.[3] Nanta and Pinoy [4] in 1926 described certain cases of Algerian splenomegaly as due to a variety of aspergillus to which they gave the name *Sterigmatocystis nidulans*. Weil, Gregoire, and Flandrin [5] in 1927, amongst 16 cases of splenomegaly in Paris, found seven which they ascribed to a mycotic cause and in two of these they were able to obtain a culture of an aspergillus. A discussion on the subject is reported in the *Presse Médicale* for Oct. 26th, 1927, and Askanazy and Schweitzer [6] described in 1927 a case they had observed in 1911.

It has therefore been thought desirable to bring forward this case, even though the pathogenicity of the organism has not been confirmed upon a second animal. The result corresponds in all respects to the animal experiments conducted by one of us with another organism, and coincided with a series of experiments with similar organisms on other monkeys with proper controls. The effect on the health of the animals was clearly interfered with in each case. The animal used for the present experiment suffered from tuberculosis as a terminal infection, for diarrhœa, which is almost invariable in this disease, was absent until August, 1924, when it is to be feared that it may have got access to infected food ; it was following this that the spleen was found to be very much larger than before. In a previous series [2] of experiments with three monkeys (*Macacus rhesus*) all succumbed within a few weeks of the injection to generalised tuberculosis.

The Case Described.

A girl of 11 was first admitted to Guy's Hospital under the care of one of us (J. F.) in November, 1913. Six weeks previously she had vomited after an attack of fainting, and three weeks later she was stated to have had three attacks of hæmatemesis. During this period there was continued

pyrexia. The only relevant item in the previous history was that there had been otitis media after an attack of measles at 4 years of age.

Condition on Admission.—She was anæmic and very ill. The blood count was as follows: red cells, 2,050,000; white cells, 18,750; hæmoglobin, 19 per cent.; colour-index, 0·42; differential count: neutrophils, 70 per cent.; lymphocytes, 29 per cent.; mast cells, 0·5 per cent.; normoblasts, 0·5 per cent. The spleen was much enlarged, reaching nearly to the level of the umbilicus, and ascites rapidly developed and required paracentesis, when a chylous fluid of sp. gr. 1011 was withdrawn; it contained cholesterol and globulin, but no cells.

Throughout this part of the patient's stay in hospital and for the next two months pyrexia continued. The fluid in the abdominal cavity reaccumulated but disappeared again. In January, 1914, a discharge from the left ear, which had been present intermittently since the age of 4 years, became worse, with suppuration in the mastoid, for which operation became necessary. The day after the operation severe hæmatemesis recurred and again on the two following days, and the patient became very ill. The *Bacillus diphtheriæ* was detected in the nasal discharge. Pyrexia persisted till the middle of March, 1914, after which it gradually subsided and the patient was discharged from hospital in the middle of May. At this time the red cells were estimated at 5,512,000 c.mm.

The patient was readmitted into Guy's Hospital in December, 1921. She was now 19 years of age and had been at work regularly since leaving the hospital in 1914, and without any illness until the day before admission when, after an attack of coughing, she vomited a large quantity of blood and passed blood in the stools on the following day. She had been married recently and was about three months pregnant. She was pale, and the blood count was: red cells, 3,200,000; white cells, 5320; hæmoglobin, 34 per cent. The spleen was large, smooth, and hard, and extended to just below the level of the umbilicus. Apart from a hæmic cardiac murmur no other abnormal physical signs were found on examination. The fragility of the red cells was normal, and the Wassermann reaction negative. By Jan. 3rd, 1922, the red cells had risen to 4,000,000 and the hæmoglobin to 54 per cent., and, by the end of the month, to 69 per cent. On Feb. 6th the blood count was as follows: red cells, 3,900,000; white cells, 6200; hæmoglobin, 78 per cent.; colour-index, 0·9. Differential count: neutrophils, 65 per cent.; lymphocytes, 30 per cent.; hyalines, 5 per cent. Early in March she had another hæmatemesis and the hæmoglobin dropped to 42 per cent. On March 7th Sir Alfred Fripp removed the spleen, which was free from adhesions except for a few at the upper pole which were easily dealt with. She recovered well from the operation and left the hospital in April, 1922. There is no record of the presence of cirrhosis of the liver, nor of the weight of the spleen after removal.

After leaving hospital in 1922 she progressed well until the early part of 1927, when hæmatemesis recurred on two or three occasions, but by March of that year she appeared to be in good health and her hæmoglobin content was about 70 per cent. of the normal.

Remarks on the Clinical Condition.

The case is given the title of "splenic anæmia" in that it belonged to the group of very chronic enlargements of the spleen with "secondary anæmia" for which no cause could be found. It seems possible, in view of the ascites which appeared in 1913, but which did not recur, that some cirrhotic change might already have been present in the liver. There was no evidence of peritonitis at that time; nor later, at the time of the operation, was any cause discovered to account for the ascites. If this suggestion is correct it is of interest to recognise the "latency" of the cirrhotic state from 1913 to 1921 and again after the splenectomy for a period of five years, and that even now there is, clinically, no evidence of cirrhosis of the liver. It is well recognised that the condition of the liver is one of the most variable features of splenic anæmia, and unless there are gross signs it is not possible to determine the presence of cirrhosis clinically. Another important feature is the recurrence of the hæmorrhage five years after the splenectomy, a rare but not unknown event, the possibility of which must not be forgotten in making a prognosis. However, as 15 years have passed since the condition was first recognised, it is quite possible that a quiescent state may yet ensue in our patient, the cirrhotic change, if present, being within such limits that the remainder of the liver tissue is sound enough to allow the viscus to function, and so to maintain a level of fair general health.

Pathological Investigation.

About one-half of the spleen was despatched to Oxford packed in a sterile towel and received by one of us (A. G. G.) on March 8th, the day after the operation.

The shape was preserved and externally there was recent perisplenitis. There were several deep congenital fissures. On section the spleen was mottled, Malpighian bodies were present, the pulp was firm and trabeculæ were seen in increased numbers. Here and there minute pigmented scars could be seen.

Microscopically the whole substance of the spleen, both pulp and trabeculæ, was more fibrous than normal, and the trabeculæ were thick. Malpighian bodies were of loose texture, and the central artery was thickened. The pigmented scars were similar to those that have been described previously, and which are referred to in continental literature as the nodules of Gandy-Gamna. They had a well-defined outline and consisted of a felted network, much of which was impregnated with iron. This network was here and there aggregated into bundles, some of which had a glistening hyaline appearance. Some of the nodules had a hæmorrhagic zone surrounding them. Under the oil immersion objective hæmotoxylin-stained threads of varying thickness could be detected in the periphery on careful search. Some of these showed true branching. Here and there were clear interruptions in their course, and long rod-like forms could also be detected. Anatomically these appearances conformed to the morphology of a streptothrix organism. There was no appearance suggestive of the spore head of an aspergillus but there were circular forms varying in size from that of a coccus to somewhat larger. There was a moderate degree of endophlebitis.

On March 8th 24 cultures of the pigmented points in the trabeculæ were made in serum broth. On the 9th there was no obvious contamination. On March 20th, 12 days after inoculation, two tubes showed a few streptococcal forms. These forms have been observed on several occasions in splenicultures, but on no occasion has it been possible to isolate an ordinary streptococcal growth in subculture. After 24 days one tube was found to show minute snowball like growths in the bottom of the tube, the medium being clear above. This was found to be a streptothrix with true branching, easily subcultured on agar and broth. Contamination appeared in two tubes after four weeks, but no other tube showed any streptothrix growths. The organism grew vigorously and conformed both morphologically and culturally with that described by one of us.[1]

Animal Experiment.

This type of streptothrix organism, when previously isolated from splenic culture, has been found to be pathogenic to monkeys only.[2]

A male adult bonnet monkey (*Macacus sinicus*), therefore of estimated age about 7 to 8 years, in very good condition, tame, and weighing 613 g., was used for the experiment. It was observed for four weeks before injection; there was

nothing abnormal to be felt in the abdomen, although the kidney on the left side was palpable. There was no tenderness in any part. Blood counts were done on three occasions and the hæmoglobin and red count increased slightly during the month. On Nov. 8th, 1923, the abdomen being found normal, 1 c.cm. of an emulsion in saline of a three-day sloped agar culture of the organism was injected intraperitoneally. There was a little restlessness for half an hour after the injection. The animal was found to be normal on Nov 9th and 16th. On the 23rd, 15 days after the injection, there was a slight flexion of the toes at the first tarsal joint which had not been noticed before, and there was doubtful abdominal discomfort on palpation. The appetite was very good. On Dec. 17th there was distinct abdominal tenderness on the left side. The spleen was felt, short and stumpy, and the kidney was tender. The gait was, if anything, slightly cramped, but strength, appetite, and coat were good. The blood culture on Dec. 31st was negative. On Jan. 31st, 1924, the spleen was again felt as a hard organ, and it was noticed that the animal yawned frequently. A second emulsion of a five-day culture of the organism was injected intraperitoneally. On Feb. 29th the spleen again felt hard and tender, and the blood culture on this date was again negative. On March 26th the spleen was easily felt and the animal was pale; the blood culture was again negative. On May 8th, 1924, the animal was pale, but strong and eating well. Nothing could be felt in the abdomen, but resistance was marked. Movements were not so active. The third injection of the organism intraperitoneally was made; there were no ill-effects next day. On June 12th it was noted that the animal was pale and going downhill. Movements were more deliberate when climbing, and the spleen was felt to be enlarged. The blood culture was again negative, though in three tubes long bacillary forms could be seen microscopically. On June 26th the animal was seen to sit more and there was less spring in his movements. The appetite was good.

During August, 1924, owing to the holiday, there was unavoidably some change in the care given to the feeding. On Sept. 4th the animal's coat was poor. There had been some diarrhœa and the spleen was easily felt, solid and tender. The weight, which had been 653 g. at the end of July, was 571 g. on Sept. 2nd. On Sept. 22nd another blood culture was taken. In one out of six tubes inoculated there was found, 29 days later, a growth of streptothrix of the same type as that injected. After that date the animal became increasingly pale and hypernœa on exertion was marked. The spleen was enlarged, easily felt, thick, and tender. Some diarrhœa was noticed, but the appetite continued good until a few days before it was killed on Nov. 10th, 1924. The post-mortem examination showed advanced tuberculosis with large caseous masses in the omentum, spleen, and lungs and posterior mediastinal glands, and a few scattered foci in the liver. Microscopically the presence of tubercle bacilli was confirmed, though they were not isolated in culture.

Summary.—Gradual decline in health followed intraperitoneal injections of the streptothrix organism, together with enlargement of the spleen, persistence of appetite, and tenderness of the abdomen. There was a terminal infection with the tubercle bacillus.

On the facts here described—the isolation of the organism, its pathogenicity to a monkey, and re-isolation by blood culture from the animal—we submit that Koch's postulates have been fulfilled and that the streptothrix organism is the cause of the disease. The organism was submitted to Sir Aldo Castellani, who regarded it as a species of nocardia.

A METHOD OF TREATING LUPUS VULGARIS.

By A. R. Somerford, M.B., Ch.B. Manch.,

ASSISTANT MEDICAL OFFICER, MANCHESTER ROYAL INFIRMARY
LATE HOUSE SURGEON, MANCHESTER AND SALFORD SKIN HOSPITAL.

The treatment of lupus vulgaris aims at the eradication of the disease with the production of a supple unnoticeable cicatrix. Numerous methods have been employed with varying degree of success. During the last 18 months, with the permission of the honorary medical staff of the Manchester and Salford Hospital for Skin Diseases, I have employed a treatment which has been so satisfactory that publication seems to be justified.

Method.

The skin over the diseased area is washed with soap and water and any fatty material is removed by swabbing with methylated spirit. The whole area, or a portion of it if the whole is large, is painted with the liquor hydrargyri nitratis acidus. This is best applied by wrapping a little cotton-wool round the end of a match and soaking it in the acid, which is rubbed well into the diseased tissue until coagulation occurs, when the tissues become grey. This process may be rather painful, and in nervous patients it may be advisable to paint the area previously with a solution of novocaine. The painted area is then covered with lint spread with the following ointment:—

℞ Ac. carbol., ℥ xv.; ung. zinc., ℥i.

The dressing is made air-tight by overlapping pieces of surgical strapping and completed by a pad of wool and a bandage. This is left in position for 48 hours, and on removal ulceration, with some pus formation, is found to have taken place. In many cases one application is sufficient, but the process may be repeated any number of times. When ulceration has proceeded deeply enough the dressing is replaced by lint spread with Brooke's ointment:—

℞ Ung. hyd. oleat., 10 per cent. (B.P. 1885), ℥ii.; acid. salicyl., grs. xv.; ichthyol., ℥xv.; zinc oxid., ℥iss; amyli, ℥iss; paraffin. moll., ad. ℥i.

When the area has completely healed it will be possible to see if any tuberculous tissue remains, in which case the areas still diseased can be re-treated.

Results.

In actual practice I have found that two applications usually transform a tuberculous plaque into a supple scar with a few nodules at the periphery which can readily be dealt with. This is illustrated in the following cases:—

Case 1.—A youth, aged 23, had suffered from lupus vulgaris of the neck for many years. It had been treated by X ray therapy which had left a mottled and unsightly cicatrix. The upper edge had relapsed with the formation of a raised plaque of tuberculous tissue about the size of a florin, showing typical apple jelly nodules. A month after treatment by one application of the above method, the tuberculous area was replaced by a supple cicatrix which was slightly erythematous but not depressed below the level of the surrounding skin, and evidence of tuberculosis was not present. I saw the patient again one year after treatment and the scar was still healthy and almost unnoticeable.

Case 2.—A woman had a plaque of lupus on the left cheek; the nodules were raised above the surrounding skin and had become confluent. After treatment the area was ulcerated but not very deeply, so the treatment was repeated and then the area was allowed to heal. The mass of tuberculous tissue was replaced by a whitish supple scar in which were embedded discrete apple jelly nodules which were subsequently dealt with by spiking with the liquor hydrargyri nitratis acidus.

I have also used this method to ulcerate the skin before applying powdered potassium permanganate crystals: the crystals are applied directly to the ulcerated surface and then moistened with cold water. This gave a good result in one case in which all previous treatment had proved useless.

The advantages of this treatment are: (1) it is easily performed in an out-patient department; (2) it is inexpensive and usually causes very little pain; (3) the cosmetic result is good; (4) the disease is efficiently treated and recurrences are less frequent than when the disease is treated by erasion.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF LARYNGOLOGY AND OTOLOGY.

THE joint summer meeting of these Sections was held in London from May 31st to June 2nd. At the first session Mr. J. F. O'MALLEY took the chair, and a paper on

Achalasia and Degeneration of Auerbach's Plexus

was read by Mr. A. T. RAKE. The plexus, he said, was really a cell station for the vagus nerve-fibres. These nerve-fibres ran to the plexus, whence new fibres passed to the muscle-fibres. The function of the vagal supply was the two-fold one of preserving the normal œsophageal tone and supplying the cardiac sphincter; it caused relaxation of the sphincter preceding the normal peristaltic wave which took the food into the stomach. Therefore any lesion of the vagal nerve-fibres would upset this relaxation of the cardia which must take place before food could reach the stomach. Lesions might be proximal to Auerbach's plexus, or in the plexus, or distal to it. In some achalasic cases the plexus was found to be about twice its normal size, the whole of it being infiltrated with small round cells. In addition there were multiple vessels not seen in the normal Auerbach's plexus. In the chronic stage there were around the fibrous plexus large blood-vessels with thickened walls; the appearance was, indeed, so typical that it had been suggested that change was primarily vascular. Mr. Rake, however, was strongly of opinion that the change was primarily inflammatory. In none of the many sections which he had examined were there any ganglion cells.

The chairman (Mr. O'MALLEY), said that Dr. Brown Kelly, when he lectured on the subject last year, had not committed himself beyond saying it was a neuropathic change which occurred in this condition; but the present communication carried the matter a step further. "Cardio-fibrositis" seemed a better name for the condition.

Dr. A. F. HURST said it had occurred to him, 15 years ago, that spasm did not constitute an adequate explanation of achalasia. In some of the cases hypertrophy of the cardiac sphincter was found, but not in all; and he thought that the condition was parallel to Hirschsprung's disease in the intestine, in which there was absence of the normal relaxation of the sphincter. Years ago he had suggested that some organic change would be found in Auerbach's plexus in these cases.

Dr. A. BROWN KELLY considered that Mr. Rake was the first to describe fibrotic changes as a cause of destruction of nerve-cells in the plexus, but Dr. Munro Cameron had demonstrated these changes in cases of cardiospasm. The case upon which Mr. Rake's paper was based appeared to be rather one of hypertrophy of the wall of the œsophagus, but without dilatation; the patient had not had any symptoms of cardiospasm. Dr. Kelly's own view was that the degenerative changes in Auerbach's plexus gave rise to incoördination of the myotonic reflex in the affected region, that in consequence of the involvement of nerve-cells and their connexions the transmission of stimuli was interrupted, so that they might not reach the distant longitudinal layer. Hence the latter might remain inactive while the circular layer contracted.

Mr. W. STUART-LOW had found that many disabilities due to such conditions yielded to the use of warm olive oil as a lubricant to the œsophagus.

Mr. W. M. MOLLISON read a paper on

Dysphagia due to Pharyngeal Paralysis.

Patients often presented themselves, he said, because of difficulty in swallowing, but it was not common for this to be due to paralysis of the pharyngeal wall. Yet in the last few years he had seen several such cases. Unfortunately the symptom could not be treated with much chance of success. Complete unilateral paralysis of the vagus caused unilateral paralysis of palate, pharynx, and larynx, but there was only slight interference with swallowing. When laryngeal paralysis was complete, the cord was flaccid, both adductors and abductors being paralysed. It was possible to imagine a small hæmorrhage occurring in the middle of the nucleus ambiguus which would damage the fibres to the pharyngeal plexus, and as the effects of the bleeding became localised, the effect might be restricted to the palate, or the pharynx or larynx. Causes of pharyngeal paralysis could be classified into: (*a*) central; (*b*) intracranial; (*c*) extracranial; (*d*) peripheral (as from diphtheria or lead poisoning). The prognosis in the condition when due to diphtheria was favourable, but it was serious when the disability was due to progressive muscular atrophy and amyotrophic lateral sclerosis; it was somewhat better in acute bulbar paralysis. Mr. Mollison gave details of the cases he had seen, including two in which the lesion was at the base of the skull (one from a bullet wound, the other from tuberculous glands). A great difficulty in all the cases was that the patient was unable to get rid of his saliva. Cases of the kind were not infrequently diagnosed as whooping-cough. Five of the six cases recovered, apparently permanently.

Dr. LOWNDES YATES read a paper on

Post-operative Hœmorrhage.

The title of the paper was "methods of estimating the liability to post-operative hæmorrhage from unsutured wounds." It was based upon cases in his experience in which hæmorrhages had occurred after tonsillectomy, though he had ligatured every bleeding point. In two of them the patients gave a history of spontaneous epistaxis. In one case of epistaxis he noticed that the blood from the nose did not appear to clot. He found that in three-fifths of the cases of spontaneous epistaxis the clotting-time was prolonged—i.e., it was from 6 to 50 minutes. Calcium did not reduce this time. To one of the patients having acidosis he gave sodium bicarbonate, and the clotting-time thereafter returned to the normal. Cases of epistaxis were similarly benefited as soon as the sodium bicarbonate had rendered the urine alkaline. Liability to hæmorrhage recurred about a month after the administration of the sodium bicarbonate was stopped. Clotting was brought to the normal also by dealing with a focal sepsis when such existed. He next investigated cases with a toxic focus but whose blood-clotting-time was normal. Some had a highly acid urine which took a long time to become alkaline when sodium bicarbonate was given. It was thus clear that the alteration in the clotting-time did not depend on the presence of every type of compensated acidosis, only on some special type. His surmise was that the organisms in a toxic focus, when they led to acidosis, elaborated acid products which had a greater affinity for some bases than for others, and that when an acid was elaborated which had a great affinity for calcium, it combined with the calcium of the blood all of which was no longer available for activating fibrin ferment. Knowledge on these points had enabled him to escape trouble due to post-operative hæmorrhage. The simple clinical method he followed was to put on a slide a drop of blood from the ear. On clotting, the blood ceased to run down the slide, which was then moved into a vertical position. When the blood was clotted the ear was again examined to see if the pin-prick was still bleeding. Cases in which the clotting-time was prolonged before the operation and caused excessive hæmorrhage during its performance had a tendency to secondary hæmorrhage afterwards. In this class there was a compensated acidosis, and if this was recognised and remedied before the operation, the liability to hæmorrhage in these cases was apparently removed. In many cases of secondary hæmorrhage it

as the clotting-time, not the surgeon, which was at ault. When the clotting-time was long it was difficult o see which were the bleeding vessels, as the whole rea appeared to be oozing; but sprinkling a finely ivided powder, such as bismuth, would cause a leeding artery to stand out red on the whitened rface.

The CHAIRMAN said that for a number of years e had been in the habit of giving patients, especially ildren, some alkali three or four days before operation nd until about three days afterwards. He had the lea that it was good from the point of acidosis and iat of hæmorrhage. Post-operative hæmorrhage emed more common when chloroform was the næsthetic than when ether or nitrous oxide was sed. Crile's view was that it was because the blood ressure was depressed by chloroform.

On the afternoon of May 31st the Sections met nder the chairmanship of Mr. HAROLD BARWELL.

A paper was read by Mr. A. J. WRIGHT (Bristol) on

The Signification of Silent Tracheotomy.

It was based upon two surgical accidents, one of hich was the following. Eight years ago, in connexion ith an operation for submucous resection, he pplied a finger of a rubber glove filled with gauze. he patient was found not to be breathing, and on the duction of artificial respiration no air was entering. he plugs were found to be missing from the nose. racheotomy was carried out and artificial respiration sumed. One of the two plugs was extracted from ie bifurcation of the trachea, and the patient covered. In neither of the two cases was there ough, nor were there obvious signs of asphyxia, ough cyanosis occurred and tended to increase. he whole picture was that of an overdose of nasthetic, but a significant difference was that there as no sound of any air entering the lungs; also, n opening the trachea, instead of the usual explosive ish of air, there was silence. The cases showed that lockage of the bifurcation of the trachea by a foreign dy did not necessarily produce obvious signs of sphyxia. Some of the deaths which had been scribed to the anæsthetic might have been due to ich an accident as he had related.

The paper was discussed by Mr. MOLLISON, Mr. USGRAVE WOODMAN and Mr. M. VLASTO.

Dr. P. WATSON-WILLIAMS read a paper on

Familial Infectivity of Chronic Sinusitis.

e laid stress on the importance of bearing in mind iat members of some families had an inborn predis- osition to catarrhal infections. A child, when the ubject of chronic nasal sinus infection, rarely escaped fection of tonsils and adenoids, and when these ad been removed the persistent re-infection of the maining lymphoid tissue caused recurrent symptoms, nd the child would infect brothers and sisters, even ough relative immunity might be conferred by uto-immunisation. Dr. Watson-Williams showed the isease records of several families to support his ntention, the list of disabilities including cholecystitis nd appendicitis. The diagnosis of a "common cold" ften covered a serious condition.

Mr. STUART-LOW drew attention to the importance damp marshy localities in causing and maintaining ronic catarrhal infections. Mr. MUSGRAVE WOODMAN aid the possibility of the nurse infecting the children ould always be enquired into. Dr. J. S. FRASER voured the idea that some people had what could e termed a catarrhal diathesis.

Sir STCLAIR THOMSON read a paper on

ntrinsic Cancer of the Larynx Operated through a Laryngo-fissure.

e said he had recently completed a series of 70 cases f laryngo-fissure for intrinsic cancer of the larynx, part from those in which he had followed this route o treat enchondroma or for exploration. He had btained the after-history of each of the 70 cases. The series extended over 28 years, as the disease, compared with malignant disease elsewhere, such as of the breast, was very rare. His object in these cases now was to go as far down into the subglottic space as possible and up on to the ventricular band and to remove everything between those points, including the internal perichondrium, leaving only the external perichondrium. The dangerous area was the subglottic space, and he liked to get away not only the anterior commissure, but a little tissue to the other side of it.

Laryngo-fissure gave an excellent result. Sixty cases were private ones, 10 were hospital patients. In females the disease occurred earlier in life than in men, but in men its onset continued later. Of the 70 patients, 34 were still alive 3 to 19 years after operation. There had been 18 deaths from causes other than recurrence and 3 deaths from operation—namely, 1 from rupture of œsophagus due to vomiting, and 2 from bleeding; these two patients would probably not have died if they had not been given heroin or morphia. He never used "dope" drugs, either before or after operation. Eleven of the patients had developed malignant disease elsewhere, including glands in the neck. Most of the recurrences were within the first year, showing the importance of Semon's instructions to patients to present themselves once monthly for the first year. In borderline cases, should there be recurrence, laryngectomy should be done. In subglottic cases, those in which the cord was fixed, the prognosis was unfavourable. Sir StClair considered that there should be no operative death in these cases unless something exceptional occurred. The operation left the patient with an adequate voice and no social disability, and in selected cases the cure should be lasting. He had in the past operated upon cases such as, with a larger experience, he would not attempt now. Of nine cases in which the cord was fixed, only four lived more than three years after operation. He alluded to the importance of a careful preparation of the patient. He was not insistent upon any particular form of anæsthesia; the operation could be done under local anæsthesia, and if a general anæsthetic was preferred, the patient should not be under it very deeply. No atropine, morphia, or similar drugs should on any account be used, but bromide or aspirin was permissible. He did not see any advantage in using cocaine beforehand, nor in plugging the larynx, nor in doing endoresections. There was still need to urge that these cases should be sent to the laryngologist at an earlier stage, for that was, naturally, the stage at which operation gave the best results.

The paper was discussed by the President, Prof. E. PORTMANN, Dr. J. B. PACKARD (Philadelphia), Mr. STUART-LOW, Mr. THACKER NEVILLE, Dr. CAVENAGH (Worcester) and Dr. J. S. FRASER. Sir STCLAIR THOMSON replied.

The meeting on June 1st was devoted to otology, and the chair was occupied by the President of the Otological Section, Dr. J. S. FRASER. Two papers were read on otosclerosis. The first was by Dr. A. LOWNDES YATES, and was entitled

A Working Hypothesis for Research in Otosclerosis.

In attempting to investigate the ætiology of chronic progressive deafness, he had concluded that it was necessary to follow two lines of work: to establish a system of quantitative testing of the hearing which could be expressed in graphic form, and the estimation in this way of the various forms of deafness. Hartmann's work proved that if otosclerosis affected the cochlear nerve there was a progressive increase in the power of hearing as one passed down the auditory scale, while the reverse was the case if the stapedio-vestibular junction was affected. Cases of clinical otosclerosis Dr. Yates considered to be those in which Bezold's triad symptom-complex was present, with a patent Eustachian tube and no demonstrable adhesive process in the middle ear or

of a former perforation of the membrane. He exhibited and demonstrated various graphs, and said there were, from the standpoint of audiography, three types of aural disease: (1) nerve or internal ear deafness; (2) otitis media with indrawn membrane and limitation of its movements by adhesion to promontory; (3) acute otitis media, subacute otitis media and otosclerosis, in which there was a progressively increasing departure from the graph.

Prof. OTTO MAYER (Vienna), the recipient of the Dalby Memorial Prize, spoke on

Pathology of Otosclerosis.

By means of a series of specimens he showed that in this disease the original bone of the labyrinth capsule became absorbed and bone-marrow was formed in which an excessive number of osteoblasts abounded. Thus there was formed new bone which was of imperfect character. The marrow spaces could be found occupied by large vessels. This new bone overgrew the oval window and the round window. The lesions in otosclerosis were multiple, and the multiple fibromata in other parts of the system must be regarded as manifestations of the same tendency. He had found present in these cases a synchondrosis, and also bony growths in the petrous bone, represented by exostosis on its posterior aspect. Among 50 cases of deaf-mutism which he had examined he found typical areas of otosclerosis in 20 per cent. In 15 out of 30 cases of otosclerosis he had found some mal-development of the inner ear, and anomalies of the cochlear frame-work. That otosclerosis was a hereditary disease was supported by the conditions found in the inner ear on pathological investigation. Indeed the disease affected the whole auditory apparatus, which showed a general tendency towards malformation. He felt convinced that the disease was not inflammatory; and was equally sure that it involved connective tissue and bone—was, indeed, a hyperplasia.

Dr. A. A. GRAY expressed his agreement with nearly everything Prof. Mayer said, and said his own view, based on a considerable study of the subject, was that the disease could only occur in a person who had a personal tendency or idiosyncracy towards the disease, though he did not think it was found to be hereditary in every case. In some instances bone was deposited in excess, while in others there was only absorption of bone. It was not only a disease of bone. He thought not only temporal bones should be investigated in inquiring further into this question, but also the brain.

Mr. G. J. JENKINS spoke of the supposed association of the disease with osteitis deformans, remarking that in the five cases of the latter disease which he had submitted to microscopical examination he had not found any of the bony changes which were characteristic of otosclerosis, from which he concluded that they were different diseases. He did not regard otosclerosis as atavistic; it was a progressive condition, and atavism was never progressive.

Mr. SOMERVILLE HASTINGS considered that Prof. Mayer's work on this subject was beyond all praise. He (the speaker) had seen cases of what he would describe clinically as middle-ear deafness change into typical otosclerosis. There was a tendency to conclude that because in the latter no active changes were detected, and no septic focus could be found in nose or nasopharynx, no such lesion had ever been present, the fact being that a process which was started by an inflammation might persist after the cause was removed.

Mr. JAMES ADAM (Glasgow) mentioned a family whose members had a formidable galaxy of diseases and disabilities, various suppurative conditions, atheromatous arteries, scoliosis, kyphosis of the spine, and fragilitas ossium.

Sir JAMES DUNDAS-GRANT expressed the hope that the diagnosis of otosclerosis would not be made rashly, as it was regarded by many as almost the equivalent of a death-warrant. He had, however, seen the condition become stationary in some, while a few got somewhat better. He favoured supplying patients with a Pollitzerizing apparatus for self-use with a chloroform vapour.

The PRESIDENT showed a series of microscopical slides from cases of otosclerosis, under high magnification, to support his contention that it was a chronic inflammatory affection. He carefully indicated the areas in which, he submitted, the bone was inflamed.

Prof. MAYER and Dr. YATES replied.

Dr. HAROLD KISCH demonstrated by slides and described a method employed by him in grafting with temporal muscle after the radical mastoid operation had left a large open cavity. The use of this muscle enabled the graft to remain attached to its parent until it grew in the new situation.

Dr. DOUGLAS GUTHRIE described a method of fat-grafting in mastoid surgery, which he used for children under 8 years of age. The results were very encouraging, for he had 23 cases of healing by first intention out of 28 cases last year.

Many members discussed these two communications, and Friday afternoon was devoted to the inspection of 16 clinical cases.

The Saturday morning session on Otology, with Dr. FRASER in the chair, was opened by Prof. G. PORTMANN (Bordeaux), who read a paper on

Vasomotor Affections of the Internal Ear.

Vasomotor disturbances, he said, could be regarded as some of the most important and pathognomonic elements in internal ear affections; they depended directly on the sympathetic system. Recently, in association with colleagues, he had experimented on the action of the sympathetic in reference to the labyrinth, the experiments consisting of either pericarotid sympathectomy or the injection of vasomotor drugs, and compression of vertebral and common carotid arteries, and the warm bath test. For a long time otologists had been impressed by the action of the sympathetic on the labyrinthine circulation on the one hand, and on the other by the secretion of the endolymphatic fluid. Having observed a typical angiospasm of the anterior labyrinth in a patient with Reynaud's disease, Lermoyez had drawn attention to the similar structure of the two situations (the digital and the labyrinthine) and summed up a particular labyrinthine affection as "the vertigo which makes one hear"; it appeared to be a spasm of the internal auditory artery. Prof. Portmann submitted the following comparative table of the two conditions:—

Ménière's Disease.	*Lermoyez's Syndrome.*
Good hearing.	Good hearing.
Sudden vertigo.	Gradual deafness.
Sudden and decreasing deafness.	Sudden vertigo.
Slow recovery.	Quick return of hearing.

Angiospasm could well explain the onset of vertigo and the disappearance of the deafness, both depending on the removal of the barrier of the labyrinthine artery. The pathogeny of Ménière's disease was still debatable; Ménière's own view was that it was caused by intra-labyrinthine hæmorrhage, while all who had tried to solve it gave an important place in causation to vasomotor troubles. Many facts pointed to vertigo being essentially a phenomenon of irritation; vertigo disappeared with destruction of the labyrinth, and irritation of the internal membranous ear or of the vestibular nerve was required to produce a giddy sensation. A strident noise by irritating the original filaments of the cochlear nerve might also cause vertigo reflexly through vaso-dilatation. How, Prof. Portmann asked, was this irritation of the vestibular nerve produced? No satisfactory answer could yet be to this question, but whatever the mechanism Ménière's disease was closely connected with vasomotor phenomena and therefore with the sympathetic equilibrium. Vertigo was produced by the sudden

aso-dilatation following the spasm in the syndrome f Lermoyez, but that which accompanied ischæmia f the labyrinth disappeared on sympathectomy, ie consequence of which was a vaso-dilatation of ie labyrinth. Deafness seemed to accompany chæmia of the anterior labyrinth by vaso-constriction. 'he angiospasmodic syndrome of the labyrinth ncluded tinnitus, deafness, vestibular hyperexcitaility, and sympathetic hypertony. The causes of ago-sympathetic troubles were very diverse, and ight be mechanical, endocranial, toxic, or plainly sychic. He attached great importance to the action n the regulating apparatus of the endocrine glands, specially the hormone of the suprarenal gland.

The paper was fully discussed.

Dr. SALISBURY SHARPE contributed a paper ntitled

The Influenza Ear.

The burden of the paper consisted of a plea for arly myringotomy for bulging due to influenza, nstead of waiting for the swelling to burst in the rdinary course, with resultant dissemination of he toxic material, and possible secondary infection. Hæmorrhagic myringitis he considered to be pathognomonic of influenza as the causal agent.

Mr. G. J. JENKINS said that influenza was nswerable for some of the mildest as well as for some f the most disastrous affections of the ear.

Mr. RITCHIE ROGDER agreed as to the great ariability of otitic symptoms met with in influenza pidemics.

Mr. HERBERT TILLEY drew attention to the mportance of using an exhaust speculum after incising he membrane, so as to reduce the possibility of eaving pus in the drum.

The remainder of the morning was occupied with he discussion of clinical cases.

On Friday members of the Sections dined together.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a meeting of this Society held at Leeds on April 27th, Mr. H. LEITH MURRAY (Liverpool), the President, took the chair, and a paper on the

Value of Drainage in Wertheim's Hysterectomy

was read by Prof. FLETCHER SHAW (Manchester). Until recently, he said, his mortality from this operation had been 20 per cent., and even a mortality of 12 per cent. which Victor Bonney had had in his second series placed a dreadful responsibility on the surgeon, especially as so many of the patients who did recover had a very painful and prolonged convalescence. He had tried every suggestion for combating shock, sepsis, and urinary sepsis without much improvement until he found that Prof. Paul Werner in Wertheim's old clinic in Vienna still drained the pelvis by a small wick of gauze running down into the vagina. In the early days this had been the universal practice, but Prof. Shaw had ceased to do it after the first few years because several patients developed ureteral fistulæ, owing probably to the fact that a much larger quantity of gauze was left in the pelvis than was left by Prof. Werner. Since his visit to Vienna he had had the opportunity of doing this operation upon nine patients, all of whom had recovered. A small series like this did not allow of dogmatism, but what struck him much more than the want of fatalities was the straightforward, easy convalescence of most of the patients; though the series was small, he felt he should bring his experience before the other members of the Society, as he felt he had gained more improvement from this small step than any other which had been suggested.

Prof. CARLTON OLDFIELD (Leeds) said that 20 years ago he had employed the gauze pelvic drain. He had, however, discontinued its use, and his results were better than formerly.

Prof. MILES PHILLIPS (Sheffield) did not use the gauze drain. He considered that the most important factor in success following the operation was absolute hæmostasis.

Mr. J. W. BURNS (Liverpool) described a case of

Imperforate Anus.

The patient was aged 31 years and had had three normal labours. She complained of "the womb coming down, and much discomfort on walking." On inspecting the vulva and perineum it was seen that except that there was a small area of pigmentation the anus was absent. The vulva including the fourchette appeared normal. About one inch inside the vagina on the posterior wall a transverse slit with crenated edges was seen which opened directly into the rectum. Above this slit there was a well-marked septum which separated the vagina from the rectum. On bimanual examination the uterus was felt to be slightly enlarged, retroverted and freely mobile. Tubes and ovaries were normal. The coccyx was missing and the sacrum seemed to be deficient. The tissue between the vaginal orifice and the pigmented area referred to above felt very thin. On straining the uterus and bladder came right outside the vulva. In spite of this condition the patient definitely stated that except on one occasion, when she was in the maternity hospital and had been given aperients, she had never experienced any discomfort arising from loss of control over the bowels.

The case presented a distinct problem as to the best line of treatment to adopt so as to cure the procidentia and, if possible, provide a degree of sphincteric control over the rectum. Anterior colporrhaphy was carried out and the bladder pushed up. The cervix was amputated by removing a large cone of tissue and the raw area thus made covered in by vaginal flaps. Next the lower two inches of the rectum were dissected free and a new anus provided in the middle of the pigmentation on the skin. The free end of the bowel was drawn backwards through this anus and united to the skin margins by interrupted catgut sutures. The perineum was then constituted by bringing the lateral tissues together in the midline as is done in the ordinary perineorrhaphy. At the end of three weeks, when the vaginal wounds had healed, the abdomen was opened, the uterus ventrofixed, and both tubes cut across, ligatured and arranged so that the cut ends of each tube were separated by the corresponding round ligament.

The patient, said Mr. Burns, made a very good recovery from both operations and left the hospital in excellent condition. She had very good control over the bowel and could retain a simple enema. It was somewhat difficult to understand how this control over the bowel had come about. The tissues with which the new perineum was constituted could not have contained much active muscle tissue, and he presumed that the original sphincter ani must have been either absent altogether or else atrophied out of existence. The pulling backwards of the bowel might have kinked it so much that abdominal pressure was required to overcome the obstruction and so a certain amount of control was acquired indirectly.

Mr. ALFRED GOUGH (Leeds) described a

Case of Placenta Accreta.

He was asked to see the patient, a primipara aged 26, on account of delay in the second stage of labour. The child was easily delivered with forceps. It was then noticed that there was absolutely no loss of blood, and only after three hours appeared a slightly blood-stained discharge. There was no descent of the umbilical cord. After-pains occurred, but the uterus did not contract as usual into a hard round ball. Pituitrin and ergotin were given, and attempts were repeatedly made to express the placenta, but without success.

It happened that he had recently heard of two disasters following the removal of very adherent placentas—one patient dying immediately from shock and hæmorrhage, the other a few days later of septicæmia—so he decided to leave the placenta in the uterus and to await events. The cord hanging from the vulva was kept dusted with boric powder. He remained within call for 12 hours.

Next day there was no change. The temperature was normal. Crédé's method was again tried without success. On the third day the temperature was 100° F. but the patient's condition was otherwise satisfactory. Attempts to express the placenta again failed. On the fourth day the temperature had risen to 102·8°, and there was general malaise. The lochia were of average amount and not offensive. It was then decided to empty the uterus. Under ether anæsthesia, the placenta was found to be adherent in one or two places and it was readily removed. The uterine

cavity was washed out with copious irrigations of a 1 in 300 solution of lysol. The temperature rose to 103·5°, but next day had fallen to normal and the patient made a good recovery. Soon afterwards, however, signs of pulmonary tuberculosis appeared and she spent some months in a sanatorium.

It might be questioned, said Mr. Gough, whether this was really a case of placenta accreta. It was clearly a morbidly adherent placenta, but perhaps not one of the most adherent. Generally, the diagnosis of placenta accreta had been made after an unsuccessful attempt at its manual removal.

What was the proper course when the placenta could not be delivered in the usual way? Most English text-books said that it must be removed manually after a certain time—one or two hours. Any important post-partum hæmorrhage was, of course, an indication for the immediate emptying of the uterus. In this case, with no loss of blood for three hours and then only a minimal loss, the safer course was the one adopted. The forcible scraping away of the placenta in fragments entailed a grave risk of perforation of the uterus, shock, and hæmorrhage, and the later development of septic complications. A risk of leaving the placenta was, he supposed, that separation might take place and post-partum hæmorrhage occur when no help was at hand; but it seemed unlikely that a closely adherent placenta would suddenly become detached. This fear might have some weight in dealing with a patient in a remote country district, but in an institution it might be entirely disregarded. Then there was the risk of sepsis being favoured by the retention; it had occurred in this case, but was evidently of the sapræmic type.

Mr. J. E. STACEY(Sheffield) described a specimen of bilateral tarry ovarian cysts; the PRESIDENT and Mr. A. A. GEMMELL (Liverpool) reported a case of uterine sarcoma which ruptured and caused acute symptoms in the abdomen; and Mr. W. GOUGH (Leeds) read notes on parovarian and ovarian cysts removed during pregnancy.

EDINBURGH OBSTETRICAL SOCIETY.

AT a meeeting of this Society held on May 9th, Dr. HAIG FERGUSON, the President, took the chair, and a paper on

Maternal Mortality from Puerperal Sepsis

was read by Dr. JAMES YOUNG. He said that the total mortality in these islands was about 4000 yearly; between 1911 and 1926 inclusive there had been 66,421 deaths in England and Wales. The most important single cause was sepsis. For 1926 the total maternal mortality-rate in England and Wales was 5·14, and the sepsis rate 1·60, per 1000 live births. The causes of puerperal sepsis might be clinically considered as: (1) *Contagion*—namely, contact infection with a virulent microbe introduced from without, in which the phenomena were similar to those present in other infective diseases, for example, tetanus, erysipelas. (2) *Trauma*. Here the wound was the primary factor and overshadowed in importance the source and nature of the microbes, which belonged to the widespread micro-organisms capable of causing wound infection. (3) *Auto-infection*. Here the microbes were present in the genital canal before labour or they reached it from some distant source, for example, bowel, teeth, or tonsils. The essential distinction between these three clinical types was not undermined by the fact that in some cases two of the factors might be operating together.

Auto-infection, said Dr. Young, had sometimes been advanced as an explanation of the persisting high death-rate from sepsis in modern times, despite the application of the aseptic principle. That it probably played a minor rôle was, however, suggested by an analysis of the records of large maternity practices. In the Edinburgh Maternity Hospital about a century ago and in other large hospitals—e.g., Dublin—puerperal fever was negligible cause of death when contagion was obviously in abeyance; then years might pass without a death from sepsis. There was similar evidence in extensive modern practices. Thus in the extern practice of the Edinburgh Maternity Hospital there had been 500 successive, spontaneous, normal deliveries with 2 deaths from sepsis; there had been 888 cases in the extern practice of the Birmingham General Hospital with no deaths; whilst there had been 47,593 deliveries in the unselected practice of the East End Maternity Hospital in London with 5 deaths from sepsis, or 1 in about 9500. During 1927, in the practice of the Queen Victoria's Jubilee Institute midwives, there had been 53,502 deliveries with 6 deaths in normal spontaneous births, or about 1 in 8900. On including in this record all the deaths which could directly or indirectly be attributed to sepsis, the maximal figure, including normal and abnormal cases, was seen to be less than 0·5 per 1000. The conclusion was that the very small septic death-rate in these large bodies of women, who could not be regarded as selected from this standpoint, was an argument against self-infection, operating alone, being a appreciable component of the death-rate in the rest of the community. Dr. Young discussed the result of recent bacteriological research, which he said supported this view. The records of the old hospital showed that contagion was the dominating cause of the deaths from sepsis. Instrumentation was the rare—the forceps rate in the Edinburgh Maternity Hospital a century ago was 1 in 472 cases (Simpson)—and trauma was negligible as a cause of sepsis. In the Queen Victoria's Jubilee Institute midwives' practice could be taken as typical of midwives' practice nowadays, contagion (as judged from the incidence of normal cases dying from sepsis) was a negligible cause of death in over 50 per cent. of the midwifery of England and Wales which was in the hands of midwives. He quoted these figures merely because they were the only large records available and not because they necessarily demonstrated any superiority, qua simple contagion, of the midwives over the doctors' practice. He did not think there was any evidence that this was so. Contact infection of the normal by the abnormal and infected case was a risk in modern maternity hospitals, and it was difficult to exclude completely. In Dr. Young's opinion, trauma due to instrumentation was probably the main cause of the present septic death-rate. On analysing the factors at the back of the great increased instrumentation of modern times, he concluded that it was unwarrantable to consider that this was entirely or even largely attributable to malpractice. That with satisfactory antenatal care and an efficient maternity service, the maternal mortality could at once be lowered was, however, supported by the record of the East End Maternity Hospital, London, where during four years in 900 cases the total maternal mortality had been reduced to 0·67 per 1000. Here the instrumental rate was between 2 and 3 per cent.

Dr. Young's conclusions were as follows:—

(1) Autogenous infection is a minor primary cause of fatal puerperal sepsis.

(2) Contagion is probably of comparatively secondary importance. The well-established risks of contact infection in hospitals call for care in the extension of the hospital system of maternity service.

(3) There is evidence that trauma is the most important cause of the death-rate from sepsis. This is not entirely a problem involving the medical attendant; it has implications of a wider nature.

(4) The immediate need is an improved machinery for maternity practice based on a midwife-doctor combination. From the standpoint of immediate policy the importance of this overshadows all other considerations—e.g., "research"—and there is reason for the hope that by this means also a lessening of the death-rate is possible.

(5) Improved education of the public, midwife, and medical student and the assistance of the central and local authorities are all necessary for the creation and working of a satisfactory machine.

Discussion.

Dr. WILLIAM FORDYCE said that the question of segregation of confinement cases in hospitals was important, and he wondered if it was really a good thing for normal cases to be confined in hospitals where there was only a limited amount of space. He thought that forceps delivery in selected cases prevented the trauma that might otherwise be caused by long-delayed labour. He regarded the statistics of puerperal sepsis of 100 years ago as not very reliable.

Prof. JAMES HENDRY quoted three cases of pyrexia of extraneous origin—i.e., from an infective rhinitis, a commencing whitlow, and a septic wound on the skin of the patient's husband—to show the importance which contagion might have. He advocated separate accommodation in maternity hospitals for cases sent in after interference outside.

Dr. DOUGLAS MILLER quoted from statistics of the Royal Maternity Hospital, showing that the incidence of pyrexia in cases delivered instrumentally was much larger than in those whose delivery had been spontaneous. He had found a marked variation in the bactericidal power of the blood in pregnant women, which might explain the variation in individual susceptibility to infection.

Dr. J. M. BOWIE thought the whole machinery of maternity service in this country needed overhauling. This reorganisation might be done in two ways: (1) by the present system of trained midwives working alone in normal cases and assisted by doctors in difficult cases; or (2) a new race of specialists might arise which would devote itself exclusively to midwifery.

Dr. KEPPIE PATERSON attributed great value to prolonged antiseptic douching after delivery even in normal cases, but believed it to be of greater value after manipulative interference.

The PRESIDENT thought that hæmolytic streptococci might be rendered temporarily inert by normal vaginal secretion, but under certain circumstances they might regain their hæmolytic action. He also urged the segregation of complicated cases, but for this a large hospital was required. Trauma was not due only to instrumental interference, as normal labours were often associated with very severe trauma.

Dr. C. W. SOMERVILLE described three confinements complicated respectively by measles, encephalitis lethargica, and diabetes.

Dr. CHARTERIS GRAHAM described ten cases of Cæsarean section performed by himself.

Reviews and Notices of Books.

GYNÆCOLOGY.

By HOWARD A. KELLY, A.B., M.D., L.L.D., and Collaborators. London and New York: D. Appleton and Company. 1928. Pp. 1043. £2 10*s*.

MOST British gynæcologists probably cherish the hope of one day visiting the clinics of the United States and Canada, but for those who find the ideal difficult or impossible to realise we can conceive no better substitute than a careful study of this volume by Howard Kelly and 22 collaborators, each specially expert in the subject with which he deals. This is not a text-book in the ordinary sense of the word; the author would probably say that it is not meant to be. The junior student will not usually find here sufficient pathology to enable him to understand the clinical features of gynæcological diseases; the book is essentially one for the more advanced man who has already acquired a good acquaintance with gynæcological pathology. Out of 49 chapters 18 are from the pen of Kelly himself, and these are amongst the most valuable, recording, as they do, the results of a lifetime of unique experience in gynæcological work. A number of contributions deal with special symptoms in gynæcology and with borderline conditions. For example, there is a good chapter on backache by Robert W. Johnson, one on pneumoperitoneal pontgenography by Rueben Peterson, and a most useful one on psychiatry and mental hygiene by Esther Loring Richards. Ureteral stricture as a possible cause of almost every symptom met with in gynæcological practice is fully discussed by Guy L. Hunner; this condition, it appears, is found in about 12 per cent. of autopsies. Amongst the symptoms it may induce are backache, pelvic pain, pain in the hips and down the thighs, bladder irritability, urinary incontinence, headaches, ovarian neuralgia, dysmenorrhœa, dyspareunia, and menorrhagia; the occurrence of the last symptom is explained by damage to renal function and consequent uræmia. After this terrifying list it is good to learn that stricture can easily be dealt with by ureteral dilatation.

In their attitude to "endometritis" American gynæcologists seem to be even more advanced than ourselves, for as a pathological entity it has almost completely disappeared. Gonorrhœa is described as the typical infection of the female genitalia, but the gonococcus, though it gains entrance to the tubes through the uterine cavity, rarely leaves any significant changes there; even in bilateral pyosalpinx and cervicitis the corpus uteri usually remains normal. The explanation "probably lies in the periodic regeneration of the endometrium." A gonorrhœal endometritis, however, may occur with a lowered resistance as after injudicious instrumentation, a miscarriage, intra-uterine polyps, or an overwhelming infection of the tubes or ovaries. The mucous membrane as well as the musculature of the uterus may be infected from abscesses burrowing into the uterine wall; though the writer (Lawrence R. Wharton) does not say so, we presume that in these cases the mucosal infection never becomes chronic. Few readers in this country will be inclined to disapprove of this iconoclastic attitude towards endometritis as a pathological conception; inflammation of the endometrium was always difficult to demonstrate, and certainly neither teacher, student, nor pathologist will regret the disappearance of the most confusing chapter in gynæcology. Apparently "senile endometritis" has also been discarded; yet in the endometrium after the menopause there is no periodic regeneration. Nor is there any reference to the condition recognised in this country as chronic metritis or subinvolution, with its associated changes in the elastic tissue. Perhaps this is included under the term "myopathic hæmorrhages," though no explanation is given as to what these hæmorrhages are. A clear account of the distinction between the old and the newer teaching would be appreciated by the student-reader, who may be puzzled by a classification quite unfamiliar to him. The chapter on peri-uterine tubal insufflation by I. C. Rubin is especially good, though it is doubtful whether tubal insufflation will ever be practised in this country, as it is in America, as an office procedure occupying five to ten minutes. Endometriomata (Chap. 39) are dealt with by R. M. Lewis, who gives an excellent account of the work of J. A. Sampson, but the reader may well wonder why the subject is discussed also in Chapter 32 under the title of "adenomyoma." The section on menstruation by Emil Novak is adequate yet succinct; it is disappointing to find no reference to the hygiene of menstruation. Why is Fallopian spelt "fallopian" throughout the book, whilst the capitals are retained in Morgagni, Gärtner, Sims, Emmett, Kelly, and Novak?

This book does credit to the editor and his school, and may be warmly recommended to the advanced student and to those who wish to keep in touch with the trend of American gynæcological opinion.

BACTERIOLOGY.

A Text-book of Bacteriology and its Applications. By CURTIS M. HILLIARD, Professor of Biology and Health, Simmons College. Boston: Ginn and Co. Pp. 329. $2.80.

An Elementary Laboratory Guide in General Bacteriology. By HAROLD J. CONN, Soil Bacteriologist, New York Agricultural Experimental Station. London: Baillière, Tindall and Cox. 1928. Pp. 165. 13*s.* 6*d.*

GRADUALLY it is becoming recognised that bacteriology, while it may yield results of use in medicine, chemistry, industry, agriculture, and other activities, is a separate science, worth cultivating for its own sake. Books purporting to deal mainly with one of its branches should have their scope indicated in their titles, whereas a text-book of bacteriology should survey all its developments impartially. Prof. Hilliard has provided an excellent example of the general text-book. It is concise, nearly always accurate, and covers the whole field, but without dealing exhaustively with any one branch. Perhaps most attention is devoted to the bacteriology of foods such as milk, milk products, canning and other food preservation processes, shell-fish, &c. The bacteriology of water is also discussed in some detail, while there is a short but clear account of soil bacteriology and its economic importance. The more purely medical aspects only occupy four of the 21 chapters, and this account would be of very little use to the medical student. It does serve, however, to provide the general student with a brief outline of the relationships of bacteria to disease. These sections contain a few doubtful or inaccurate statements. For example, it is stated that the chief source of tubercle bacilli in milk is manure flakes and that an infected udder is a rare source of infection; that food poisoning is largely due to bacteria which can live saprophytically (this is only true of botulism); and that diarrhœal diseases in babies are caused by massive numbers of bacteria in milk regardless of their varieties or sources. For the most part, however, the teaching is orthodox and modern. A good many directions for practical work are included, although the book would not serve as a laboratory text-book. The volume can be recommended as a clear, comprehensive, and not too detailed general account of bacteriology.

If text-books on general bacteriology are rare laboratory manuals suitable for the student of all branches are still rarer. In many ways Mr. Conn's book is a model of its kind. It deals only with the elements of practical bacteriology, but it deals with them in a highly competent manner. The student, no matter whether of medical, agricultural, or commercial bacteriology, who has worked through the brief course outlined in its pages should by so doing have become possessed of a very sound knowledge of the ground work and should be able to select his further activities with discretion.

NOTABLE BRITISH TRIALS.

Trial of S. H. Dougal. Edited by F. TENNYSON JESSE. London and Edinburgh: William Hodge and Co. 1928. Pp. 236. 10*s.* 6*d.*

MANY of the "Notable British Trials" have turned mainly upon medical evidence. The Moat Farm murder was not one of them. Dougal, found guilty of that crime in 1903, had served in the ranks of the Royal Engineers for over 21 years and earned a "very good" discharge. While stationed in Canada he lost two wives in quick succession; both died after sudden illness and in great pain, and it is difficult, in view of his subsequent history, to resist the suspicion of poisoning. If the accusation were true, it is odd that he finally resorted to the bullet to dispose of Camille Holland, the little elderly lady whom he had persuaded to come and live with him at the Moat Farm, near Clavering, in Essex. Before this happened he had married a third wife in Dublin, not to mention other less regular unions. He had also been convicted, after leaving the army, of an ingenious cheque forgery which cost him a year's hard labour and the loss of his pension. Coming out of prison penniless, he somehow made the acquaintance of Miss Holland, a woman of strong religious feelings, good up-bringing and education, and possessing a fortune of £7000. Three weeks after they had established themselves with her money at the Moat Farm she disappeared. Four years later her body was found, with a bullet in the skull, in a ditch which Dougal had been filling in at the time. Meanwhile, Dougal, though he had explained her disappearance by saying that he had seen her off to London by train, had written to her bank, in her name, from the Moat Farm address, had drawn all her money on forged cheques, and had sold all her investments. He sent for his wife to join him, at first passing her off as his daughter. She presently ran away with a farm labourer, but Dougal was never at a loss in finding feminine companionship. Divorce proceedings in 1902 brought publicity, and early in 1903 the police became busy. Dougal was arrested on a charge of forgery and, after weeks of weary digging in the moat, Camille Holland's body was found. Mr. A. J. Pepper, the surgeon called by the Crown, gave evidence that the wound could not have been self-inflicted. Though the case was clear, the judge's summing-up seems brief in these days when judges must remember the Court of Criminal Appeal. Dougal's counsel dared not put him in the witness-box and, oddly enough, the judge, the late Mr. Justice R. S. Wright, did not comment on the fact. Miss Tennyson Jesse, who has skilfully edited the account of the trial, brings out the fact that Dougal was certified insane after the forgery conviction in 1896, and served the whole of his sentence in Cane Hill Lunatic Asylum. Insanity, however, was of course no part of the defence at the trial.

JOURNALS.

MEDICAL JOURNAL AND RECORD.—The issue of this newspaper for April 18th contains an instalment of an interesting symposium on neuro-psychiatry from a group of well-known American physicians. We may note in particular a genetic study of mongolism by Dr. Ira S. Wile and S. Z. Orgel, in which the conflicting views of various authorities are set out, but only to find that the theories studied were inadequate to explain the phenomena. Another article in the same issue is a sketch of the Royal Society of Medicine, giving a short account of its origin as the Medical and Chirurgical Society and its development into an Academy of Medicine in all but name. The article is well illustrated, but contains certain obvious misprints, inasmuch as the roll of the Society is said to show 371 honorary Fellows, 24 Associates, 426 corresponding members, and 480 members. The correct figures should be according to the latest roll of the Society 38 honorary Fellows, 3749 Fellows, 40 Associates, 157 corresponding members, and 450 members. Also the incorporation of the ophthalmological library with the main library has escaped the attention of the writer, who, however, does justice to the library as the most comprehensive medical library in the Empire, and also as an admirable resort for medical authors who require facilities for intensive study, for bibliographic details and dates, and for references in general. In fact the writer puts up a strong plea in support of his frank suggestion that a transatlantic millionaire should, with a stroke of his pen, remove certain liabilities. We know that the Society has grave financial commitments, but the business-like way in which its affairs are now managed has proved that complete stability is on the way. None the less the cause of medicine, not only in this country but in the world, would be benefited if the pecuniary stress of the Society were relieved.

THE LANCET.

LONDON: SATURDAY, JUNE 9, 1928.

CLINICAL APPLICATIONS OF OVARIAN EXTRACT.

SINCE the dictum of HELMONT, "Propter solum rum mulier est quod est," our knowledge of arian function has progressed very far. It had long en known that castration in women is followed by ressive changes in the genital organs with atrophy the uterus, but the experiments of E. KNAUER owed that if the ovaries are removed from their ce and implanted elsewhere in the body atrophy the uterus does not occur. From this it was a ural step to make use of a subcutaneous injection ovarian extract. At first these attempts met with le success. Thus BUCURA in 1907 found that ections of "ovarin" into castrated animals was l followed by atrophy of the uterus, and he con-ded that its exhibition merely reduced to a certain ent the obesity which follows castration. The t important positive result was obtained by ADLER, who in 1912 showed that it was possible using crude watery extract of whole ovary to duce the typical signs of œstrus in animals. In E LANCET last week Prof. E. C. DODDS reviewed ne of the experimental findings; he traced the ious steps from KNAUER'S observations in 1900 il the preparation by E. HERRMANN and L. AENKEL of active oily extracts capable of producing trus in spayed rats. The story of this work and the standardisation by biological methods of the ive extract is familiar to our readers. Prof. DODDS nts out that oily extracts have certain disadvan-es for clinical purposes, and that many workers ve tried to obtain an active extract in watery ution. Recently he and his colleagues succeeded preparing, by an elaborate chemical process of ich he gives the outline, a clear watery solution of ubstance (or substances) possessing the property producing œstrus in rats in very high dilution. e preparation is without action on the blood ssure, it gives rise to no local reactions, and even given in large doses it seems to be non-poisonous he ordinary sense of the term. The œstrus-producing rmone is present in the liquor folliculi as well as in ier parts of the ovary, and also in the placenta. man placenta, being easily obtainable, has been d as the source of the extract. One kilogramme of sh placenta gives about 150 to 200 units, the unit ng the smallest dose required to produce œstrus 10 out of a series of 20 rats. It is hoped that this ter-soluble extract will shortly be available in antities suitable for clinical use.

Prof. DODDS approaches with considerable diffidence e question of the clinical applications of ovarian ract which produces œstrus in animals, this ques-n being bound up with the still uncertain relation menstruation to œstrus. A large amount of literature results of clinical trial is available, but most of deals with extracts that have not been standardised biological tests, and is therefore of little scientific lue. There are many directions in which clinical ults might be expected to follow administration of arian extract in suitable doses. It is possible that ections may be of value in hastening the onset of menstruation in cases of delayed puberty. HERRMANN and FRAENKEL stated in 1918 that if their oily preparation were administered subcutaneously to prepuberal rabbits the onset of premature puberty was noted. If the onset of puberty was marked not only by the appearance of œstrus but also by ovulation, and therefore by full development of the genital organs (which can be shown externally in rats by canalisation of the solid vagina), a similar effect might reasonably be expected in the human female. Before the extract could assume clinical importance in this connexion the production of ovulation would be necessary, since it is difficult to see what advantage, unless it be a psychical one, could be derived from the mere establishment of an artificially induced menstruation without preceding or accompanying ovulation. That ovulation is not an essential antecedent to the production of œstrus is shown by the fact that œstrus is produced in spayed rats by mere injection of the hormone. Ovarian extract might, however, be of use in mitigating the discomforts of an artificial menopause after removal of both ovaries by operation, even though the uterus had been removed at the same time, and the resumption of menstruation could not be looked for; or again it might serve to lessen some of the unpleasant phenomena of the natural menopause or even to delay the onset of the climacteric in women who desired for any reason such an interference with the course of nature. There are certain cases of sterility which may be due to ovarian hypofunction resulting in the production of immature ova incapable of fertilisation. Some years ago A. ROBINSON[1] showed that in ferrets a large amount of sterility and even intra-uterine death might be due to the production of ova incapable of development. The injection of active ovarian extract might therefore be of value in certain selected cases of sterility by bringing about a fuller development of hypoplastic ovaries.

Experimental evidence on pregnant animals indicates that the hormone may have an important action in terminating pregnancy. If this is borne out by clinical trial, a certain and harmless means of inducing labour either at term or prematurely would be at our disposal, in place of the troublesome and sometimes dangerous methods at present in use. It has been found that the hormone will cause abortion if given in large doses to laboratory animals. Its mode of action is doubtful. It is probably correct to say that pro-œstrus, which is believed to correspond (at least in its earlier stages) to the premenstrual phase in women, is the result of a hormone (or hormones) derived from the developing Graafian follicle, and from the developing corpus luteum. If conception occurs and the fertilised ovum is implanted, the premenstrual decidua continues to change into the decidua of pregnancy. This further development may now be aided by additional hormone derived from the placenta and possibly from the fœtus (STARLING and LANE-CLAYPON). It may be that there is a nice regulation of this hormone so that hyperæmia of the developing decidua is never excessive, and is so adjusted that it causes the maximum decidual reaction without being sufficiently intense to lead to transudation of blood into the stroma, from rupture of vessels or otherwise, which might give rise to detachment of the ovum. If extra hormone is supplied by subcutaneous injection, it might well be excessive and lead in animals to abortion or premature labour. A difficulty arises, however, when we attempt to use this theory to explain

[1] THE LANCET, 1921, i., 1030.

abortion or premature labour in women. Menstruation in women may be looked on as a "menstrual abortion," and as analogous to abortion of a fertilised ovum or premature labour in that the entire decidua is cast off. But the modern view of the cause of menstruation is that it is mainly due to *degeneration* of the corpus luteum, and therefore to loss of the hormone derived from it and from the liquor folliculi, and that only a very small part of the hæmorrhage is derived from over-distended capillaries at the climax of the premenstrual phase. The cause of abortion or premature labour should, by analogy, be somewhat similar. Now, at least in the early stages of pregnancy, the corpus luteum is *not* degenerate, and the placenta is developing; from these two sources presumably the supply of hormone that leads to the production of the premenstrual and pregnancy decidua is constantly being maintained. On this showing, injection of the œstrus-producing hormone could do nothing more than accentuate the effects of the latter; there would be no reason why it should lead to abortion or premature labour.

It seems therefore doubtful whether the ovarian extract is capable of producing menstruation unless it does so by first causing ovulation; for example, menstruation might not result from its injection if the ovaries had been completely removed. On the other hand, it might, if given in sufficiently large doses, be capable of producing abortion and premature labour by causing uterine hyperæmia and consequent rupture of decidual vessels. The abortion so caused would not be comparable to a "menstrual abortion," as it would not have been produced by any degenerative process in the corpus luteum. It is conceivable that ovarian extract might assume not only therapeutic but also medico-legal importance, if in unscrupulous hands it could be used for the production of abortion. Regarding this possibility it is useless to speculate at the present stage. Prof. DODDS states that a watery extract will shortly be available in quantities for clinical trial, and the medical profession will watch with interest the results obtained from its use. Meanwhile it should be noted that abortion is usually easy to procure in laboratory animals, and notoriously difficult in the human female.

THE INHERITANCE OF BLOOD GROUPS.

SINCE the pioneer work of E. VON DUNGERN and L. HIRSCHFELD was published in 1910 the inheritance of the blood groups has been assumed to depend upon the existence of two dominants and two recessives. The dominants, usually described as A and B, correspond to the agglutinable factors or agglutinogens of the red cells, whilst the recessives, which are allelomorphic to the dominants, correspond to the agglutinins of the serum, and are known as *a* and *b*. In 1925 BERNSTEIN [1] on mathematical grounds, came to the conclusion that distribution of the groups in the general population could not be explained upon DUNGERN and HIRSCHFELD'S theory, but required the postulation of three multiple allelomorphs, two dominant and one recessive. Accepting the existence of the original dominants A and B, he replaced the two allelomorphs, *a* and *b*, by a single recessive which he called R, but which has since become known as O, because it merely signifies the absence of both A and B. According to BERNSTEIN'S hypothesis the agglutinins do not come under hereditary control at all, and the genetic formula of the four groups is as follows: Group 1 (Moss), AB; Group 2, AA or AO; Group 3, BB or BO; Group 4 (Moss), O. Should this prove correct it must considerably modify our views upon inheritance of the groups. From the theory of DUNGERN and HIRSCHFELD it followed that in any mating involving the presence of both the A and B factors in one or both parents, the children might be of any group. But BERNSTEIN, whilst agreeing that in all matings not involving a parent of Group 1 (AB) the groups of the offspring will occur according to the older hypothesis, believes that those involving a parent of the genetic constitution AB cannot produce offspring having the recessive O. In other words, a parent of Group 1 (Moss) cannot have a child of Group 4 (Moss). It further follows that matings between parents of the genetic formulæ O and AB can never result in offspring of the formula O or AB.

Individuals of the genetic constitution AB—i.e., of Group 1—are rare in the Western world, and it has been difficult to collect enough matings involving parents of this group to test the truth of BERNSTEIN'S views. Up to 1925 84 examples of such matings, resulting in 239 offspring, had been recorded, and the results were tabulated by SNYDER,[2] who found that in 34 out of the 239 cases the groups of the offspring did not fit in with the new theory. At first sight it might seem that so large a proportion (13 per cent.) of exceptions to the rule must prove fatal to BERNSTEIN'S hypothesis. SNYDER, however, himself examined nine matings involving parents of Group 1 and found no exceptions, and examination of the protocols in a certain number of the instances in which Group 4 children were said to issue from matings involving Group 1 parents discloses the fact that the child's group was reported within the first few months of life solely on the evidence of the agglutination of the red cells by known sera of Groups 2 and 3, and without taking into consideration the agglutinins of the serum. HAPP [3] has shown that the agglutinable factors of the red cells may not appear until the second year of life, and DYKE has recently demonstrated in our own columns [4] that a possibility of error is inherent in the use of grouping sera of insufficiently high titre; so it is more than probable that a great many of the offspring reported as belonging to Group 4 (Moss) actually belonged to some other group, and therefore constituted no exceptions to the rule. At any rate it is obvious that in so far as it bears upon this question, almost all the work performed upon the blood of newly born children must be left out of account.

Very strong support for the Bernstein hypothesis has lately been offered by Prof. OLUF THOMSEN [5] in a report to the Société de Biologie of Paris. Prof. THOMSEN has collected data concerning the groups of the offspring in 165 marriages involving members of Group 1, and with one exception—in which there were excellent grounds for disputing paternity—his results conform completely with those which BERNSTEIN would have expected. There is very strong reason to believe that his hypothesis is correct, and if it proves to be so, it will serve as a monument to the value of the deductive method and to the propriety of bringing mathematics to bear on biological problems. Prof. THOMSEN'S laborious investigation, the most important contribution so far on the inductive side, will go a long way towards

stablishing the theory on a firm basis. The narrowng of the possibilities of paternity in any given ase involving parents of Group 1 would, of course, e of great importance in legal medicine.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

THE Welsh National School of Medicine is confronted with another crisis, one of the most serious n its turbulent history. Hitherto the students f the School of Medicine have received their clinical nstruction at the Cardiff Royal Infirmary, but the oard of management of the infirmary have given otice to the University College of South Wales and Monmouthshire to terminate this arrangement at he end of the month. It is true that the board has xpressed its readiness to enter into another agreeient which would enable the medical school to be arried on, but, it is understood, only under such onditions as would give practically complete control f the clinical school to the honorary staff of the nfirmary, a condition which the University is not ikely to accept. The trouble has been brewing for ome considerable time—indeed, since the very nstitution of a complete medical school—for the introuction of professorial units at the Royal Infirmary vas never welcomed by the honorary medical staff. Exactly a year ago the matter became acute when, vithout warning and at the end of the academic ear, the College authorities were suddenly faced vith the resignation from the office of clinical teacher f three senior surgeons of the infirmary staff. It vas urgently necessary to provide for the instruction f the students already attached to the school, and or those who proposed to join in October; moreover, he resignations would have diminished the beds in he charge of recognised teachers to a number so mall as to be incompatible with the continued ecognition of the clinical school by the University f London and the Conjoint Board. The College herefore agreed to the demands of the infirmary taff and admitted five staff representatives to eats on the faculty of medicine. Even this conession has not had the desired effect, and the position s now so serious that it is difficult to see a solution. t is clear from the reports in the local press that ersonal considerations are an acute element in the ituation. At the meeting of the board of manageient of the infirmary, as reported in the press, tatements were made for which there is little justifiation, and arguments were used which were, from very point of view, regrettable. But this kind of hing has happened before in the attempt to graft new organisation into an existing institution. With goodwill most difficulties can be smoothed away, nd it is to be hoped that Cardiff may yet prove self a worthy host of a complete national school of iedicine.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.—The fifth annual congress of this Association was held in London last week, under the chairmanship of the President, Sir Arthur Stanley. Mr. J. C. Stobart, the Director of Education to the British Broadcasting Corporation, discussing the use of wireless for hospital appeals, said that one of the London hospitals could in future expect an appeal every year as in the past. He thought that the preferable course would be that they should agree among themselves as to the priority of their claims in a given year. At the dinner which followed the congress Sir Arthur Stanley expressed his belief that the suggested compulsory insurance of motorists in the interests of the hospitals was quite impossible on the ground that if the motor insurance companies were compelled to take any and every risk, premiums would be greatly increased.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

THE list of honours issued on the occasion of the King's birthday contains the name of Prof. J. S. Haldane, who has been created rightly a Companion of Honour. The members of the medical profession marked out for distinction are as follows: Lieut.-Colonel Sir William Thomas Prout, Senior Medical Advisor to the Colonial Office, is promoted to K.C.M.G., while knighthoods are conferred upon Dr. James A. Hosker and Dr. Thomas Watts, M.P., for political and public service. In the Order of the Bath, Colonel Harold Bolton, I.M.S., V.H.S., Assistant Director of Medical Services in the Deccan District, and Major-General Harold B. Fawcus, K.H.P., Deputy-Director-General, A.M.S., receive the C.B.; and in the Order of St. Michael and St. George, Dr. J. Hope Reford, lately Director of Medical and Sanitary Services in the Uganda Protectorate, becomes a Companion. Dr. Alfred Bakewell Howitt receives a C.V.O., and Khan Bahadur Ahmed Bakhsh, Assistant Residency Surgeon and Personal Assistant to the Administrative Medical Officer in Central India, a Companionship of the Imperial Service Order. In the Order of the British Empire, Colonel Howard Ensor, C.M.G., D.S.O., R.A.M.C., Deputy Director of Medical Services in the North China Command, Surgeon-Captain James H. Fergusson, R.N., Major John H. Hebb, R.A.M.C. (Retd.), Director of Medical Services Ministry of Pensions, and Dr. John E. Strathearn, Warden of the Hospital of the Order of St. John of Jerusalem in Palestine, receive the C.B.E.; Prof. Albert V. Bernard, M.O.H., Malta, Dr. J. G. Lyon Brown (for services in connexion with the emergency Volunteer Corps at Hankow), Dr. George R. Footner, Director of the Omdurman Civil Hospital, Major James H. Martin Frobisher, R.A.M.C., Surgeon-Commander Walter K. Hopkins, R.N. (Retd.), Medical Officer to the Board of Customs and Excise, Lieut.-Colonel Humphrey F. Humphreys, R.A.M.C.(T.A.), Surgeon-Commander Bryan Pickering Pick, R.N., and Major Gordon Wilson, R.A.M.C., become Officers of the Order. Dr. James F. Corson, Assistant Bacteriologist of the Medical and Sanitary Department, Tanganyika Territory, Dr. George Maclean, Sleeping Sickness Officer Tanganyika Territory, Dr. Yeshua Shami, M.O., Department of Health, Palestine, and Dr. E. H. Gillson, I.M.S., become Members of the Order. In the Order of the Indian Empire, Lieut.-Colonel Ernest W. C. Bradfield, I.M.S., Professor of Surgery at the Medical College and Superintendent of the General Hospital, Madras, Lieut.-Colonel Lewis Cook, I.M.S., Civil Surgeon Bhagalpur, Bihar and Orissa, Lieut.-Colonel John Cunningham, I.M.S., Director of the Pasteur Institute at Kasauli, Lieut.-Colonel George D. Franklin, I.M.S., late Chief M.O., Delhi, and Dr. Hugh G. Roberts, Welsh Mission at Shillong, Assam, receive Companionships. The following have been awarded the Kaisar-i-Hind Medal of the first class for public service in India—namely, Dr. R. J. Aston, Kachwa, United Provinces, Mr. C. F. Frimodt-Moller, Medical Superintendent of the Union Mission Tuberculosis Sanitorium, Madanapalle, Madras, and to Miss A. C. Smith, in charge of the Zenana Hospital of the Church of Scotland Mission, Guirat. Father Alphonse Fargeton, superintendent of the Rangoon Leper Asylum, has also been similarly honoured. In the name of the medical profession we offer congratulations to all these recipients of well-deserved honours.

THE REVIVAL OF THE VOLUNTARY HOSPITALS.

THE Voluntary Hospitals Commission has marked the conclusion of its labours by the issue of a final report which we summarise on a later page. This report is full of encouragement. Three years ago the accommodation in the voluntary institutions was short by 10,000 beds of what was required to provide a reasonable standard of adequacy, and a grant of public money towards new construction was regarded as the one obvious means of filling this huge gap. The national finances, however, were already heavily overburdened, and the grant was not forthcoming. Hospital administrators, thus put upon their mettle, thereupon determined to do for themselves what could not be done for them. The result of this determination, and of the energy with which it has been pursued, has been an expansion more rapid and more widespread than the Commission had anticipated. During the two years and a half between the middle of 1924 and the end of 1926 the rate of expansion has considerably exceeded the provision required to keep pace with the growth of the population. According to the judgment of a Commission, composed mainly of men of wide experience of hospitals, either as medical men or administrators, the proper ratio of beds to population is 1·6 per 1000, and on this basis it was necessary to provide in the two years and a half 1020 beds to meet the increase of population. The efforts of the 30 months actually provided not very far short of four times that number of beds—3829, or 2809 more than were required to meet the growing demand. The result is even better than the annual average of 1124 beds, the ratio of increase in 1926, the latest period for which figures are available, having been appreciably higher, while there is every reason to hope that the peak has not yet been reached.

As regards the finance of new construction the position is still more hopeful. In London the receipts for building purposes in 1925 and 1926 averaged more than double those of the three years, 1922–24. Figures for the provinces are not available—a circumstance which suggests once more the need for a bureau of hospital information—but the Commissioners have ground not only for believing that the amounts appropriated for building have substantially increased, but for expecting further improvement in the rate of progress. Our columns from week to week bear witness to the extent of current expansion, especially in the provinces. Simultaneously with the influx of money for building, maintenance income is likewise increasing. In 1925, which is now quite a long time ago, statistically speaking, the excess of income over expenditure was nearly three-quarters of a million, or over £100,000 more than in the previous year, notwithstanding that a substantially larger number of beds had to be maintained. Some of the most important hospital centres are, however, as yet unable to meet their expenditure. This is an especially serious state of things as concerns large general teaching hospitals. That they should be able not only to pay their way but to enlarge their opportunities is a matter of vital concern, since, as the report points out, failure to do so must "eventually react to the prejudice of the voluntary system," and, it may be added, to our whole system of medical education.

Finally, the retiring Commission faces the question: Whence are these institutions, not only the great teaching hospitals, but hospitals of all kinds, to obtain the accessions of income necessary to meet rapidly growing needs, to cope with the demands of widely increased circles of patients, and to lessen those long waiting-lists which cause so much dissatisfaction? Legacies are broken reeds; private contributions, generous as they are, are woefully insufficient, and the only hopeful source of future substantially increased income appears to the Commission to be the contributions of the industrial classes. Most of the hospitals which are keeping pace with demands that will never stand still draw revenue from "penny in the pound" or similar schemes. New schemes of the kind are constantly being started, not only in great centres of population such as Birmingham and Liverpool, to name the two most recent instances, but in districts which serve a large scattered population. So far as we are aware there have been no failures, and hitherto the hospitals have, generally speaking, avoided the obvious risk of creating in the minds of contributors expectations which might not always be fulfilled. That hospital finance must in the future be based, to a very large extent, upon mass contributions, is so obvious as to be on the way to becoming a truism. The report naturally has something to say upon the most urgent problem which at present confronts a serious proportion of our hospitals—the demands made upon them by the vast number of traffic casualties, most of which are the result of the madness of speed. The Commission favour "some system" of that compulsory insurance, which Sir Arthur Stanley has just dismissed as impossible, chiefly on the ground of the high premiums which would be required to safeguard insurance companies obliged to accept any and every risk. But the risks under a compulsory system would be exactly the same as at present, with the addition of provision for hospital treatment which would probably involve only a relatively small addition to the premiums. In any case we cannot much longer continue to cure tens of thousands of victims of road accidents at the expense of private benevolence or the pence of the working man.

QUALIFICATION AND AFTER.

AT the summer session of the General Medical Council which closed last week it was as usual the disciplinary measures which largely occupied the Council's time and exclusively the interest of the public; but the report of Committees which we now publish indicates that there are other aspects of the Council's work which deserve attention. We reproduce a chart appended to the report of the Finance Committee showing the number of medical students and practitioners on the British list from 1908 to 1927. This chart was prepared simply to give the Finance Committee some grounds for estimating the receipts from registration fees, which are the principal source of the Council's income. These receipts showed a decrease last year of more than £1400, owing to the diminishing entry to the medical profession; and the report declares that the number of practitioners is likely to decrease further for the next two or three years in consequence of the falling off of students which occurred in 1923 owing to the new regulations. This low-water mark in 1923 was a striking event to which attention was called in our columns at the time,[1] and a graph was drawn dealing with the figures for the preceding quarter of a century and the effect of war conditions upon them. It was then suggested that the diminution might have its root partly in economic conditions—possibly in a belief among parents that the medical profession was likely to be overcrowded and therefore not to present a fair prospect of livelihood. It was, however, evident that the surprisingly low figure of 1923 was in some degree an interregnum, for a certain number of students, who would no doubt under the old regulations have begun the study of chemistry and physics in October, only began their pre-registration work at this time and therefore remained unregistered until the following year. We may now assume that there were further factors at work in causing the diminution of 1923 other than the mere technical postponement of registration owing to the new regulations, for the level of medical student entry from 1924 to 1927 is seen to vary between the limits of 1050 and 1250, whereas in the decade 1900–10 the line remained fairly steady about the 1500 level. The Council's chart brings out another point of great interest, which is

[1] THE LANCET, 1924, i., 579.

the wastage of medical students owing to the fact that a certain proportion who register as students never proceed to their final qualification. This is ingeniously shown in the chart by drawing a curve of registered students who should have completed the six years curriculum, and superposing it on the actual qualification figures. During the years 1918–21 the difference in level between these two curves is very striking, indicating how many students of medicine omitted to complete the curriculum on their return from active service in the war, at any rate in the normal time. In 1923–24, however, the number of practitioner registrations was considerably in excess of those entering six years previously. This may have been due partly to the retarded qualification of men who would have been in the 1918–21 group of registered practitioners had they not been on active service, and partly to the advancement of some of the 1925 group, helped by the concessions and facilities for qualification in less than the regulation period offered to ex-Service students by the examining bodies. In 1925 there was actually a deficit of 1000 on the expected practitioner registration. These wide fluctuations due to post-war circumstances are not likely to be repeated, and the curves show a tendency again to resume their normal courses. In regard to wastage after qualification, the Medical Women's Federation has reacted to a statement, loosely made in some quarters, that 50 per cent. or thereabouts of women who qualify in medicine drop out of practice later owing to marriage, when it is presumed they cease from working at their profession. In order to test the accuracy of this statement the Federation has sent out a questionaire to a 1000 of its members living within the British Isles. Replies received in 95·5 per cent. of inquiries indicate that only 9 per cent. of the total number have dropped out of practice, the figure including a number who only retired after many years of active and successful practice. A further analysis is given in regard to the career of 644 medical women who qualified from metropolitan schools during the years 1923-25. Of these only 63 were known to have retired from practice, 62 of them (less than 10 per cent.) on marriage, whereas 41 others who married are known to be still working at their profession. It would be interesting to compare these figures with the wastage in the medical profession at large, but we do not know of any comparative figures on which conclusions could be based.

COURSES IN TUBERCULOSIS.

As already announced, the Joint Tuberculosis Council is arranging a series of post-graduate courses during the summer months, details of two of which have now been issued. At the Treloar Cripples' Hospital and College, Alton, Hants, the programme will extend from June 25th to 30th, the inaugural class meeting Sir Henry Gauvain, the medical superintendent, at 11 A.M., on Monday, the 25th. The subject-matter of lectures will include the organisation and staffing of a hospital for surgical tuberculosis, the diagnosis and treatment of tuberculous disease of the spine and hip, peritoneum and glands, as well as instruction in the technique of heliotherapy, plaster-making and aspiration of abscesses. Dr. R. G. Bannerman will deal with light treatment from the bacteriological standpoint, Dr. W. S. Duke-Elder with tuberculous disease of the eye, and Dr. J. E. Wood with light treatment in pulmonary and non-pulmonary tuberculosis of adults at King George's Sanatorium, Bramshott. On Saturday a visit will be paid to Sandy Point, Hayling Island, where sea-bathing is used as a therapeutic measure. At Cambridge, by arrangement with Dr. P. C. Varrier-Jones, a programme has been arranged from July 2nd to 7th, to be opened with an inaugural address by Sir Humphrey Rolleston on the Monday afternoon. Lectures during the next three days will include The Mental Factor in Tuberculosis by Dr. J. T. MacCurdy, Demonstration of Parasites by Prof. G. H. F. Nuttall, Chemotherapy and the Tubercle Bacillus by Prof. W. E. Dixon, a demonstration by Prof. J. B. Buxton, and lectures by Dr. W. Paton Philip and Dr. Louis Cobbett. On Friday there will be an all-day visit to the Papworth Village Settlement, and on Saturday morning a demonstration by Prof. H. Roy Dean, on the Anatomical and Microscopical Changes present in Tuberculosis. In the case of both these courses no fee will be charged for the lectures or demonstrations, and the Minister of Health has been asked to allow expenses to rank for grant. Applications should be addressed to the Hon. Sec., Joint Tuberculosis Council Post-Graduate Courses, The Larches, Farnham Royal, Bucks.

LIVER TREATMENT OF PERNICIOUS ANÆMIA.

THE May number of the *American Journal of the Medical Sciences* contains two new papers by Minot, Cohn, Murphy, Stetson, and Lawson on the treatment of pernicious anæmia. Having now had a very large number of patients under observation they are able to trace in greater detail than before the effects of using whole liver or liver extract. They roughly divide the cases into two classes, according to whether the red cell count is below 2½–3 million, or is above that figure. They say that in the latter class little or no reticulocyte response occurs as a result of liver treatment, though the red cell count rapidly rises, and this fits in with the fact that in such cases the marrow picture, as shown by bone punctures, is more or less normal (normoblastic). In the former class, consisting of cases with low red cell counts, typical reticulocyte responses are found; and it is in this group, according to their own findings and those of Castle and Peabody, that typical megaloblastic marrow is seen. This marrow picture is rapidly transformed by the use of liver, and it is thought that the simultaneous transformation of the marrow and the rapid rise and fall of the reticulocytes in the circulating blood are intimately connected, the reticulocyte being the result of a rapid maturation of the megaloblast. The number of reticulocytes per cubic millimetre at their peak is found to be inversely proportional to the red cell count at the beginning of treatment, an observation which can be employed either in estimating the potency of a new extract or in substantiating a doubtful diagnosis. These facts, it is pointed out, all support the view that pernicious anæmia is a result of faulty development of the red cells rather than of undue hæmolysis.

In reference to the amount of liver or extract which should be used, details are given of the response made by patients who were fed on doses too small to produce a maximal effect; from these it is deduced that the actual reticulocyte output per unit weight of liver is, within certain limits, roughly the same in every case, all the material supplied being used by the body. When full doses are given, some patients are able to employ more of the specific substance than others according to the condition of the marrow. This factor is obviously unknown at the beginning of treatment, but the American investigators consider that 300–400 g. of liver per day is enough in most cases, although patients in a critical condition should take 500–600 g., preferably in the form of an extract. A maintenance dose should be found for each patient when the red cell count is normal, since relapse will follow if liver treatment is discontinued. Two cases are mentioned in which thrombosis developed after very large doses had been given. In discussing the use of liver in other forms of anæmia, they say that true secondary anæmia presents quite a different problem; 45 cases treated showed no improvement comparable to what might have been expected in the Addisonian variety. Five cases of doubtful origin did, however, give a typical response. Two of them were anæmias occurring in pregnancy, and the other three suggested primary disease of the blood, but were unlike pernicious anæmia. Mention is made of a good response

being obtained in treating a case of infection with *Dibothriocephalus latus*, which is known to cause an anæmia of the primary type.

In a third paper, by Cohn, Minot, Alles, and Salter appearing in the May number of the *Journal of Biological Chemistry*, an interesting account is given of the methods employed in making liver extracts. Further purification of the extract referred to in the other two communications has been obtained by precipitation with phosphotungstic acid. A fraction of this precipitate is formed of phosphotungstates of a substance which contains about 19 per cent. of nitrogen, and which is probably of the nature of a polypeptide or a nitrogenous base; only 0·6 g. of this is necessary per day to produce a good reticulocyte response in a case of pernicious anæmia. Hitherto it has been necessary to test such extracts by observing their effect on patients, but it is mentioned that F. R. Sabin, of New York, has recently found that abnormally rapid development takes place in the megaloblasts of chick embryo preparations treated with potent liver extract. Also alterations in human reticulocytes in the presence of extract have been observed by Emerson. The advantage of this discovery to those engaged in the study of the specific substance contained in liver will at once be obvious.

EXCESS OF IRRADIATED ERGOSTEROL.

IT has always seemed possible, though not very probable, that injury might be caused by excessive doses of any vitamin. Several workers have attributed certain symptoms to administration of an excess of vitamin A or of vitamin B, but the specificity of the intoxications described has not been definitely established. A. Kreitmair and T. Moll [1] (1928), however, give an account of a hypervitaminosis with vitamin D, which sounds really alarming. Their attention was focused on the subject by an article in which W. Pfannenstiel [2] (1927) described the effect of feeding half-grown rabbits with various doses of a preparation of irradiated ergosterol. Small doses raised the bactericidal power of the blood, but large doses caused severe cachexia and death. This observation agreed with the experience of Kreitmair and Moll, who had noticed that a daily dose of 20 mg. of irradiated ergosterol brought about the death of white mice in about six days. They therefore decided to make a much more thorough examination, using a variety of animals and noting the symptoms carefully. For white mice they found that 1 mg. daily was a lethal dose, when continued for 20 days; larger doses caused more rapid death, but a smaller one, 0·5 mg., only caused loss of weight. For rats a dose of 5 mg. daily was lethal, for guinea-pigs 40 mg., for cats 5 mg., and for dogs 5 mg. per kg. of body-weight, but for fowls 50 mg. had no ill-effect, and for axolotls a dose of 10 mg. was innocuous. At autopsy an enormously rich deposit of lime was found, particularly in the walls of the vessels, in the heart muscle, stomach wall, lungs, kidneys, and intercostal musculature. The large vessels and often the small ones, too, were converted into rigid tubes. The spleen was often markedly atrophic and the small intestine showed hæmorrhagic inflammation of the mucous membrane. The picture was thus one of severe vascular sclerosis, to which the other symptoms were regarded as secondary, and it varied in severity with the species of animal.

In discussing their results, the writers recall the well-known cholesterol sclerosis which can be induced in rabbits, experimentally after five or six months' feeding with a daily dose of at least 0·1 g. cholesterol daily. They state that a similar ergosterol sclerosis occurs after two to three months' feeding with non-irradiated ergosterol, while the sclerosis just described, due to feeding with irradiated ergosterol, is acute in eight to fourteen days. It is clear from their own experiments that the time which symptoms of sclerosis take to develop is inversely proportional to the dose. Unfortunately, the authors do not mention what was the dose of non-irradiated ergosterol to which they refer. This is important, for it must be remembered that when ergosterol is irradiated, it is not all immediately converted into vitamin D; a certain portion remains unchanged. In absence of further evidence, it is possible that the sclerosis which Kreitmair and Moll observed to develop in feeding large doses of irradiated ergosterol may be due to the unchanged ergosterol and not to the vitamin; but to whichever element the effect may be due, the fact remains that large doses of irradiated ergosterol are toxic. This need not, however, cause uneasiness. The authors point out how enormous is the toxic dose, relative to the known dose needed to cure rickets. For the rat, for instance, the toxic dose is greater than 1 mg., while the healing dose is 1/10,000 mg. If we calculate the toxic dose for a man on the basis of that for the cat, it is found that 100 mg. daily would be needed to produce ill-effects in man. According to A. Hottinger [3] (1927) only 5 mg. daily are needed to cure an adult human being suffering from late rickets, tetany, or osteomalacia. The risk of overdosage in an adult thus seems to be very small. Dr. H. Mackay pointed out in THE LANCET of May 5th (p. 924) that nothing was known as to the possible effect of overdosage in an infant, and recommended discretion in the use of antirachitic preparations. It is reassuring to learn that in animals the margin between therapeutic and toxic doses of vitamin D is so great, but the fact that definite pathological changes have been recorded lends point to her warning.

MINERVA.

THE twenty-ninth issue [4] of this admirable year book of the learned world follows the twenty-eighth, after an interval of less than two years. The time has been sufficient to expand the volumes, which are already rather stout to bear the name of the slim goddess of wisdom; and, as Dr. Gerhard Lüdtke expresses it, the abundance of material threatens to burst the bounds of a year book. In the last issue it was decided to print the names of the members of large scientific academies, and it is personal details of this kind which have increased the size of the volumes, to the great convenience of those who have to refer to them, as we are happy to testify. In the interval the publisher has issued a Minerva Index, containing all the scientific institutes mentioned in the year book arranged topographically, and this third volume will be issued later, bound up with the name-index of the two volumes now before us. The editor of the year book is following more and more the practice of making the entries in the language of the country concerned, so far as that language is of world-wide distribution. He justifies against all gainsayers his custom of keeping close to the current postal addresses of names and institutions, although the usual (pre-war) alternative names are given in print of similar size. An asterisk calls attention to information which has not been revised for this issue, and may therefore be somewhat behind the date of revision which, for the rest of the book, is Nov. 1st, 1927. Information regarding medical and technical societies in North America has again been extended, and a welcome innovation is the standardisation of Slavonic names by Dr. Kuziela. Dr. Lüdtke again acknowledges the editorial help of Dr. Friedrich Richter, and especially that of Frl. Chr. Pilger; their work must have been colossal. The first volume contains, as frontispiece, a portrait of the Spanish scientist, S. Ramon Cajal, and the second that of Dr. Krüsz, general director of the Prussian State Library.

[4] 2 Vols., 1457 and 1306 pp. Vol. 3 will contain 960 pp. Subs. price for the 3 vols M. 80, increased to M. 90 after full publication. Berlin and Leipzig: Walter de Gruyter and Co.

POST-GRADUATE MEDICAL STUDY IN PARIS.

THE Whitsuntide visit paid by the Royal Institute of Public Health to Paris hospitals, and its reception there, was an interesting gesture and counter-gesture which can hardly fail to have its effect on future medical relations between the two countries. The group itself was too large to organise for serious study. Some of the visitors, no doubt, did not aspire to anything more arduous than a cursory view of French medicine at its headquarters; but it was impossible for anyone who took part in the visit not to be impressed with the wealth of clinical material, with the vitality of the teaching staff, and with their ability to get through with the messages they intended to impart. Under such circumstances it is naturally the more dramatic and successful adventures of medicine which strike the eye than the patient and plodding work behind the scenes, but there is in Paris hospitals an ample background, and what was seen and heard was unlikely to suffer from the need for comparison and perspective. The language difficulty is not insurmountable; scientific talk is readily apprehended in any civilised tongue by those who know the elements of science, and everywhere, in theatre and lecture-room, the French voice and intonation were found to be well adapted for instruction. Paris hospitals, too, are organised in a way which surprises the Londoner. With one or two exceptions all of them are constituent parts of the Assistance Publique, and as such were being rebuilt and re-equipped, in accordance with a central plan, when the scheme was interrupted by the outbreak of hostilities in 1914. Some hospitals, like the Pitié, are now practically rebuilt; others, like the Salpêtrière, retain all their mediæval charm; while in many there is a piquant contrast between the new wards on the pavilion system and the old stone-work of the cloistered buildings. Another surprise to the Londoner is the spaciousness of the hospital grounds and the leafy verdure of the gardens as one passes from ward to ward, from theatre to laboratory. All the chief hospitals are situated within an easy tram or 'bus ride, almost within walking distance of the central school of medicine. The visit itself may be regarded as a reconnaissance rather than as a finished event, for among the party was a large sprinkling of recently qualified men and women on the look-out for opportunities of post-graduate study in some congenial direction. Four of the hospitals—Hôtel-Dieu, Pitié, Charité, Saint-Antoine—are organised specially for surgery, three others—Laënnec, Beaujon, Necker—for medicine, while obstetrical study centres at Baudelocque, Tenon, and Maternité, Beaujon being reserved for the instruction of midwives. In special subjects the ophthalmologist will turn to Hôtel-Dieu, the neurologist to Salpêtrière, the alienist to Sainte-Anne, the gynæcologist to Broca, the student of genito-urinary diseases to Necker. The Association for the Development of Medical Relations will offer any of these the information needed for choice and organisation of study. We shall return in more detail to the institutes visited, in the meantime warmly congratulating those who arranged the visit upon an event of some medical and international significance.

MATERNAL MORTALITY.

WHEN introducing the estimates of the Ministry of Health on May 15th, Mr. Neville Chamberlain [1] contrasted the decline of the death-rate among the population in general, and among young children, with the continuance of a high maternal mortality. He pointed out that out of every 250 mothers one died in childbirth—a state of things which had persisted for the last 20 years—and said that the time had come to make a "great new effort" to bring down these persistently high figures. That they are very far from irreducible will be evident to anyone familiar with the figures quoted in the discussion reported on p. 1178 of our present issue. After outlining a scheme by which local medical officers of health will inquire into the circumstances of every death during childbirth and practitioners will be asked to supply information to the Ministry, Mr. Chamberlain went on to announce the formation of a committee to consider the training and working conditions of midwives. We have already recorded [2] the terms of reference and membership of this committee, and need only recall that its medical members are Sir Robert Bolam (chairman), Dr. J. W. Bone, Dame Janet Campbell, Dr. W. A. Daley, Dr. J. S. Fairbairn, and Dr. F. N. Kay Menzies. Its appointment has now been closely followed by the establishment of a second Departmental Committee, which is "to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available, and to inquire into the needs and direction of further research work." Sir George Newman, the Chief Medical Officer of the Ministry, will be chairman, and the members, all of whom belong to the medical profession, are: Prof. F. J. Browne, Dame Janet Campbell, Mrs. Ethel Cassie, Dr. Leonard Colebrook, Prof. Archibald Donald, Dr. C. E. S. Flemming, Sir Walter M. Fletcher, F.R.S., Dr. Harold Kerr, Dr. W. H. F. Oxley, Prof. Miles Phillips, Dr. C. E. Tangye, and Dr. O. L. V. de Wesselow. The secretary will be Dr. Margaret Hogarth, to whom all communications relating to the work of the Committee should be addressed at the Ministry.

POST-OPERATIVE TETANUS IN SCOTLAND.

As an outcome of an inquiry into the occurrence of post-operative tetanus undertaken for the Scottish Board of Health, Prof. T. J. Mackie concludes that the manufacture of surgical catgut should be controlled by the Ministry of Health under the Therapeutic Substances Act. In collaboration with Dr. D. G. S. M'Lachlan, Prof. Mackie has prepared and published a report [3] which sets out the circumstances surrounding a series of 11 cases occurring in one institution, presumably in Scotland. The name of the institution is not revealed, nor the date of the so-called "recent cases," nor is there any indication in the terms of reference over what period the inquiry was pursued or when it was completed. All these details, which must have been deliberately omitted, would be of interest to readers of the report, though it cannot be said that any of them are directly relevant to the purpose of the inquiry, or that its scientific value is diminished by their absence. In official reports, however, it is customary for full information to be given, and public confidence is more likely to be enhanced than diminished by a documented account of untoward events, and of the steps taken to prevent their recurrence. It is at any rate satisfactory to be assured that the last case of the series occurred over a year ago. After 4 cases of tetanus and 1 of gas gangrene had been reported within six weeks, the particular supply of catgut was stopped "and during the succeeding 12 months (up to present date) no further cases" were reported. From the schedule in which details of the 11 cases are tabulated, it appears that nine developed tetanus, one gas gangrene, and one a sporing anaerobe infection with muscular spasms, of which the organism was not demonstrated to be tetanus. The incubation period varied between 7–12 days, except in the case of gas gangrene (two days), and in the non-fatal cases of tetanus (14 days). Six of the cases were gynæcological, five being repair operations. Catgut from the same source was used in all cases. Five occurred in one theatre, the rest being distributed over different theatres; the operations were performed by ten different surgeons. The technique of sterilisation in

[3] An Inquiry into Post-Operative Tetanus. Report to Scottish Board of Health. 1928. H.M. Stationery Office. Pp. 62. 1s.

the various theatres was inquired into and appeared to be highly efficient. The question of auto-infection was considered and not definitely excluded, but in view of the fact that other inquiries pointed so definitely to an external source of infection, it was not pursued.

Prof. Mackie gives numerous references from recent medical and surgical literature to records of cases of post-operative tetanus; in many of these catgut was considered the most probable cause. The fact that the tetanus bacillus occurs as a commensal organism in the intestinal tract of various herbivorous animals suggests that surgical catgut, which is prepared from sheep's intestines, must be regarded as a potential source of the organism. The anaerobic sporing bacilli produce highly resistant spores, capable of withstanding physical and chemical agencies which kill non-sporing organisms, and, moreover, spores deeply embedded in the substance of a catgut string may be protected from germicidal agents which would otherwise destroy them. The incidence of post-operative tetanus in the particular institution with which this inquiry was concerned was peculiar in that a series of cases occurred within a limited period. During this period the institution was supplied with surgical catgut almost entirely from one source, mostly in the form of "dry strings" which had already undergone processes of sterilisation in their preparation from raw material, but were not guaranteed as free from surface contamination; before surgical use they were subjected to further bactericidal treatment.

The relation of contaminated catgut to post-operative tetanus and gas gangrene was studied experimentally by Prof. Mackie and Dr. M'Lachlan, and also the resistance of bacterial spores to physical and chemical agencies, with special reference to the sterilisation of catgut. Specimens of the catgut were taken at various stages of preparation and were examined for tetanus and allied bacilli. In a considerable proportion of specimens from different sources sporing anaerobic bacilli related to *B. tetani* were found, and from one specimen *B. tetani* was actually isolated after the catgut had been treated by the routine bactericidal processes and had been stored in a stoppered bottle ready for use. Prof. Mackie and his colleague came to the conclusion that certain of the sterilisation processes relied on in the preparation of catgut were not efficacious. Amongst the various agents tested they found the most effective and practicable to be iodine in a watery solution, and hydrogen peroxide. These processes should, however, be controlled by bacteriological tests on samples from each batch. It must be remembered that the presence of B. *tetani* in raw material may be highly variable; certain batches only may be contaminated, and, moreover, bactericidal processes, even if not entirely effective, may have destroyed the majority of spores. The survivors may be extremely scanty and irregular in their distribution in the catgut strands, and the thickness of certain strands may protect them from destruction. These considerations may account for the infrequency of cases relative to the total number of operations carried out in which catgut was used. The possibility that primary sepsis in an operation site may be a predisposing factor in the development of post-operative tetanus receives some support from this investigation. In any case there seems no doubt, in view of the difficulties of eliminating sporing organisms from this material and the inefficacy of various methods which have been relied on for this purpose, that the manufacture of surgical catgut should be subjected to more rigid control.

Two donations of £50,000 each have been made to the Royal Free Hospital, London, by Lord Riddell and Mr. Alfred Levy, the President and Treasurer of the hospital. These sums were guaranteed some time ago in order to secure a gift of £200,000 from Mr. George Eastman, which is to be used for the foundation of a dental clinic. This clinic will be started on the same lines as one established by Mr. Eastman at Rochester, U.S.A.

THE Samuel Augustine Courtauld Institute of Biochemistry at the Middlesex Hospital will be opened at 3.30 P.M. on Thursday, June 14th, when Sir Archibald Garrod will give an address on the Place of Biochemistry in Medicine. We are asked to say that former students of the hospital will be admitted on presentation of their card.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 26TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 258 (last week, 336); scarlet fever, 1575; diphtheria 1044; enteric fever, 53; pneumonia, 1192; puerperal fever, 50; puerperal pyrexia, 91; cerebro-spinal fever, 5; acute poliomyelitis, 2; acute polio-encephalitis, 2; encephalitis lethargica, 27; typhus fever, 2; continued fever, 2; dysentery, 12; ophthalmia neonatorum, 107. No case of cholera or plague was notified during the week.

The cases of small-pox were notified from the following 27 counties: London, 5; Bedford, 6; Chester, 1; Derby 3; Devon, 3; Durham, 50; Gloucester, 6; Hertford, 4; Kent, 1; Lancaster, 12; Leicester, 5; Lincoln, parts of Holland, 2, parts of Kesteven, 2, parts of Lindsey, 4; Middlesex, 1; Norfolk, 5; Northampton, 1; Northumberland, 24; Nottingham, 9; Stafford, 22; Surrey, 2; Sussex East, 1; Warwick, 10; Yorks, North Riding, 6; West Riding 44; Glamorgan, 8; Monmouth, 21. It is noteworthy that although the disease is so widespread the total number of cases reported is not increasing.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on May 29–30th was as follows: small-pox, 25; scarlet fever, 1679; diphtheria, 2059; enteric fever, 27; measles, 999; whooping-cough, 147; puerperal fever 15 (plus 13 babies); encephalitis lethargica 69; poliomyelitis, 1; "other diseases" 29. At St. Margaret's Hospital there were 15 cases of marasmus, and 10 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1 from enteric fever, 51 (26) from measles, 4 (1) from scarlet fever, 42 (13) from whooping cough, 40 (11) from diphtheria, 37 (6) from diarrhœa and enteritis under two years, and 74 (22) from influenza. The figures in parentheses are those for London itself.

The fatal case of enteric fever outside London occurred at Salford. Of the 25 fatal cases of measles outside London 9 were reported from Liverpool and 3 from Middlesbrough. Of the 29 fatal cases of whooping-cough outside London 9 were reported from Birmingham and 5 from Liverpool. During the same week 9 deaths from whooping-cough were reported from Glasgow.

The number of stillbirths registered during the week was 317 in the great towns (corresponding to a rate of 44 per 1000 births) including 53 in London.

The death assigned to small-pox at Bradford in the return for the week ended May 12th was, we learn from Dr. J. J. Buchan, that of a man, 46 years of age and unvaccinated, admitted in an extremely emaciated condition, to the small-pox hospital from the Bradford Municipal Hospital where he had been a patient since October last, suffering from neoplasm of the lung. The small-pox was of confluent type and probably only shortened his life by a few weeks, the primary cause of death being neoplasm of the lung.

The Cases of Typhus Fever.—Two cases of typhus notified in the Metropolitan Borough of Stepney were those of a tailor's machinist, aged 48, admitted to St. Peter's Hospital, Whitechapel, on April 30th with a diagnosis of influenza, and his wife, aged 51, admitted on May 30th. In the man's case pyrexia and continued headache were followed by a state of complete apathy in which the development of a petechial rash suggested the need for special tests when both the Weil-Felix and Wassermann reactions were found to be positive. In the woman's case the temperature fell by lysis and rash was absent, although delirium persisted; positive findings of Wassermann and Weil-Felix assured the diagnosis and resulted in

her transference to the M.A.B. Hospital on June 2nd. Dr. A. Randle and Dr. C. Marian have kindly supplied clinical histories of these two cases, embodying a number of interesting features, which we hope to publish next week. A case of typhus notified in the urban district of Herne Bay was, we learn from Dr. A. M. Watts, that of a patient residing in a neighbouring rural district. There is, he adds, some doubt as to the diagnosis, although the clinical condition justified the notification.

A Small Epidemic of Typhoid at Bath.—As will have been seen from our summary of the Weekly Returns a number of cases of typhoid fever have been notified from Somerset during April and May. Twenty-six of these cases have occurred in an outlying part of the city of Bath, known as Bathwick, situate too high on the hillside to be reached by the ordinary water-supply of the city. It is now regarded as probable that the outbreak has been due to the pollution by a faulty drain of the highest of three water tanks on the hillside, as there has been no evidence of further infection since this drain has been put right. The last case, notified on June 4th, was that of a patient who had been under suspicion for ten days, and we understand that Dr. J. F. Blackett, the medical officer of health, regards the epidemic as over. Unfortunately, two of the cases have proved fatal.

MEMORIAL FUND TO SIR DAWSON WILLIAMS.

SINCE the first list was published in these pages subscriptions have been received from the following.

LIST OF SUBSCRIBERS.

A.—Dr. Peter Abercrombie; Dr. Theodore Dyke Acland; Dr. C. J. H. Aitkin (Kilnhurst); Dr. A. Gunn Auld.

B.—Dr. Bernard Batt (Bury St. Edmunds); Dr. A. T. Bazin (Montreal); Major-Gen. Sir Alfred Blenkinsop (Frensham); Mr. C. J. Bond, F.R.C.S. (Leicester).

C.—Dr. J. N. Cameron (Toronto); Dr. Wayland C. Chaffey (Hove); Dr. David Clow (Cheltenham); Dr. Alice Sanderson Clow; Dr. T. T. Cockill (Milford); Sir W. Collins, F.R.C.S.; Dr. Sidney Coupland (Oxford); Lt.-Col. D. G. Crawford, I.M.S. (Ealing); Prof. J. R. Currie (Glasgow); Mr. H. Morriston Davies, F.R.C.S. (Ruthin); Dr. W. F. Dearden (Old Trafford); Dr. Henry Devine (Virginia Water).

E.—Col. R. H. Elliott, F.R.C.S.

F.—Dr. Thomas Fawsitt (Oldham); Mr. H. N. Fletcher, F.R.C.S.; Dr. Louise Fraser (San Remo, Italy); Prof. Andrew Fullerton, F.R.C.S. (Belfast).

G.—Dr. R. P. Garrow (Chesterfield); Dr. R. A. Gibbons; Dr. F. W. Goodbody; Dr. T. A. Goodfellow (Manchester); Mr. Gordon Gordon-Taylor, F.R.C.S.; Dr. W. Gosse (Parkstone); Dr. A. E. Gow; Mr. A. M. H. Gray, F.R.C.S.

H.—Mr. C. D. Hamilton, M.R.C.S. (Athens); Dr. C. B. Heald; Dr. W. E. Hempson (Tunbridge); Mr. E. E. Hughes, F.R.C.S. (Manchester); Dr. W. Hunter.

J.—Dr. A. J. Jex-Blake (Nairobi).

K.—Prof. Mary F. Lucas Keene; Dr. Lawrence Kilroe (Rochdale); Dr. V. Ridman King (Swindon).

L.—Dr. E. E. Laslett (Hull); Dr. R. D. Lawrence; Dr. T. W. P. Lawrence (Tadworth); Dr. A. A. Lendon (Adelaide); Sir John Lynn-Thomas, F.R.C.S. (Llechryd).

M.—Lt.-Colonel R. and Mrs. McCarrison, (Coonoor, India); Dr. S. Morton Mackenzie (Dorking); Dr. Elizabeth McVail; Sir Philip Magnus, Bt. (Chilworth); Lady Mott (Bournemouth).

N.—Mr. H. W. Nott, M.R.C.S. (Guildford).

O.—Dr. Joseph O'Connor (Woking); Lt.-Col. F. O'Kinealy; Mr. Robert Ollerenshaw, F.R.C.S. (Manchester).

P.—Dr. George Parker (Clifton); Mr. Norman Patterson, F.R.C.S.

R.—Mr. H. H. Rayner, F.R.C.S. (Manchester); Mrs. Sophia Richardson, M.D. (Cheltenham).

S.—Dr. D. W. Samways (Mentone); Dr. S. Gilbert Scott; Dr. W. W. Shrubshall (Brighton).

T.—Dr. Edward Thompson (Omagh).

W.—Dr. Chalmers Watson (Drem, East Lothian); Dr. W. Watkins-Pitchford (Bridgnorth); Dr. G. N. Wauchope (Hove); Dr. J. W. Weir (E. London, S. Africa).

Incorrectly entered in previous list.—Mr. Eric Watson-Williams, F.R.C.S., should read Dr. Patrick Watson-Williams.

Those who may have overlooked the matter are invited to send their subscription before Saturday, June 16th, when the list must be definitely closed. The organising committee will then draw up recommendations for the disposal of the fund, and all subscribers will shortly afterwards be requested to attend a meeting to consider them. The hon. treasurer is Sir StClair Thomson, 64, Wimpole-street, W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXIX.—THE AMBULATORY TREATMENT OF VARICOSE VEINS.

I.* GENERAL CONSIDERATIONS AND TECHNIQUE.

THE results obtained in the treatment of varicose veins by means of injections show this method to have a permanent place as a therapeutic measure. Many different substances are in current use as intravenous sclerosing agents, but the object of all of these is the production of a phlebitis in the vein wall. This phlebitis is primarily either physical or chemical, depending upon the agent employed. A gradual thrombosis of the vein occurs; this is followed by organisation and eventually fibrosis of the thrombus, leaving a thin fibrous cord in place of a dilated and tortuous vein. The treatment is throughout ambulatory and need in no way interfere with the patient's work or recreations. Considerable discussion has recently centred around questions of technique, notably the nature and amount of the substance injected, the posture of the patient, and the use of a tourniquet. The method is not yet old enough to have become stabilised in detail; but the technique set out below has proved convenient and easily workable. With the exception of patients in whom contra-indications exist, the method is applicable to all cases of varicose veins, even in old patients or in the presence of complications such as dermatitis or ulceration.

The Circulation in Varicose Veins.

A considerable body of evidence both clinical and experimental goes to show that there is marked abnormality of the venous circulation in varicose conditions. On the whole, this evidence suggests that in patients with severe varicosity of the internal saphenous vein and in whom the Trendelenburg sign is positive, the blood flow in this vein is directed away from the heart when the patient is in the upright posture, but if the limb be raised to 45° or higher the flow is either stationary or sluggishly towards the heart.

Experimentally, this has been shown by the use of the hæmadromometer and by radiographic studies. That there is similarly a reversal of the blood flow in the skin capillaries of the leg under these conditions has been shown by Magnus using the skin microscope. In severe varicose states, therefore, the blood coming from the deeper parts of the limbs passes upwards in the femoral vein, reaches the level of the saphenous opening, and a certain amount of it passes into the internal saphenous vein and travels distally along this. From the lower part of the saphenous vein area the blood returns to the deeper system either by way of anastomotic veins, or after having passed through the capillary bed once more, in a reverse direction. Under these conditions certain areas of skin will be supplied with blood which has already once circulated through the capillary bed. These factors of the venous circulation are of fundamental importance in the development of varicose dermatitis and ulceration, in their chronicity and their resistance to purely local treatment.

This theory of the venous circulation is supported by clinical observation of the conditions under which varicose ulcers may be cured. Healing may be attained by adequate rest, by bandaging the affected limb to secure competent valve action of the veins, by surgical extirpation of the diseased veins, or by their intravenous thrombosis. All of these methods lead to the breaking of the vicious circle which permits of venous stagnation and capillary reversal.

* Part II., dealing with Reactions, Complications, and Results, will appear in our next issue.

The varicose ulcer results primarily from malnutrition of certain areas of skin due to the mechanics of the circulation in varicose conditions, and its prophylactic treatment lies in the cure of uncomplicated varices.

The Histology of Thrombosis.

The processes occurring in the vein wall and its lumen following intravenous sclerosing injections have been studied experimentally, both in man and in animals, by removing portions of veins at varying intervals afterwards. These studies all show that in response to the irritation of the injected fluid a chemical phlebitis of the vein wall occurs, leading to the production of a firm, adherent thrombus over the affected segment. There is considerable swelling of the wall of the vein and proliferation of its cell elements, and this is rapidly followed by organisation of the thrombus. The fibrosis, however, may take three months to become completed. The thrombosis of the vein occurs in response to the very active changes occurring in the vein wall, and at no stage whatever is the thrombus soft or loosely attached. For these reasons detachment of a portion of the thrombus with all its attendant risks becomes a very remote possibility.

The Quinine-urethane Method.

Many different solutions can be employed to produce thrombosis in varicose veins. The one about to be described was introduced by Génévrier, and gives very good results.

Quinine Hydrochloride, 4 g.; urethane, 2 g.; aq. dest., ad 30 c.cm.

The solution is made up in small rubber-capped vaccine bottles and is then sterilised by boiling. As some of the quinine salt crystallises out on cooling, the bottles should be allowed to stand in warm water for a few minutes before use to redissolve this.

Technique of Injections.

The technique I employ is as follows:—

With the patient standing an Esmarch's tourniquet is applied, proximal to the proposed site of injection. The only object in applying the tourniquet is to render the veins prominent during the actual insertion of the needle into the lumen of the vein, and in all cases it should be removed before the injection is given. The patient then lies down and the area of proposed injection is thoroughly cleaned with spirit. The needle of a 5 c.cm. syringe containing the quinine-urethane solution is introduced obliquely through adjacent healthy skin into the lumen of the vein it is desired to thrombose. The plunger is slightly withdrawn to confirm the correct position of the needle, and the tourniquet removed. The injection is then slowly given at the rate of 1 c.cm. in 15 seconds. The object of removing the tourniquet before giving the injection is to have the vein in as collapsed a state as possible during the injection, and to ensure the quinine-urethane solution reaching the vessel walls in a high concentration. The needle is withdrawn and firm digital pressure applied with a sterile swab at the site of injection for about two minutes. A small collodion dressing on wool is then applied and when dry the area is firmly bandaged. The maintenance of digital pressure after injection, followed by bandaging, is designed to lessen the risk of leakage of blood mixed with the injection material into the tissues around the site of puncture. Should this occur local complications may follow. The patient is allowed to proceed home and to carry on with his normal activities. Rest is never enjoined but the patient is always warned of the reactions which follow injection. He returns for further treatment at the end of a week.

Dosage.

In using the quinine-urethane method it is always advisable to commence injections with a very small dose. The one usually employed is ½ c.cm. The object of this is to test, firstly, the local reaction of the veins to the solution; and, secondly, the patient's sensitivity to quinine, though it is exceptional for any general reaction to occur in the doses customarily given. After the first injection larger doses may be used, but never more than a total of 4 c.cm. at any one sitting. The injection may be given in amounts of 1 c.cm. or more at various sites, but as a rule not more than 3 c.cm. should ever be given at one site. In the majority of cases an injection of 1 c.cm. will be found sufficient to thrombose an area of about 2 inches on either side of it. But it should be borne in mind that no two cases react exactly alike, and decisions as to dosage must be influenced by the degree to which thrombosis is produced.

Site of Injection.

The first injections should always be made in the most distal part of the affected area and each succeeding injection should be made proximal to it. This enables the operator to distinguish easily veins which are still patent from those which are thrombosed. In the majority of cases, therefore, the injections will begin on the inner side of the lower third of the leg. If, however, the varicose condition involves the inner side of the foot and the region of the internal malleolus, these sites should not be injected at the commencement of the treatment; after the course the veins will probably be found to be much smaller in size and as a rule give rise to no further symptoms. Should it be decided to inject these areas, however, it is as well to bear in mind that the pressure of boots and shoes is likely to cause some discomfort whilst thrombosis is proceeding.

The whole of the saphenous tract may be treated to within 4 inches of the saphenous opening.

REGINALD T. PAYNE, M.B., B.S., F.R.C.S. Eng.,
Chief Assistant to a Surgical Unit, St. Bartholomew's Hosp.; Registrar, Royal National Orthopædic Hosp.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lts. R. W. Higgins to *Tamar*, for R.N. Hospl., Hong-Kong; and D. R. Campbell to *Impregnable*, temp.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. H. E. Hall to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS,

Maj. C. R. Millar to be Lt.-Col.

Maj. B. Varvill retires on retd. pay.

Capt. T. H. Twigg to be Maj. (Prov.) and remains secd.

Temp. Capt. J. W. Pell relinquishes his commn. and resumes the rank of Capt.

Temp. Lt. J. D. Cooper relinquishes his commn.

ARMY DENTAL CORPS.

Capt. P. E. Jessop, late T.A. Res. of Off., to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

General List: Maj. J. H. Donnell, having attained the age limit, relinquishes his commn. and retains his rank.

General Hospitals: Capt. W. Seymour, having attained the age limit, relinquishes his commn. and retains his rank.

Hygiene Companies: Capt. D. Smith, having attained the age limit, relinquishes his commn. and retains his rank.

ROYAL AIR FORCE.

The undermentioned Flying Officers are promoted to the rank of Flight Lt.: P. H. Perkins and S. F. Heatley.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. F. K. Wilson is transferred from Class D (ii) to Class D (i).

INDIAN MEDICAL SERVICE.

Capts. Munguldas Tuljaram Khandwala, J. Rodger, and Ghulam Ahmad Khan to be Majs.

Capt. R. T. W. Stoney retires, receiving a gratuity.

Special Articles.

FOOT-AND-MOUTH DISEASE IN MAN.

By J. A. ARKWRIGHT, M.D., F.R.C.P., F.R.S.,
ASSISTANT BACTERIOLOGIST, LISTER INSTITUTE, LONDON.

ALTHOUGH the occurrence of foot-and-mouth disease in man has lately been mentioned in the daily press as a definite risk, human cases are rarely heard of nowadays, and it is doubtful how many of those formerly so described were really due to this cause.

During the latter half of the nineteenth century, when the disease was very prevalent in our flocks and herds, many cases of stomatitis in man, sometimes accompanied by vesicles on the hands, were attributed to the same infection. Some of the human patients had been in contact with diseased cattle, but most of them were believed to have been infected by drinking their milk. The transmission from man to man has only rarely been suspected. In some of the years during that epizoötic period not only was the total number of animals attacked very large, but the number which were sick at the same time must have been very great, since slaughter was not adopted as a general policy.

In 1869 A. McBride recorded a number of cases in man collected from 22 different sources. All these he regarded as undoubted infections with foot-and-mouth disease. In some instances several members of one household were affected. Of four cases of vesicular stomatitis which he observed himself three occurred in one family after drinking the milk of cows suffering from the disease; the fourth, a butcher, appeared to have directly inoculated his mouth by holding an infected knife between his lips. In the same year Dr. Thorne Thorne investigated an epidemic of stomatitis the distribution of which was associated with the milk-supply. He inclined to the view that the infection was derived from cattle suffering from foot-and-mouth disease. In 1884 an epidemic of severe vesicular tonsillitis and enlarged glands occurred at Dover. In this outbreak also infection by the milk of cows suffering from foot-and-mouth disease was suspected. About the same time a smaller outbreak attributed to a similar cause was reported from Norfolk; the patients were children, and two of them died. Cases of foot-and-mouth disease occurring singly or in groups have often been described on the Continent. In 1896 Bussenius and Siegel collected records of over 1500 supposed cases of this disease in human beings including 600 which had recently occurred in Prussia.

The real nature of many of these outbreaks, however, was disputed at the time and subsequent experience has suggested that cases of sore mouth and throat and of pustular eruption due to other causes have often wrongly been accepted as manifestations of foot-and-mouth disease in human beings. Epidemics of fever and tonsillitis due to streptococci, in which the infection is spread by milk, are now well known and not infrequently the infection has been traced to cows with inflamed udders. Moreover, since milch cows attacked with foot-and-mouth disease often suffer from mastitits due to secondary infection with streptococci and other bacteria, it seems probable that some of the milk-borne epidemics referred to above were due to bacterial infections and not to foot-and-mouth disease.

Transmission to Man.

In 1921 Lebailly investigated ten cases of aphthous stomatitis, believed to be foot-and-mouth disease, which were attributed to drinking infected milk. He made three attempts to transfer the infection from man to cattle without success. He also tried three times to transmit foot-and-mouth disease from cattle to man, but with negative results. Lebailly accordingly expressed his doubts as to the possibility of the transmission of foot-and-mouth disease to man. But in spite of this and other adverse criticism, which has been in part a reaction against the former too ready belief in human susceptibility to foot-and-mouth disease, there can be little doubt that this disease has occasionally been transmitted to man. For instance, the case is recorded of a veterinary surgeon who accidentally infected himself from an animal which he was examining and had five vesicles on the lips and tip of the tongue, and some of the cases related by McBride appear to be based on equally good evidence. In three or four instances the diagnosis has been confirmed by the re-infection of animals from man. Schautze in 1893 described a case of foot-and-mouth stomatitis in man from which he successfully inoculated two calves. Bertarelli, in 1908, recorded two human cases acquired by direct contact with animals; in both there were large vesicles in the mouth and on the lips. With vesicular fluid from one patient he obtained typical vesicles on the ear and lip of a calf. Favero also is said to have successfully inoculated a calf from a human case in 1914. It must, however, be remembered that vaccinia and herpes labialis and some lesions due to coccal infections are also transmissible to animals and vice versa.

Comprehensive and critical reviews of all available records of reputed foot-and-mouth disease in man are to be found in the papers by Cadiot (1914) and by Gins and Krause (1924). The diagnosis of foot-and-mouth disease in man can only be conclusively established by producing in a susceptible animal local and generalised vesicles recognisable by one familiar with the disease, and by showing that immunity to the same type of foot-and-mouth disease results. These criteria have never been satisfied, but no doubt can reasonably attach to the two following records of foot-and-mouth disease in man:—

Pape, who with Waldmann in 1921 discovered the method of infecting guinea-pigs with foot-and-mouth disease, cut his thumb with a broken glass vessel whilst collecting virus from a pig. Two days later he had slight headache and shivering. On the third day vesicles began to develop on the palms and soles and continued to appear at these sites, but not elsewhere, for two days. There were 25 vesicles in all varying in size from a flax-seed to a cherry-stone. They contained clear fluid and rapidly healed without suppuration. The only buccal lesion was a slight swelling and tenderness on the gum on one side at the time of the cutaneous eruption. This occurrence was before the discovery of the susceptibility of guinea-pigs and no animals were inoculated, but Pape, when later inoculated with foot-and-mouth virus, proved to be immune.

In 1922 several cases of vesicular stomatitis, sometimes with vesicles on the hands also, occurred in the province of Como, where there was an epizoötic of foot-and-mouth disease. Clear fluid from the vesicles of one of these patients with bullous stomatitis was taken to Milan and inoculated by Pancera into guinea-pigs and a calf, all of which developed typical lesions.

Diagnosis of the Disease.

The important points in clinical diagnosis in man in the present state of knowledge appear to be initial fever and superficial vesicles containing clear fluid on the lips and buccal mucous membrane, with perhaps vesicles on the flexor aspects of the hands and feet. Both the incubation period and the period of fever and eruption are short, not exceeding three or four days each. An exact and detailed account of more cases whose diagnosis is incontrovertible is very much needed. Sometimes cases have been described as foot-and-mouth disease in man in which besides stomatitis a skin eruption has occurred on the lower legs, forearms, and backs of the hands and has especially affected the beds of the nails, causing the latter to be deeply grooved or even shed. There does not seem to be any experimental evidence confirming the diagnosis in such cases and in Pape's case the skin lesions were confined to the palms and soles as is also the case in guinea-pigs. It is questionable whether the diagnosis can certainly be made at the present time without animal experiment, especially where infection by milk is suspected. Such an investigation can only be carried out in this country with the special sanction of the Ministry of Agriculture.

THE POSITION OF VOLUNTARY HOSPITALS.

A SURVEY OF PROGRESS.

THE final report [1] of the Voluntary Hospitals Commission, issued last week, opens with an expression of regret at the death of Sir Robert Hudson who had been a member of the Commission since its first appointment. The remaining members of the Commission are the Earl of Onslow (chairman), Sir Robert Bolam, M.D., Sir John Rose Bradford, M.D., Dr. R. C. Buist, Lord Clwyd, Mr. H. Wade Deacon, Major W. E. Elliot, M.B., Sir George Makins, F.R.C.S., Mr. D. O. Malcolm, Dr. F. N. Kay Menzies, Sir E. Cooper Perry, M.D., with Mr. L. G. Brock (secretary), and Mr. P. Barter (assistant secretary). Owing to his absence in India, the Marquess of Linlithgow was unable to take part in the Commission's deliberations on the present report.

The Previous Report.

In the report [2] of July, 1925, was set out the result of an inquiry into the extent of the additional voluntary hospital accommodation required in England and Wales, and the best means of providing and maintaining it. As the result of a survey of the existing hospital accommodation, carried out with the assistance of the local voluntary hospital committees, the conclusion was reached that, owing to the inability of the hospitals to undertake extensions during the war and for some considerable period afterwards, the accommodation was short by 10,000 beds of what was required to provide a reasonable standard of adequacy. In arriving at this figure, regard was had to the number of additional beds which it was reasonably probable the hospitals could maintain, assuming that the funds for necessary capital expenditure could be found. The information then collected by the Commission satisfied it that the shortage of bed accommodation then existing was causing much avoidable suffering, as was evidenced by the very large number of persons who were reported to be waiting admission to hospitals. The situation disclosed by the survey was regarded as grave and certain to prejudice the future of the voluntary system.

Refusal of a Government Grant.

The present report recalls that early in 1926 the Commission was informed by the Minister of Health that the financial situation of the country was such as to make it impracticable at that stage to proceed with the proposals for a grant from public funds towards the cost of new construction on the lines of its recommendations. Its main task having been accomplished, the work of the Commission is now being laid down, with a regret that it has been impossible to implement proposals to which so much time and thought have been devoted. In the absence of any prospect of a Parliamentary grant, the Commission concludes its work by summarising the position as it exists at present in comparison with that disclosed by the survey of 1924.

Extension of Accommodation.

Without some assistance from public funds it was not to be expected, the Commission states, that rapid progress would be made. The figures for 1927 are not available, but statistics given in an appendix prove that during this period of 2½ years the hospitals have shown marked activity in the matter of extensions, and during the latter part of that period the rate of expansion has considerably exceeded the provision required to keep pace with the growth of the population, with the result that the arrears of the war period are being gradually, but appreciably, reduced. Speaking generally, this expansion has been more rapid and more widespread than was anticipated.

In comparing the new figures with those given in a previous report, it is necessary to make allowance for the growth of the population, and the excess of bed accommodation available at the end of December, 1926, over the corresponding figures for June, 1924, must not be taken as representing a net gain. At the time of the 1924 survey the ratio of beds to population was 1·33 per 1000. This ratio, however, was based upon a figure of accommodation which, in our opinion, was 10,000 beds short of what was reasonably necessary. If this deficiency had not existed the ratio of beds to population would have been 1·6 per 1000, and this represents the rate at which the hospitals must expand to keep pace with the growth of population. The increase in population in the 30 months between the date of the 1924 survey and the end of 1926 is estimated at approximately 638,000. On the basis of 1·6 beds per 1000 it was necessary, therefore, for the hospitals to provide 1020 beds to meet the increase in population.

The returns received from local voluntary hospital committees, including King Edward's Fund (which acts as the local committee for London) show that in this period 3829 beds were actually provided, or 2809 more than the number required to meet the growth of population. The reduction of the arrears to this extent in 30 months represents an average reduction at the rate of 1124 beds per annum. In fact, however, the expansion has not been spread evenly over this period, and as the rate of increase in 1926 has been appreciably higher, the Commission hopes that the top of the curve has not yet been reached.

These figures naturally suggest the question as to how far this rate of progress can be regarded as satisfactory. It is admittedly less than is ideally desirable, but, on the other hand, it is considerably better than the Commission had reason to anticipate in framing its last report. Taking as the test, not the actual number of beds added, but the amount of money becoming available for new construction, the position appears still more hopeful. In London the receipts for building purposes amounted in 1925 to £735,000, and in 1926 to £479,000, as compared with an average of £308,000 for the three years 1922–24. It is recognised that the position for London does not necessarily reflect the position of the country generally, owing to the fact that King Edward's Hospital Fund tends to attract special benefactions, and it has, in fact, received several unexpectedly large bequests during this period. But, though figures for the provinces are not available, there is ground for believing that the amounts appropriated for building purposes have substantially increased, and we may reasonably expect a further improvement in the rate of progress.

Funds for Maintenance.

Information which has become available since the previous report confirms the Commission's view that there is no ground for apprehension as to the ability of the hospitals to provide funds for the maintenance of the additional beds. Thus, although in 1925 a substantially larger number of beds had to be maintained than in the previous year, the excess of income over expenditure amounted to as much as £734,000, or over £100,000 more than in 1924. Owing chiefly to the industrial conditions prevailing in 1926 the financial position in that year was less favourable than in 1925, but with the return to more normal conditions we are confident that the position will again improve. If the hospitals had been faced with these conditions in 1921 or 1922 they would probably have suffered irreparable harm, and the success with which the hospitals met this crisis indicates the extent to which the financial structure of the system has recovered from the strain of the war period. But, although in the aggregate a deficit has not been experienced since 1922, there are still areas in which the income of the hospitals is insufficient to meet the expenditure, and in which for this reason

Foot-and-mouth Disease in Man.

(*Continued from previous page.*)

References.—McBride, A.: Brit. Med. Jour., 1869, ii., 536. Cadiot: Rec. de Méd. Vétér., 1914, xc., 296. Gins, H. A., and Krause, C.: Ergebniss. d. allgem. Path. u. pathol. Anatom., München, 1923–24, xx., 2 Abt., 805.

t has not yet been possible to undertake extension on an adequate scale. These areas comprise some of the most important hospital centres in the country. Indeed, it is the large general hospitals with medical schools attached in which the costs of maintenance are higher than in other hospitals, which find the greatest difficulty in collecting the funds necessary for carrying on the ordinary work of the hospital to the fullest extent. Failure to solve the problems of maintenance and extension in those areas cannot fail eventually to react to the prejudice of the voluntary system.

Mass Contribution.

It is noticeable, the report continues, that in certain areas where recovery has been most marked some system of mass contribution has been established. In reviewing the sources of income upon which the voluntary hospitals can rely, receipts from legacies are necessarily a problematical element. As regards subscriptions, some few hospitals have received princely benefactions from individual contributors; but the percentage of income derived from large subscriptions is scarcely likely to increase. The interest of the middle-class subscribers has been, the Commission thinks, remarkably well maintained, having regard to the fact that the proportion of these subscribers who benefit directly from the existence of the voluntary hospitals is comparatively small. But it would be a mistake to look for a considerable increase of income from this source. The only quarter whence any substantial growth of income may be looked for in future would be from contributions from the industrial classes. The permanence of the voluntary system depends upon its ability to meet the needs of the people, and nothing is so certain to imperil its continuance as the growth of long waiting-lists. Excluding London, whose position as the consultant centre for much of south-east England is quite exceptional, most of the hospitals which are prosperous and which are keeping pace with the growing demands upon them are those which draw revenue from mass contribution schemes.

The Commission therefore reiterates its conviction that the future of the voluntary system depends in a large measure on its success in securing in one form or another the continued support of the small contributor. It must be recognised, however, that the framing of any scheme of mass contributions calls for the exercise of great care to avoid the acceptance by the hospital of liabilities which cannot be discharged, or the creation in the minds of contributors of expectations which may not be fulfilled. At the same time the effect of such scheme upon the government of the hospital and the relations of the medical staff must also be taken into consideration. It is hoped that those local voluntary hospital committees which have not turned their attention to this problem will make a real effort, in conjunction with hospitals, to establish, under adequate safeguards, such schemes wherever circumstances permit. Heretofore this conclusion has not been pressed upon local committees because of the manifest risks and difficulties which the system entails. But the experience of recent years has convinced the Commission that this is the main source of new income, and while the dangers are real the Commission does not believe them to be insuperable.

Local Voluntary Hospital Committees.

The local committees instituted on the recommendation of Lord Cave's Committee to facilitate the distribution of the Government grant are nearly all still in existence, but their activities vary. Those in the large centres of population are the most prominent, and in many places have filled an important part in the local health machinery. In country districts the committees are less active owing to the opportunities of service being less numerous, but they remain in existence ready for work if called upon. The Commission expresses its indebtedness to the valuable information submitted to them by the committees in reply to their inquiries for much that is contained in the present report.

A Statistical Survey.

In an appendix to the report is a comparative statement of voluntary hospital accommodation at the date of the Commission's survey in 1924 and at Dec. 31st, 1926.

Hospitals and Motor Accidents.

The Commission agrees with the view expressed by many authorities that the increasing frequency of motor accidents is placing a heavy burden on many hospitals. This charge ought not, it thinks, to fall upon funds derived largely from the generosity of the charitable, whose gifts are intended for the relief of persons who have not the means to provide institutional treatment at their own cost. While the possession of a motor is very far from being evidence of affluence, those who can afford to maintain a car would suffer no hardship if by some system of

compulsory insurance they were required to pay the premium, probably comparatively small, which would be needed to cover the treatment of their own injuries as well as those which may be caused to others. The incidence of this burden is very unequally distributed, and it falls with special severity on the hospitals which are situated on or near those new roads whose excellence from an engineering point of view affords a seemingly irresistible temptation to excessive speed. The proposal would involve legislation, possibly of a controversial character, but the Commission can see no other way of imposing the charge on those by whom in equity it should be borne.

Cost of Medical Study.

Dr. Hadrich, secretary to the Leipziger Verband, estimates the cost of lectures for the five theoretical terms of study at M.875 (£44), and for the six clinical terms at M.1800 (£90). The expenses of living as a student for five and a half years, excluding clothes and with some assistance from scholarships, he puts at M.2805 (£140). Fees for the State examination (£17), books and instruments (£28), the cost of taking the M.D. degree, with printing of the dissertation (£30), bring the total cost of the study to M.6988 (£349). The expenses of starting practice are estimated at £250 to £500, including furniture, and a further £35–£60 has to be found for instruments. The cost of keep during the university vacations and of clothes are not included in the above figure. The expenses may be lessened if the lecture fees are deferred, and if advantage is taken of certain privileges of students, but this is possible only for students who prove especially able. After having settled, the medical man must wait some years before being admitted to club practice which for the average doctor is the basis of his livelihood. All things considered, there is little hope of his paying at an early date the debts he may have incurred for medical education.

Professional Secrecy.

Some time ago, in the course of a demonstration, a university teacher mentioned the name of the man whose body was being dissected. This man, who had died in prison, had been found guilty in a financial scandal which had caused a great sensation, and the professor, in commenting on his character and behaviour, produced evidence that he had suffered from syphilis. The newspapers having reported the incident, the Minister of Public Instruction, who is responsible for university affairs, has written a letter to the professor blaming him for having acted against the rules of professional secrecy which are valid not only for practitioners but also for pathologists. Disciplinary measures have not been taken because the professor is in any case about to vacate his chair on account of age.

The Guttadiaphot.

At the Berlin Medical Society Prof. Victor Schilling, the well-known author of several works on diseases of the blood, has been demonstrating an apparatus for hæmatological research, devised by two medical men of Hanover, Dr. Meyer and Dr. Berast, and tested by himself. The principle of the apparatus, which is called the guttadiaphot, is that a drop of blood absorbed by blotting paper impregnated with certain chemicals assumes various appearances in various diseases; thus the appearance differs in syphilis, septicæmia, and tuberculosis. The edge of the drop shows in some diseases a corona, whilst in others there is none; also the staining of the centre is characteristic in different pathological conditions. In syphilis the results of the guttadiaphot test accorded with those of the Wassermann reaction.

Forthcoming Conferences.

A meeting of the Society for the Study of Diseases of Digestion and Metabolism will take place in Amsterdam from Sept. 12th to 14th. The physiology and pathology of hunger, the relation between the digestive tract and blood diseases, and the avoidance of errors in diagnosis and treatment of diseases of digestion will be the principal subjects of discussion. An exhibition of pharmaceutical preparations is being arranged. Further particulars may be obtained from the general secretary, Prof. von den Velden, Bamberger Str. 49, Berlin W. 30.

The eighth meeting of the German Pharmacological Society will be held from Sept. 12th to 15th in Hamburg, in the rooms of the Pharmacological Institute. On Sept. 13th, in the morning, a symposium on the functions of the heart and blood-vessels will be given, in honour of William Harvey. The physiological and pharmacological aspects will be discussed by Dr. Liljestrand, of Stockholm, and Dr. Jarisch, of Innsbruck; the pathology of cardiac function, by Dr. H. Straub, of Göttingen; and the pathology of the vascular system, by Dr. Eppinger, of Freiburg. The afternoon will be devoted to addresses by Dr. G. V. Anrep (Cambridge) and Dr. G. Mansfeld (Pécs) respectively, on new studies in the physiology and pharmacology of the coronary arteries, and on the problem of dilatation of the heart. On Sept. 14th industrial poisoning will be discussed, from the toxicological standpoint, by Dr. Flury, of Wurzburg, and from the hygienic standpoint by Dr. Zangger, of Zurich. On Sept. 15th Prof. G. Barger, of Edinburgh, will give an address on the active principles of ergot. A detailed programme will be issued in July. Those who wish to give communications are asked to apply to the President, Prof. G. P. Pick, 13A, Währingerstrasse Vienna IX, before the end of June.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Public Health in Hungary.

IN the course of a recent address Dr. George Gortvay, Secretary of State, advocated the establishment of a special commission to study the diet of the people, and to improve it by promoting the consumption of vegetable proteins, fruit, and milk, in place of the almost exclusive consumption of carbohydrates and fat. The Magyar peasant, when at work, he said, eats bacon and bread four times a day.

Referring to the vital statistics of the Hungarian people, Dr. Gortvay stated that the increase in population in some counties—mainly in those where most of the population consisted of small industrial workers and agricultural labourers—was gratifying, but that in others the birth-rate lagged behind the death-rate. To combat the "one-child" system, he suggested that the State should colonise the "one-child" districts with "many children" families, for he considered that the psychologically and bodily degenerate inhabitants of the "one-child" districts were already past saving. Similarly, in the fight against alcoholism, it was not nearly so important to deal with 200 or 300 unfortunate chronic drunkards as to inculcate a distaste for alcoholism in the younger generation as a whole. In the campaign against artificial abortion, he did not seek the remedy in the introduction of severer penalties, but in the compulsory notification of all cases of pregnancy. Physicians and midwives should be obliged to report every case of pregnancy to the medical officer of the town and it should be his duty to see that the pregnant woman obtained moral and financial support. Speaking of the infant mortality in the low-lying districts, Dr. Gortvay said that it was a real catastrophe that in these areas the death-rate among new-born children should be from 30 to 40 per cent. Cancer had shown an increase of 25 per cent. since 1922, and twice as many people died as a result of rheumatic diseases as from infectious diseases. In 1925 there were 4000 cases of enteric fever—a wholly preventable disease—1086 of which were fatal.

The increase in the death- and sickness-rates meant a very large addition to the national expenditure, and Dr. Gortvay exhorted the medical societies of Hungary to deal more vigorously with the problem of prophylaxis, in which they must secure the coöperation of the nation and the community.

Medical Periodical in Four Languages.

A new medical journal, the *Monatsschrift Ungarischer Mediziner*, has been launched in Budapest under the able editorship of Dr. I. E. László. The object of this periodical is to make the progress of the Hungarian medical and scientific world known to foreign countries. The journal appears in German, English, French, and Italian.

International Congress on Industrial Hygiene.

Since 1913 no international medical congress has been held in Budapest. It is not surprising, therefore, that the preparatory committee of the Congress on Industrial Hygiene, to be held from Sept. 28th onwards, should be doing everything in its power to draw up a very interesting programme. Prof. Tibor Györi, president of the organising committee, has asked all the native representatives of medical and sanitary science, and a number of distinguished foreign pioneers of industrial hygiene, to read papers and give addresses; up to now more than 20 foreign experts have declared their willingness to take part, while 45 will give lectures. Nicholas Horthy, Governor of Hungary, has been asked to be patron of the Congress, and the Minister of Public Welfare has decided to arrange, in conjunction with the Congress, an exhibition of appliances for the protection of workmen, and of instruments used in industrial hygiene. Information may be had from the office of the Congress,[1] Népegészségügyi Muzeum, Eötvös-street 3, Budapest, VI.

Medical Journal Abused by an Advertiser.

Not long ago some astute pharmaceutical manufacturers tried to bring grist to their mill by sending out circular letters containing articles, or extracts from articles, from respectable medical journals, the suggestion being that the use of these paragraphs would be approved by the papers in question. Last winter the *Orvosi Hetilap*, the leading Hungarian medical paper, sued a pharmacist for an offence of this kind. The court sentenced the offender to a very heavy fine, and compelled him to send the sentence, which occupied about four printed pages, to all medical men to whom the objectionable advertisement had been forwarded, and to publish it in full in all Hungarian medical journals. In spite of this another breach of the same kind was discovered last week. A manufacturing chemist of Ujpest sent a circular advertisement, in the form of a small booklet, to doctors and pharmacists under the title "Scientific Publications of the *Orvosi Hetilap*." The booklet contained extracts from, and summaries of, articles on different diseases, published in the *Orvosi Hetilap* in 1926, emphasising the efficacy, in general, of some ordinary well-known and old-established drugs, as for instance, iodine, guaiacol, and salicylate of soda. The firm exploited these by recommending its specialty, a patent medicine, which contained, among other things, iodine and guaiacol, and the advertisement was so framed as to make it appear that the articles in the journal bore witness to the efficacy of this patent medicine. The editors of the paper have taken legal proceedings against the offenders. It is to be hoped that in this case the sentence of the court will be even severer than that inflicted on the former occasion.

A Tribute to Harvey.

A recent number of *Orvoskepzes*, a bi-monthly journal, issued by the Central Committee for Post-graduate Medical Teaching, is dedicated to the memory of William Harvey. The number contains several illustrations, and includes a paper, in English, by Prof. Emile Grosz, president of the Central Committee for Post-graduate Medical Teaching, who gives a short sketch of Harvey's life and an appreciation of his work, ending with the statement that he played the same rôle in medicine as was played in astronomy by Copernicus, Newton, and Kepler.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Debate on Public Health Work in the Dail.

ON the vote for the Department of Local Government and Public Health recently in the Dail, several deputies took occasion to discuss matters affecting public health. Mr. S. T. O'Kelly (F.F.) drew attention to the absence of any references to the recommendations in the report of the Commission on the Poor Laws. The Government had not given the lead it should in health work and was to blame for the backward condition of child welfare work. The sanitation of small towns was not receiving proper attention. The housing policy of the last five years had left Dublin with an increased slum population. Sir James Craig (Ind.) asked for information as to the number of counties that had made provision for the appointment of medical officers of health, and as to the progress of the scheme of medical inspection of school-children. Poor people had great trouble in having their vision tested. Dr. O'Dowd (F.F.) suggested that sanitation should be tackled in the same way as the road question had been tackled. He thought that county homes should be turned into proper hospitals, and that in every county hospital there should be a surgeon who was able to undertake all classes of general surgical work. Mr. Corish (Lab.) said that the officials of the Department had a good progressive outlook, and if there were enough money available many of the things complained of would doubtless be remedied. They had arrived at a stage, however, when there should be Government intervention to get even a few of the towns and villages into a proper sanitary condition. Several deputies joined in the demand for increased housing and improved sanitation.

Memorial to Dr. McKisack.

A meeting of subscribers to the memorial to the late Dr. H. L. McKisack was held at Belfast on June 1st, with Mr. T. S. Kirk in the chair. Mr. Edwin D. Hill and Mr. Stanley Ferguson, the hon. treasurers, reported that the total subscriptions received to date amounted to the sum of £555 9s. It was unanimously agreed: (1) That a bronze memorial tablet in memory of the late Dr. McKisack be placed in the hospital, this to be paid for out of capital. (2) That the rest of the capital be made the nucleus of a McKisack Research Fund, the income of which to be devoted to the study of disease, injuries, and deformities in all their aspects, including the study of the results of treatment. (3) That the fund be kept open for future donations, with no limitation as to the amounts. (4) That the fund be in the keeping of, and administered by, the Board of Management of the Royal Victoria Hospital, Belfast, on the recommendation of the visiting medical staff of the hospital. It was further decided that the details of carrying out the terms of these resolutions should be left in the hands of the following committee: Mr. T. S. Kirk, Mr. Hill, Mr. Ferguson, Dr. Robert Marshall, and Dr. Andrew Trimble.

KING EDWARD VII. HOSPITAL, WINDSOR.—At the annual meeting it was stated that in addition to replacing the two wards recently burned, further extensions are necessary. More beds for women and children are needed as well as better accommodation for nurses and more room for out-patients. In one day 43 accident cases were taken to the hospital, and a large proportion of the injured persons had to be detained as in-patients.

MEDICINE AND THE LAW.

Criticisms of the Coroners Acts.

Two criticisms have recently been directed against the existing law of coroners' inquests. One was a complaint by the West London coroner of the protracted adjournments of the inquisition upon the death of Mr. A. C. B. Webb, who was shot at his flat in Bayswater in February last. Mr. H. R. Oswald pointed out that, owing to the length of the parallel proceedings in the criminal courts, the inquest had been three times adjourned. Frederick Stewart having been condemned to death for the murder of Mr. Webb, and his appeal against conviction having been dismissed on May 21st by the Court of Criminal Appeal, the West London coroner has now formally recorded a verdict of "murder" against him. Mr. Oswald's point is that, if the amending Act of 1926 had not been passed, the coroner's jury could have made up its mind upon the case at its second sitting; the 1926 amendment of the law was supposed to save public expense and to prevent the simultaneous inquiry by two courts; in this particular instance, however, the expense has actually been increased, and the diminution of the coroner's jurisdiction has proved no economy at all. Section 20 Subsection (6) of the 1926 Act makes it clear that the coroner's adjournment in such a case should be to such a date as will cover the final disposal of a possible application to the Court of Criminal Appeal. The terms of the section have rightly been regarded as deprecating an indefinite adjournment *sine die*; but, if the concurrent criminal jurisdiction is drawn out for so long as three months, it may prove the most convenient course to adjourn the inquest without naming a date.

While many regret that the coroner's inquest should have been deprived of an important part of its jurisdiction in this manner in 1926, the other recent criticism comes from quite another side, and suggests that the coroner's jury should not be pressed to return a verdict of guilty against any named person. Mr. H. A. Hollond, of Cambridge University, has written to the *Times* to deprecate the procedure in the inquest upon the body of Harry Pace (reported in the *Times* of May 23rd). The jury first reported its opinion that the case called for further consideration. The coroner was then obliged to remind them that, if they wished proceedings to be taken, they must name the person or persons. The jury thereupon revised its verdict and returned the finding that Harry Pace met his death by arsenical poisoning administered by Beatrice Annie Pace. This, says Mr. Hollond, is a breach of the good English rule that an accused person is treated as innocent until proved guilty. The relevant statutory provision is Section 4 Subsection (3) of the Coroners' Act of 1887, which enacts that the jury, after hearing the evidence, must give their verdict, and must set forth (so far as the particulars are proved) various matters, including, in cases of murder or manslaughter, the persons (if any) whom they find to have been guilty. The statute here does little more than repeat the ancient duties of the jury to be traced in the famous enactment *De Officio Coronatoris*, and unless the coroner's inquest is to be deprived yet further of its powers as a part of the machinery for setting the law in motion against a possible murderer, there seems no reason why the substance of the law should be changed. Mr. Hollond complains that the fact of the jury's finding against Mrs. Pace will stand recorded in all the newspapers of the country, though she has not been tried and though she is entitled at this stage to be treated as innocent. He would presumably be satisfied if the inquest in such cases merely committed a person for trial, instead of recording an actual verdict of guilty. The primary object of an inquest is to determine the cause of death, but any change in the law would cut very deep into the roots of the past; the chances of such a change being made depend upon the extent to which public opinion is aroused.

Forged Certificate of Chemist's Qualification.

Ralph Valentine Edwards was sentenced last week to six months' imprisonment with hard labour for attempting to obtain a week's wages as superintendent chemist by false pretences. He appears to have represented to an Albany-street chemist that he was a qualified chemist, and to have produced in support of his statement (though he denied having done so) a tracing of a certificate of qualification by the Pharmaceutical Society, so skilfully done that it was thought to be a photograph of an original certificate. A detective-sergeant said that on April 29th Edwards was bound over at the London sessions for two years on a charge of possessing cocaine and morphine. He had then obtained a situation by means of a forged certificate. Morphine and cocaine were found in his possession and the police described him as a drug addict. Mr. Hay Halkett, in passing sentence at Marylebone police-court, remarked that the accused might have poisoned the whole of Albany-street.

Milk Frauds and Habitual Offenders.

Under the heading "Dairyman Imprisoned" the suggestion was made, on p. 1140 of THE LANCET, that habitual offenders might with advantage be debarred from taking any further part in the sale of food. In a letter printed on p. 1201, Prof. H. Kerr, of Newcastle-upon-Tyne, courteously points out that Section 2 of the Milk and Dairies (Amendment) Act of 1922 enables local authorities to remove from the register of persons registered as retail purveyors of milk any one who is convicted of a milk offence. This power of removal from the register is of course a most material remedy and deserves widespread publicity. It is given by Parliament in almost every case where compulsory registration or licensing is required, whether for milk-selling, motoring, money-lending, or other matters. But what was suggested in this column was something wider. The habitual offender, if removed from the register of milk retailers, may take up the sale of meat, fruit, or vegetables, or other kinds of food, or he may continue in some subordinate position in the milk trade. It is not enough to strike a man off the register; his further employment —as the solicitors' profession has discovered—may be dangerous. A man who will persistently swindle the public over the sale of milk is not to be trusted in the sale of any kind of food whatever. Our ancestors in robuster times might have held such a man up to public contempt by putting him in the stocks; for many offences the punishment of branding remained upon the statute book until almost modern times, so that honest citizens might know the man with whom they had to deal. Even to-day it is possible—e.g., under Section 47 of the Public Health (London Act) of 1891—to order the posting-up on his premises of particulars of the conviction of a man who has twice in the year been convicted of selling unsound food. If offenders have no conscience towards the public in matters of health, a certain vindictiveness of punishment may be deemed justifiable.

CHILDREN'S HOSPITAL, BRIGHTON.—During their visit to Brighton on May 30th the Duke and Duchess of York opened a new wing at the Royal Alexandra Hospital for Sick Children in Dyke-road. The new wing provides accommodation which has been badly needed. On the ground floor is a room for ultra-violet ray treatment and a receiving room for new cases. On the floor above is an operating theatre, fitted with the most modern light appliances, and, adjoining it, a dark theatre equipped for the examination of defective eyes and ears. On the same floor is an anæsthetic room, and at the top of the building are flats for the accommodation of resident medical men. A large lecture hall has also been built over the out-patients department. Their Royal Highnesses, on the same day, also visited the Prince Albert Convalescent Home at Worthing.

GENERAL MEDICAL COUNCIL.

SUMMER SESSION, 1928.

PENAL CASES.

MONDAY, MAY 28TH.

Improper Contributions in the Lay Press.

The Case of Reginald Francis Edmund Austin, registered as of 41, Wimpole-street, W. 1, M.R.C.S. Eng. 1891, L.R.C.P. Lond. 1891, who appeared before the Council on the following charge:—

"That, being a registered medical practitioner, you have sought to attract to yourself patients and to promote your own professional advantage by means of an article upon appendicitis written by you and published in the number for December, 1927, of the magazine *Health and Efficiency*, in which you extolled your own methods and depreciated those of other practitioners."

Mr. O. Hempson, in opening the case for the complainants, the Medical Defence Union, explained that his society had made this report because it deprecated the increasing tendency of practitioners to communicate articles on medical matters to the lay press. Before reading the offending article he commented on general aspects of the case. A man must, to a certain extent, be judged by his associates, and a glance at the pages of this periodical showed a succession of advertisements commending so-called "cures." The tendency throughout the paper was to attract patients to the exponents of these "guaranteed cures," and away from the qualified medical profession. A man who published an article in any journal ought first to acquaint himself with the nature of that journal, and Dr. Austin must have known what this one was like, for he had been asked to write a series of articles for it, and had been introduced to its readers in the April number in the following words:—

"It gives us the greatest pleasure to announce an important series of articles on the Nature Cure from the accomplished pen of Major Reginald F. E. Austin. . . . The nature cure is come, just as surely as the drug and serum superstition is bound to go, and among the enlightened band of medical men who are advocates of a saner medical treatment, none holds a more distinguished place than Major Austin."

Mr. Hempson did not suggest that Dr. Austin was in any way responsible for this eulogy, but he must have had his attention drawn to it, and it was his duty to keep a closer watch on the paper than he had.

The article (copies of which were circulated to members of the Council) was headed "Nature Cure Explained. The Truth about Appendix Operations. An Insane Medical Craze Exposed. By Major Reginald F. E. Austin, M.R.C.S., L.R.C.P." Inset was a portrait of the late Miss Florence Mills (the leader of the famous Blackbird company of negro actors) with the caption "Yet another victim of operation for appendicitis." The Union accepted the respondent's statement that these embellishments, except for "Nature Cure Explained" and his name, were not Dr. Austin's work, but this fact afforded small justification. The editor reserved the right to make minor alterations, and had presumably already exercised it in the earlier articles. Surely respondent should insist on seeing his work in its final form before publication.

Mr. Hempson read the article, commenting especially on certain phrases. The opening paragraphs were written largely in the first person: "Frequently I am asked the question . . . invariably my answer is . . . I would not advise . . . In no case has life been lost by my patients, even in gangrenous and pus cases"; all of which was in the traditional manner of the "guaranteed cure." Dr. Austin had quoted, in denouncing the operative treatment of appendicitis, the "chestnut" about the surgeon who operated on a patient who had a 100 guineas; nothing more insulting to his profession could be imagined than the introduction of that anecdote into an article of this kind. Another offensive phrase was "The (germ) theory is popular because it absolves us from all responsibility for our troubles; hence most writers on appendicitis play to the gallery, but ingenuously give themselves and the germ theory away." It constituted a strong disparagement of the profession as a whole. Mr. Hempson was not discussing the merits of respondent's methods, but his manner of presenting his criticism, and his unjustifiable suggestion that the advocates of other methods were dishonest. Another passage to which the Medical Defence Union objected especially was, "All cases which rupture into the abdominal cavity are caused by the doctor himself in his efforts to make a diagnosis." The article concluded with the description of a case successfully treated by the writer. On another page of the issue there was an editorial comment on the article. The editor had accepted respondent's disparagement of his professional colleagues, and this comment, Mr. Hempson submitted, was the direct outcome of the article. It was headed "Do Have a Taste of Our Nice Cold Steel," and attacked surgeons in general as "apostles of the knife," who conducted energetic and insidious propaganda in the daily press to enrich themselves and gratify a mania for operations akin to the lust of the vivisector for experimenting on living animals. Nothing could more clearly point out how pernicious were articles like Dr. Austin's. Mr. Hempson then read extracts from the advertisement pages to illustrate the extent to which they were used by unqualified medical practitioners.

Respondent, in evidence, said that he had been practising "nature cure" methods for 20 years. He had from time to time contributed articles and letters to the medical press of India and this country, mostly on "nature cure" methods. The present series, however, with the exception of a few letters, was the first work he had ever contributed to the lay press. His remarks about treatment were the absolutely sincere expression of his own views; he was sorry if he had given the impression that he wished to attack professional colleagues. In answer to the Legal Assessor, he said his original heading had been "The Appendicectomy Insanity"; he had used the word insanity in a moderate sense, as he would in criticising any current craze. He had interviewed the editor and protested at the alterations and the portrait of Miss Mills. None of the previous articles in the series had been illustrated, and he had had no reason to suppose that the editor would insert a picture and a caption of this kind. No proofs had been sent him, and he had known nothing about the editorial until the magazine had appeared. He had had no intention of commending his own personal treatment, but only that carried out by the body of "nature cure" practitioners, of which he was one. None of his former articles mentioned his patients. Cross-examined, he stated he had intended to disparage not men, but methods; he had thought the "chestnut" about the surgeon was a very innocent one, and respondent had seen it in medical journals. He believed that all his professional brethren who did the appendix operation honestly believed it to be necessary. He had seen many cases of ruptured appendicular abscess, all of which, in his opinion, had been caused by palpation; this was the fault of the method. He admitted having read through the advertisements in the paper, which he had taken in. He had not approved of the editorial, but had been powerless to stop it. He had interviewed the editor before the British Medical Association had written to him, as some lay friends had represented to him that the article was unfortunately expressed. Dr. Austin's counsel read a statutory declaration from the editor of *Health and Efficiency*, in which it was stated that the articles would not have been published without Dr. Austin's name at the head. No proofs had been submitted. The editor reserved the right to edit articles without

asking their author's opinion. The photograph and caption had been inserted unknown to respondent, who had remonstrated with the editor after the publication of this issue.

Respondent's counsel, in his address, expressed his client's great regret that he should have, quite unintentionally, expressed himself in a way that went beyond the canons of good taste and professional practice. Dr. Austin, as an earnest of his sincerity, wished to give the Council his solemn promise that he would contribute no further articles to the lay press.

Mr. Hempson submitted that his society were content to lay the facts before the Council, and did not wish to press the charge unduly. The Council found that the facts amounted to infamous conduct in a professional respect, but postponed judgment for 12 months, subject to the usual conditions.

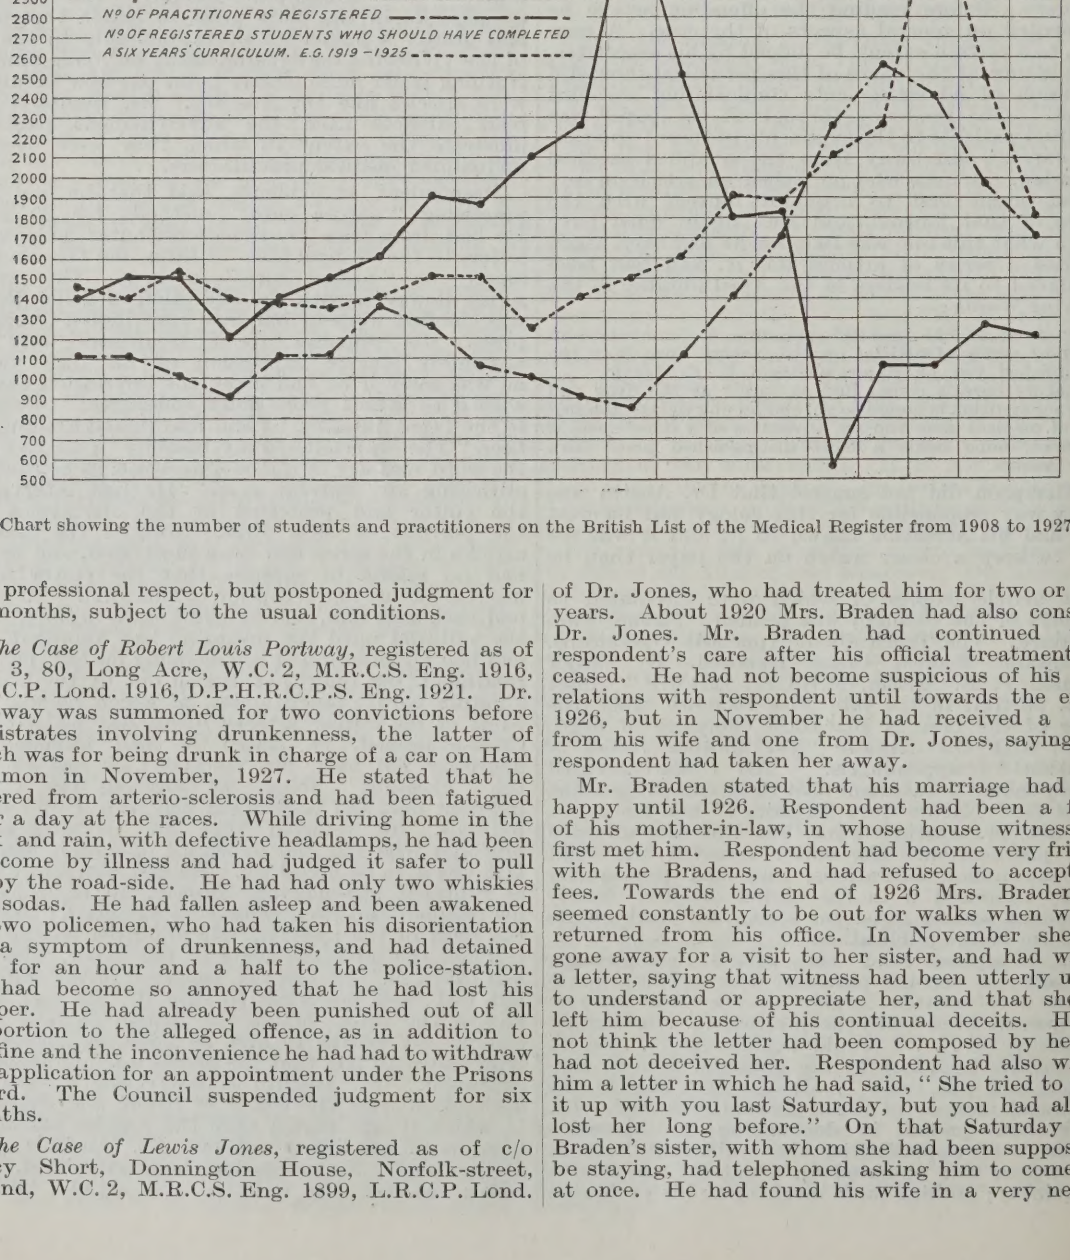

Chart showing the number of students and practitioners on the British List of the Medical Register from 1908 to 1927.

The Case of Robert Louis Portway, registered as of Flat 3, 80, Long Acre, W.C. 2, M.R.C.S. Eng. 1916, L.R.C.P. Lond. 1916, D.P.H.R.C.P.S. Eng. 1921. Dr. Portway was summoned for two convictions before magistrates involving drunkenness, the latter of which was for being drunk in charge of a car on Ham Common in November, 1927. He stated that he suffered from arterio-sclerosis and had been fatigued after a day at the races. While driving home in the dark and rain, with defective headlamps, he had been overcome by illness and had judged it safer to pull up by the road-side. He had had only two whiskies and sodas. He had fallen asleep and been awakened by two policemen, who had taken his disorientation for a symptom of drunkenness, and had detained him for an hour and a half to the police-station. He had become so annoyed that he had lost his temper. He had already been punished out of all proportion to the alleged offence, as in addition to the fine and the inconvenience he had had to withdraw his application for an appointment under the Prisons Board. The Council suspended judgment for six months.

The Case of Lewis Jones, registered as of c/o Percy Short, Donnington House, Norfolk-street, Strand, W.C. 2, M.R.C.S. Eng. 1899, L.R.C.P. Lond. 1899, who appeared before the Council on the following charge :—

"That, being a registered medical practitioner, you abused your position by committing adultery with Alice Mary Braden, a married woman, with whom and whose husband you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated June 2nd, 1927, and made absolute on Dec. 12th, 1927, in the case of Braden *v.* Braden and Jones, in which you were the co-respondent. And that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

The facts, as stated by the Council's solicitor, were that Mr. Braden was married in 1918, and that in 1919 he had been discharged from the Army as unfit. The medical board had placed him under the care of Dr. Jones, who had treated him for two or three years. About 1920 Mrs. Braden had also consulted Dr. Jones. Mr. Braden had continued under respondent's care after his official treatment had ceased. He had not become suspicious of his wife's relations with respondent until towards the end of 1926, but in November he had received a letter from his wife and one from Dr. Jones, saying that respondent had taken her away.

Mr. Braden stated that his marriage had been happy until 1926. Respondent had been a friend of his mother-in-law, in whose house witness had first met him. Respondent had become very friendly with the Bradens, and had refused to accept any fees. Towards the end of 1926 Mrs. Braden had seemed constantly to be out for walks when witness returned from his office. In November she had gone away for a visit to her sister, and had written a letter, saying that witness had been utterly unable to understand or appreciate her, and that she had left him because of his continual deceits. He did not think the letter had been composed by her; he had not deceived her. Respondent had also written him a letter in which he had said, "She tried to patch it up with you last Saturday, but you had already lost her long before." On that Saturday Mrs. Braden's sister, with whom she had been supposed to be staying, had telephoned asking him to come over at once. He had found his wife in a very nervous

condition, and after an interview of two or three hours she had confessed to misconduct with Dr. Jones. He had forgiven her, but said he could not take her back home immediately. She had, however, come to the train by which he was leaving, and he had taken her back. She had told his mother everything, and a very distressing talk had followed, at the end of which she had left to go to her mother's. From there she had gone to live with Dr. Jones. Witness produced some medicine bottles inscribed to himself and his wife, which he said had been sent by Dr. Jones shortly before his wife left him. He had been asked by the Council to give evidence, and had no vindictive feeling towards respondent. He denied having made his wife unhappy. Cross-examined, he admitted having met Dr. Jones socially before he came under his treatment. He and his wife had only quarrelled once about other women, and then only for a short time. He had once asked her mother to take her back for a few months, believing that after as much as nine years of married life it was good for a couple to separate for a little. His wife had occasionally visited a Dr. Jessie Maxwell, but Dr. Jones was primarily her medical attendant. She had only gone to Dr. Maxwell after she had become very friendly with Dr. Jones. Dr. Jones had treated her the week before she had joined him. He admitted he had struck his wife in the face, but that had been in the course of the quarrel after he had taken her back and forgiven her. In answer to the Legal Assessor, witness stated that up to 1926 Dr. Jones had treated his wife more or less regularly two or three times a year. Dr. Jones had been paid by the Ministry of Pensions for witness's treatment, but had never sent in any accounts for his wife or his father.

Respondent, in evidence, said he had never attended Mrs. Braden professionally. The most he had done was to give her an aspirin once or twice. He had never attended Mr. Braden except under the Ministry of Pension's scheme. He had called frequently at the house, but only socially; he had taken Mrs. Braden out motoring every Saturday. The bottles marked with Mrs. Braden's name had been taken back to Mr. Braden's house by Mrs. Braden from Richmond, where she was staying with witness. She had had a cold, and had gone back to her husband's house once or twice. He denied having broken up Mr. Braden's home. Even in 1925 Mr. Braden had told him he was in love with another woman.

Mrs. Braden corroborated Dr. Jones's evidence; the bottles had been labelled with her name to allay suspicion. She had been treated by Dr. Maxwell for 14 weeks.

The Council decided that the facts had not been proved to their satisfaction, and dismissed the case.

The Case of Samuel Nagley, of 169, High-street, Homerton, E. 9, was postponed until the Council's next session, owing to the ill-health of the complainant.

FRIDAY, MAY 25TH: COMMITTEES.

Dr. D. J. Coffey, President of the Irish Free State Medical Council, was elected a member of the Penal Cases Committee. By an agreement between this country and the Free State, it is laid down that all penal cases referring to Irish practitioners on the English register shall be reported to the Irish Council, and that the Irish Council shall report all its penal cases to the General Council, so that double prosecution may be avoided. The presence of Dr. Coffey on this committee will ensure an adequate liaison between the disciplinary proceedings of the two Councils.

Finance.—The receipts from registration fees have decreased in England by £655, in Scotland by £302, and in Ireland by £500. The report includes a graph (given herewith) of the numbers of students and practitioners registered in each year since 1900; from this it appears that the falling-off due to the 1923 Regulations should continue for another two or three years.

Public Health.—As five years have now elapsed since the new rules came into force, the Council will now begin to inspect the examinations held by the licensing bodies for the Diploma of Public Health.

The London Conjoint Board wrote to the Council in November, 1927, to inquire whether the 120 hours' parasitology included in the five months' course at the London School of Hygiene could be accepted as reducing in any way the 180 hours of bacteriology and parasitology required for admission to Part I. of the D.P.H. The Committee, in a memorandum answering the Board's question, pointed out that the two courses had different aims in view, and that the dissimilarity between them would grow as time went on. Moreover, if partial exemptions were to be granted readily, the length of the curriculum would be gradually reduced; this would be a retrograde step. The Committee therefore, while willing to consider any case on its merits, found themselves unable to grant any general exemption.

Pharmacopœia.—The sale of the British Pharmacopœia continues to increase, the total number of copies sold since May, 1927, being 2476. The Chairman of the Committee, Sir Donald MacAlister, referred at length to the work of the Subcommittee of the Committee of Civil Research (on the findings of which we commented in a recent issue[1]). The Council accepted the Committee's recommendations, thanking the Lord President for the report and approving the changes recommended in its conclusions, and authorised the Committee to take on the Council's behalf all necessary steps to carry them into effect.

The Council acceded to the request of *Harold Dearden*, M.R.C.S. Eng. 1911, L.R.C.P. Lond. 1911, to have his name removed from the Register on the grounds that he had ceased to practise.

[1] THE LANCET, May 26th, p. 1078.

ROYAL FREE HOSPITAL. — The one-hundredth annual report records that the average total weekly cost of each in-patient has fallen from £4 6*s*. 5*d*. to £4 2*s*. 0½*d*.; at 1*s*. 9⅝*d*. the cost of each out-patient attendance shows a fall of a fraction over a penny. These reductions have been achieved notwithstanding a general improvement in the dietary. The hospital is deriving an income of £4000 a year under the Inland Revenue arrangement which enables a subscriber, on certain conditions, to obtain a reduction of income- or super-tax. A reference to recent donations to the hospital will be found on p. 1188.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, June 11th, at 10 A.M., at the Royal Northern Hospital, Mr. Lane-Roberts will give a clinical demonstration in gynæcology, and on the same date, at 3 P.M., Mr. MacCallan will demonstrate at the Royal Eye Hospital. On Tuesday, June 12th, at 2 P.M., Dr. Anthony Feiling will hold a clinical demonstration at the Hospital for Epilepsy and Paralysis, Maida Vale, W. These demonstrations are open to the medical profession without fee. From June 18th, for a fortnight, special courses will be given at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, London, E., and at the Chelsea Hospital for Women. A general practitioners' course will be given at the London Temperance Hospital from June 18th to June 30th, from 4.30 to 6 P.M., and from June 25th to July 21st, at 5 P.M., at the West End Hospital for Nervous Diseases, a course will be held daily consisting of clinical demonstrations on selected cases. The Fellowship also provides a general course of instruction throughout the year which includes attendance at the clinics of the associated hospitals. Comprehensive tickets are issued and arrangements are made for those unable to do whole-time work. Copies of syllabuses and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship of Medicine at 1, Wimpole-street, London, W. 1.

MULTIPLE MALIGNANT TUMOURS.

To the Editor of THE LANCET.

SIR,—In THE LANCET for May 5th (p. 917) there is a leading article calling attention to the rarity of multiple malignant growths. I have always been of the opinion that multiple cancers are not so rare as is generally stated. I have therefore looked up my recent cases and find that in 310 successive autopsies on cancer patients at the Christie Hospital there occurred 14 undoubted cases of multiple primary malignant growths—i.e., 4·5 per cent., of which the site was as follows:—

1. Male, aged 55. (1) "Large round-celled sarcoma" of testis; (2) squamous carcinoma of peritoneum with secondaries in iliac glands.
2. Male, aged 67. (1) Squamous carcinoma of tongue; (2) columnar carcinoma of gall-bladder.
3. Male, aged 41. Carcino-sarcoma of pharynx: (1) squamous carcinoma arising in an ulcerating (2) spindle-celled sarcoma of the pharynx. Sarcomatous metastases in glands, thyroid, lungs.
4. Male, aged 53. (1) lymphosarcoma of the fourth lumbar vertebra with numerous metastases in glands, lungs, heart, pancreas; (2) one of the metastases in the lungs showed a combined tumour of lymphosarcoma and squamous carcinoma.
5. Male, aged 54. (1) Squamous carcinoma of the bladder; (2) spheroidal carcinoma of the liver.
6. Female, aged 46. (1) Columnar carcinoma of the rectum with metastases in abdominal and cervical glands, liver, ovary, thoracic duct; (2) columnar carcinoma of duodenum, apparently distinct from (1).
7. Female, aged 59. (1) Lymphosarcoma of left kidney and adrenal; (2) spheroidal carcinoma of pancreas with metastases in glands, ovary, thyroid, skull, brain, liver, both kidneys.
8. Male, aged 35. (1) Columnar carcinoma of rectum; (2) spheroidal carcinoma of cystic duct with metastases in glands, liver, spleen, kidney.
9. Male, aged 32. (1) Melanotic tumour of leg with secondaries in groin, abdominal wall, chest wall; in iliac, pelvic, aortic, gastric, and mesenteric glands; also in lungs, heart, both kidneys, brain; (2) large myxosarcoma (not pigmented) of left kidney, measuring $18 \times 7 \times 6$ in.
10. Female, aged 74. (1) Squamous carcinoma of skin of breast; (2) spheroidal carcinoma of the same breast with metastases in stomach, vertebræ, and spinal dura mater.
11. Female, aged 45. (1) Spheroidal carcinoma of breast with metastases in lungs; (2) spindle-celled sarcoma of same breast.
12. Female, aged 52. (1) Squamous carcinoma of tongue keratinising; (2) spheroidal carcinoma of œsophagus with secondaries in mediastinal glands.
13. Male, aged 56. (1) Squamous carcinoma of tongue not keratinising; (2) spheroidal carcinoma of œsophagus with secondaries in liver.
14. Female, aged 41. (1) A mixed columnar carcinoma and spindle-celled sarcoma in the pelvis recurrent from a columnar carcinoma of the ovary which had been removed 18 months previously, with carcinomatous secondaries in iliac, inguinal, and some abdominal glands; (2) spheroidal carcinoma of both breasts with secondaries in axillæ and some abdominal glands.

I have excluded from this list all cases which are reasonably open to doubt, such as one case in which there were two, apparently independent, squamous carcinomata of the œsophagus; five cases of spheroidal carcinoma of both breasts (simultaneous or successive); also a case of multiple spindle-celled sarcoma of both kidneys, and one or two others. During the period covered by these autopsies I have also met with a case (but not at the Christie Hospital) which resembles closely Case 4 in the list. It was a case of lymphosarcoma of the abdominal glands with numerous metastases in the bladder and elsewhere. One of the metastases in the bladder had involved the mucous membrane and showed a combination of lymphosarcoma and squamous carcinoma. I have also met with two cases of carcino-sarcoma and one combined lymphosarcoma and squamous carcinoma of the uterus, but these, being operation specimens, are not included in the list.

The only case in the list which is possibly open to doubt is No. 6. In this there was an ordinary carcinoma of the rectum—partly mucoid—with tall columnar cells. The duodenal growth, which had led to perforation into the peritoneal cavity, was composed of much shorter cells and was almost entirely necrotic. It had quite a different appearance to that of the rectal growth and its numerous metastases. In Case No. 8 the carcinoma of the cystic duct had the structure of a pancreatic growth and may have originated from a heterotopic portion of pancreas in the portal fissure.

There can be little doubt that the frequency with which multiple primary growths are recognised depends to a great extent on the thoroughness with which tumours, apparently secondary, are submitted to microscopic examination. It appears to be usually, but not always, the case that in these cases of multiple primary malignancy one only of the primary growths gives rise to metastases.

I am, Sir, yours faithfully,

CHARLES POWELL WHITE.

Christie Hospital, Manchester, June 4th, 1928.

IS THERE MUCH TUBERCLE IN THE SERVICES?

To the Editor of THE LANCET.

SIR,—The above question is not infrequently asked, but is any answer possible? Very careful calculations must be made before any useful answer can be given. Apparently the only comparison possible will contrast the death-rates in the Services with those of males of similar ages in England and Wales. Statistics of the three Services have been published complete for the four years 1922–23–24–25, so these years were chosen, and their combined death-rates, for tubercle, respiratory, and "other," calculated for males, England and Wales, at each five-year period from 15 to 45. These rates were then applied to a population such as that in each of the Services, and it emerged that if deaths occurred in each service in the same proportion as in civil life, there would, per 10,000 men, be expected in the Army, the youngest in age, from respiratory tubercle, 12·4 deaths, from "other" tubercle, 1·8 every year; in the R.A.F., 12·5 deaths from respiratory tubercle, 1·7 from "other," and in the Navy, in age the oldest, the figures would be 12·8 and 1·6. The civil death-rate from respiratory tubercle increases with age, but that from "other" tubercle diminishes.

Against these figures are to be set those published for these same four years by the Army and the Air Force, and by the Navy for 1925, the first year in which it differentiates both kinds of tubercle. Then we have, per 10,000 men, for the Army, 1·45 and 0·37; for the Air Force, 0·7 and 0·66; for the Navy (one year), 3·4 and 0·6. These are far less than the death-rates expected at civil rates; indeed, if the deaths expected be taken as 100 in each case, the deaths that occurred, expressed as percentages, will be for the Army, 11 and 20; R.A.F., 5 and 38; for the Navy, 25 and 40. Hence it appears that men in the Services had in these years a smaller risk of dying of tubercle than if they had not joined, and particularly in respect of respiratory tubercle, the deaths from "other" tubercle not being equally reduced. In fact, whether because of careful selection or better conditions of life, lodging, food, exercise, or climate, fewer of the 300,000 men in the Services die in any year of tubercle than will die from it in a chance sample of the same number and age in civil life, 100 civil deaths paralleling 16·6 in the Services.

Invaliding, of course, is also to be considered. The invalids of last year were removed from the Service, their deaths, if any, do not fall into the Service statistics, but go to increase the civil death-rate. Doubtless most of them recover, but as no figures

on the point are available, we can only display the tale of invaliding without drawing conclusions. The wastage, then, from tuberculosis, the total of invalids and deaths, per 10,000 men per annum, from each class of case in 1922–25 was: Army, 12·45 and 1·97; R.A.F., 14·0 and 3·82; for the Navy (1925 only), 25·3 and 3·6. Taking the expected deaths again as 100, and expressing these last figures as percentages, we have: Army, 100 and 109; R.A.F., 113 and 224; Navy, 197 and 225. Here, again, we seem to be shown that the Service life protects less against tubercle "other" than against respiratory tubercle, rather contrary to expectation, but this examination only covers, at the best, four years. Still it may suggest to others some more fruitful investigation.

I am, Sir, yours faithfully,

W. E. HOME,
Fleet Surgeon.

ENCEPHALO-MYELITIS FOLLOWING VACCINATION.

To the Editor of THE LANCET.

SIR,—Before answering the criticisms of Prof. Turnbull and Prof. McIntosh, published in your issue of May 26th, I think it might be useful if I referred briefly to the general question of disseminated myelitis (or encephalo-myelitis) which has been recognised for over 50 years, and whose possible relationship to disseminated sclerosis was suspected as long ago as 1872 (Westphal). The number of histological investigations of the central nervous system in the former condition is not a very large one. These descriptions are very often marred by the fact that either only a portion of the central nervous system, usually the spinal cord, was investigated, or more often the histological methods employed were totally inadequate for the study of nervous tissues. Yet the principal features of this condition are not unknown. The case described and illustrated by J. Dreschfeld [1] in 1894 may be taken as quite typical of this condition, at any rate for the spinal cord. The characteristic perivascular demyelination, its symmetrical distribution on the two sides, the occurrence of patches of naked-eye softening (semi-liquefaction) in the cord and the consequent tract degeneration as the result of this destructive lesion, are all well illustrated. The demyelination in disseminated myelitis is always strictly perivascular and symmetrical in distribution. Although similar isolated perivascular lesions are found in acute cases of disseminated sclerosis, the large, progressive and usually asymmetrical patches of demyelination serve to distinguish it from disseminated myelitis. There is much reciprocal confusion in the literature in regard to these two conditions, and the labels attached to particular cases have varied widely. The occasional involvement of the optic nerves in either condition has served to increase this confusion, whilst the patches of true softening in the spinal cord in disseminated myelitis could only further complicate matters by leading to a diagnosis of "transverse myelitis." Some cases recorded would appear to be transitional forms between these two types.

The association of disseminated myelitis (or encephalo-myelitis) with acute infections has been well known almost ever since this condition was first recognised. Dreschfeld's own case was apparently not so associated with an acute infection, although he was perfectly aware of this association, as he refers to it in his article. In recent years cases of disseminated encephalomyelitis seem to have attained almost epidemic proportions. Of the acute infections with which it has been most commonly associated, vaccinia and measles head the list. The first (1912) histological recognition of this condition when associated with vaccinia we owe to Prof. Turnbull. A very good recent description of a case associated with measles is that of Wohlwill.[2] In going through the literature of this subject I have had to try and interpret in neuropathological terms the descriptions which are too often based on staining methods quite unsuited for nervous tissues. Yet many of these descriptions are extraordinarily accurate in spite of this disadvantage. It is without hesitation that I state that from the accounts to be found in the literature, disseminated (encephalo-) myelitis is a *pathological entity*, whatever its association with an acute infection may be. Clinically, there must be a wide range of variations according to the part of the central nervous system which is most severely attacked, &c. I have recently seen the spinal cord of a case associated with vaccination, where a patch 1 in. long of gross colliquative softening was present. In view of the wide problem presented by disseminated (encephalo-) myelitis as a whole, one might perhaps attach an undue degree of importance to certain matters of histological detail. *The type which is associated with vaccinia is histologically indistinguishable from the others.* It seems, therefore, that those of us who have been studying this condition have been rediscovering America. The most important new contribution to the histology of this condition is its association with vaccinia, an observation which we owe to Prof. Turnbull.

With reference to the letter of Prof. Turnbull and Prof. McIntosh, I should like to suggest that if any misunderstanding has arisen in regard to their description of the perivascular demyelination met with in disseminated (encephalo-) myelitis when associated with vaccination, it might possibly be ascribed to their use of the word "softening," which by itself is lacking of any precise histological meaning, for a lesion of the myelin sheath only. Yet I made it quite clear in a footnote in my paper that they did associate this "softening" with "loss of the myelin sheath." As they stressed the "softening" throughout their paper and only referred to the "loss of the myelin sheath" once, it seems to me fairly obvious that they did not stress the "demyelination." With regard to the two types of lesion which they described, I failed to confirm this observation of theirs, and made no reference to it in my paper. I only found "perivascular demyelination" as the characteristic lesion of this condition, as it is in all cases of disseminated (encephalo-) myelitis, whatever the latter's association may be with an acute infection. This lack of agreement might possibly be ascribed to the fact that Prof. Turnbull's and Prof. McIntosh's study is principally based on paraffin sections stained in the ordinary way, whilst I employed the methods specially devised for nervous tissues. I gather from their letter that in my desire to give them all the credit for the recognition of the areas of "demyelination" I have quoted their words a little loosely and have attributed to them more than they actually claim. I hope that the "many" who derived a wrong impression of the work of Prof. Turnbull and Prof. McIntosh as the result of reading my paper are sufficiently interested in this subject to read their article as well, and thereby banish the misconceptions for which Prof. Turnbull and Prof. McIntosh apparently hold me responsible.

I am, Sir, yours faithfully,

J. R. PERDRAU.

HABITUAL OFFENDERS AND THE SALE OF FOOD.

To the Editor of THE LANCET.

SIR,—On page 1140 of the current number (June 2nd, 1928) of THE LANCET the statement is made under "Dairyman Imprisoned":—

"It would be to the public advantage if the law allowed a court to make an order debarring such habitual offenders from taking any further part in the sale of food."

I would draw your attention to the fact that the law, The Milk and Dairies (Amendment) Act, 1922,

under which local authorities register both dairymen and dairies, by Section 2 definitely empowers local authorities to refuse registration where the public health is or is likely to be endangered by any act or default of any person registered or who seeks to be registered as a retail purveyor of milk, and in Subsection 2, the court before whom any person registered as a purveyor of milk is convicted of any offence under this Act, or any other enactment relating to milk and dairies, may, on the application of the local authority, in addition to any other penalty, order the removal from the register of the person so convicted by either absolutely or in respect of any specified premises for such period as the court may think fit.

I am, Sir, yours faithfully,

H. KERR,
Medical Officer of Health.

Health Department, City and County of Newcastle-upon-Tyne, June 1st, 1928.

*** This letter is the subject of comment under the heading "Medicine and the Law."—ED. L.

RADIUM TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a letter from Lieut.-Colonel Spencer Mort in your issue of June 2nd, referring to some remarks I made in the House of Commons on cancer. From the letter I understand that the writer claims much more for radium in the treatment of cancer than I was aware of. When he writes: "Surely . . . it would be much more helpful and hopeful to all sufferers from carcinoma if these could be induced to come forward *at the earliest moment* (my italics) with a hope of painless cure by short-wave radiations?" I wonder how many of those qualified to judge will agree with him. I would like to ask: If any early case of operable carcinoma presented itself to any competent surgeon to-day, how many would use radium in preference to removal by operation? If few or none of my remarks are justified—if there are some, then I was not aware of this fact. My remarks were intended to prevent delay until cases became inoperable. My experience of uterine and rectal cases which were treated by radium was most unfortunate, as none of my cases was cured. Some had their life prolonged, but all died from the disease. I am well aware of the *assistance* that radium can give, but as the question raised, and the position taken, by Colonel Spencer-Mort is so very important, I hope that a definite pronouncement may be made for my benefit and for those who, through fear of operation, delay to seek advice.—I am, Sir, yours faithfully,

A. VERNON DAVIES, M.B., M.P.

London, June 4th, 1928.

*** We have recently set out the evidence—surgical, radiological, and physical—that if radium can effectively be brought in contact with a cancer, the growth can be made to disappear. The technique for so doing appears to have been mastered in the local treatment of carcinoma in certain situations. So much, at least, can be said safely.—ED. L.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—I have seen this morning in the *Daily Express* what purports to be an interview with me reproducing my words. Many of the things reported I did not say; others were said with the distinct understanding that they were private. The message I permitted to be published was the fact, learned from my journey to New Zealand, that closer intercommunication between the medicine of the motherland and the Dominions would be of enormous value. Of course no proof of the intended article was submitted to me.

I am, Sir, yours faithfully,

VICTOR BONNEY.

Devonshire-place, W., June 6th, 1928.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, JUNE 5TH.

Re-Assembly of the House of Commons.

The House of Commons re-assembled on June 5th after the Whitsuntide recess.

Rates Paid by Voluntary Hospitals.

Captain CROOKSHANK asked the Minister of Health what was the total sum paid in rates in each of the last two years by the voluntary hospitals in England and Wales.—Sir KINGSLEY WOODS, Parliamentary Secretary to the Ministry of Health replied: I regret that statistics giving the information desired by my hon. and gallant friend are not available.

Miners and Silicosis.

Mr. JENKINS asked the Secretary for Mines if he had taken any steps to ascertain what number of mine workers in the South Wales coalfield had been unable to follow their employment due to silicosis; and if any compensation had been paid in respect of any of these cases.—Sir WILLIAM JOYNSON-HICKS replied: I regret that, for the reasons indicated in my reply on the 3rd of last month, the information asked for in the first part of the question is not available. No compensation is payable at present to workmen who contract this disease in the coal-mining industry; but I have asked the Departmental Committee on Workmen's Compensation for Silicosis to advise on the terms of the scheme under Section 47 of the Workmen's Compensation Act for the industry, and for this purpose I have appointed to the Committee representatives of each side, nominated by the Mining Association and the Miners' Federation respectively.

Mr. JENKINS asked the Secretary for Mines whether his Department had taken any steps to take tests as to the quantity of silica in the strata of the coal mines of South Wales.—Commodore H. D. KING, Secretary for Mines, replied: Yes Sir, the inquiries which have been made as the occurrence of silicosis among miners working in hard rock in coal mines have included analyses and other tests of the rock dust.

Adulteration of Milk.

Sir WALTER DE FRECE asked the Minister of Health whether there was any increase, according to official statistics, in the adulteration of milk; whether all local authorities were expected annually to carry out any fixed or approximate number of tests; and whether he would take steps to see that such tests were generally carried out.—Sir KINGSLEY WOOD replied: The official statistics indicate a progressive decrease in the adulteration of milk, the percentage of samples reported by public analysts as adulterated or below the presumptive standards being 6·9 in 1927 as compared with 7·4 in 1926 and 9·3 in 1920. There is no specific requirement as to the number of samples to be taken annually by a local authority, but it is the practice of my department to communicate from time to time with those authorities which do not seem to be taking a sufficient number to provide a proper check on adulteration.

Exemption Orders for Cocaine and Cocaine Hydrochloride.

Mr. FENBY asked the President of the Board of Trade whether he was aware that the exemption orders applied for in about July, 1926, under Section 10 (5) of the Finance Act, 1926, in respect of cocaine and cocaine hydrochloride, being products liable to duty under Part I. of the Safeguarding of Industries Act, 1921, had not yet been issued; that his department refused to issue these exemption orders, although the products in question were still not made in His Majesty's Dominions; that, in consequence, hospitals and the general medical services, who were the chief consumers of these materials, which had to be imported, had during the past two years been compelled to pay more than would otherwise have been the case; and would he take steps to issue the exemption orders in question forthwith.—Sir PHILIP CUNLIFFE-LISTER replied: The manufacture of cocaine and cocaine hydrochloride in substantial quantities has been carried on in this country for some time past under the authority of the Home Office. I understand that these materials will shortly be available for disposal, and the conditions for exemption from duty are, therefore, not satisfied.

OPENING OF WEMBLEY HOSPITAL.—On June 2nd, the Duke of York, accompanied by the Duchess, opened a hospital at Wembley which has been built at a cost of £20,000, all of which has been raised during the past three years. Twenty beds are available, and the number can be doubled at a comparatively small cost.

Obituary.

GEORGE EDWARD SHUTTLEWORTH, B.A. LOND., M.D. HEIDELBERG, M.R.C.S. ENG.

THE death occurred, on May 28th, as we noted last week, of Dr. George Edward Shuttleworth, for many years medical superintendent of the Royal Albert Asylum, Lancaster. By his death psychological medicine has lost one who for many years was one of its outstanding figures, and that section of it which is concerned with Mental Deficiency has lost one acknowledged by all to be its leading authority.

Shuttleworth who was 86 years of age at the time of his death, received his medical training at King's College Hospital, and Heidelberg, where he graduated in medicine in 1869. His connexion with mental deficiency began shortly after qualification when he was appointed assistant medical officer to Earlswood Asylum, at the time under the superintendency of Dr. J. Langdon-Down. In 1870 he was selected to be Superintendent of the Royal Albert Institution at Lancaster, and he remained there for 23 years. On leaving Lancaster he came to London, where he took up consulting work, and from this time until he was nearly 80 years of age, when he retired from practice, he was the doyen of this branch of medicine. His advice was sought by high and low from all parts of the country, and many patients were sent to him from abroad. He was a prominent and regular attendant at scientific meetings, and an active and highly valued member of practically every society or body which was in any way concerned with the interests of mental defectives. He was, in fact, for many years the heart and centre of most of the work in this country on mental deficiency.
